Use of evidence is now stated and recommended in the calls for projects from the 3 regional health agencies. In Martinique, use of evidence helped professionals to improve their practice, to add value to their project, etc. In PACA, local actors created documents in order to transfer capital information selected from evidence-based data they analysed. In Normandie, evidence in prevention is now seen as decision help and integrated in regional programs and in the process contractualization with field professionals.

Conclusions:

In Martinique, the methodological support they benefit from the TC-REG project helped to understand, use and transfer evidence. In PACA, the professionals testified that methodological support and work conditions they benefited were essentials in the process to allow comprehension, integration and popularization of evidence. In Normandie, the existing dynamic of KT will be used to develop evidence-based programs.

A reflexive analysis of 10 years of knowledge transfer activities in French-speaking West Africa

Valéry Ridde

V Ridde[1], *C Dagenais*[2]
[1]CEPED, IRD, Paris, France
[2]Equipe Renard, UQAM, Montréal, Canada
Contact: valery.ridde@ird.fr

In French-speaking West Africa, the use of evidence for decision-making in the health sector is relatively rare and poorly studied. In addition, very few KT strategies are implemented in an explicit, organized and evidence-based manner. Thus, over the past 10 years, we have organized or been involved in multiple KT activities organizations. During these occasions, we were able to test the use of a variety of KT tools (policy brief, deliberative workshop, knowledge brokering, dissemination workshop, capitalization, video, etc.) in several countries such as Burkina Faso, Benin, Mali, Niger, Senegal. These activities were carried out with numerous operational partners (IGO, NGO, UN) and researchers from these countries.

The objective of this presentation is 1) to present examples of our practices to illustrate what can be done in Francophone West Africa, and 2) to propose a reflective analysis in order to produce lessons learned to improve our practices. The two authors met several times to carry out their analysis on the basis of their practical experience in these different countries. The results confirm the importance of studying, and taking into account in advance, all KT activities, the decision-making processes that vary significantly between countries and within countries. A thorough knowledge of the political and social contexts and of the tenuous and continuous relationships with decision-makers is a favourable factor for KT. It is essential to involve potential users of research knowledge throughout the research process but also in the creation and adaptation of KT tools. In Africa, the significant presence of international development aid, its actors and resources have a significant influence on the ability to mobilize actors and require that they be taken into account in the organization of KT strategies.

This communication will conclude with a proposal of some operational recommendations to improve our collective KT practices in French-speaking Africa.

Knowledge translation: how can NGOs contribute to bridging the gap between researchers and health practioners?

Sophie Calmettes

S Calmettes[1], *G Breton*[1], *E Guillard*[1], *L Pizarro*[1]
[1]Therapeutic Solidarity and Initiatives for Health - Solthis, Bagnolet, France
Contact: sophie.calmettes@solthis.org

Solthis is an international health NGO that has been working for 15 years hand-in-hand with local stakeholders, health practitioners, research institutions and donors in West and Central Africa. Our goal is to promote prevention and access to quality care through health systems' strengthening interventions in the field of infectious diseases and reproductive, maternal, newborn, adolescent and child health. In order to promote our interventions' efficacy, sustainability and scalability, we use three modalities of action: capacity building, operational research and advocacy.

As an NGO with recognized expertise, solid stakeholder foundations and particularly positive working relations with Ministries of Health, we are in a potentially key position to be involved in KT. As a matter of fact, we carry out KT activities as part of our daily activities: utilising knowledge to improve practices of health care workers, being involved in research priority setting, conducting operational research directly or in partnership with research institutions, advocating with policy makers to use research findings, having inputs into policy making.

To make the most of this unique position and to achieve better results, we have started to move from the usual dissemination activities often limited and concentrated at the end of projects, to more strategic and participatory KT activities, planned from the onset of the project and with dedicated resources.

This communication will go through the evolution of KT activities included in our projects and the analysis of barriers and facilitating factors for an effective knowledge translation (eg. adoption at scale of an innovation in public health programs and practices). In conclusion, we will formulate some recommendations in terms of: i) practical KT activities that NGOs can undertake; ii) how to build relevant partnerships between NGOs and researchers, and iii) advocacy for donors to recognize, and fund KT activities and their evaluation.

10.P. Workshop: Better ask those who are concerned: co-creation in participatory epidemiology and health promotion

Organised by: EUPHA (HP), EUPHA (PHMR), Robert Koch Intistute, Charité Berlin, University of MedicineChair persons: Nicole Rosenkötter - EUPHA (PHMR), Mario Bach - Germany
Contact: christiane.stock@charite.de

Objectives:

The hallmark of participatory research is the establishment of equitable research partnerships with a diverse group of stakeholders such as public health professionals, health activists and community representatives. This includes co-creation as a guiding principle that informs several aspects of the research process. Originally, co-creation is a concept from management science and software design and is focused on achieving synergistic effects through user participation in design processes. Co-creation in participatory epidemiology and health promotion aims to improve the life of those who are subjects of research by giving them a stake how studies are carried out, respectively how health promoting services, programmes or products are designed and provided. However, implementing and realizing co-creation is challenging. Participation asks for a systematic reflection of underlying power relations in the research process through dialog, recursive methods of understanding, and joint planning.

This skills building seminar will present relevant co-creation concepts and methods. Additionally, illustrative examples from research practice are provided and will outline ways for implementing co-creation in the context of participatory epidemiology and health promotion. The seminar starts with a brief introduction on epistemological principles and ethical norms of participatory health research and state of the art definitions of co-creation. This presentation is followed by an introduction of how co-creation is impacting epidemiological research with regard to several aspects of the research process. Next, a project is presented in which co-creation informed the development of a virtual reality game in the field of alcohol prevention. Finally, participants will be split in two groups to have the opportunity to share thoughts on certain aspects of participatory research and co-creation in a poster discussion. More specifically, we aim to discuss:

- Does co-creation differ in the contexts of participatory epidemiology and health promotion? And if so how?
- What is needed to realize co-creation processes in practice?

The seminar targets everyone working in the field of population health monitoring and health promotion. The timetable is as follows: Introduction, principles and definitions (15 min), participatory epidemiology and co-creation (15 min), co-designing in prevention and health promotion (15 min), poster discussions (30 min), plenary discussion and roundup (15 min).

Main messages

- Co-creation is a way to improve the relevance of research findings, services and products for public health practice and the involved communities.
- Co-creation processes are vital to embrace the creativity of users and to ensure relevance and community ownership for health promotion programmes and services.

Key messages:

- Co-creation is a way to improve the relevance of research findings and products for various stakeholders.
- Co-creation is vital to embrace users' creativity and to ensure community ownership.

Co-Creation in participatory epidemiology

Mario Bach

M Bach[1], C Santos-Hövener[1], S Jordan[1]
[1]Robert Koch Institute, Berlin, Germany
Contact: BachM@rki.de

Background:

Participatory epidemiology aims to involve public health professionals, health activists, and community representatives in epidemiological studies. Paramount are equitable research partnerships for identifying the causes of health problems, generating data, and finding ways to address health related issues. Alongside the research process, co-creation informs various aspects of participatory epidemiology.

Methods:

A scoping review was conducted to develop the conceptual foundations of participatory epidemiology. Workshops with staff from public health administration and public health practitioners were held to check feasibility of the concept for public health monitoring, policy making and the development of relevant public health recommendations. From this research, principles and practices of co-creation were identified.

Results:

Co-creation is of importance for participatory epidemiology. 1) Methodologically: Co-creation asks to apply multiple perspectives (research, practice, communities) in data collection and synthesis, what may require the adaption of a given study design. 2) Research practice: Co-creation in participatory epidemiology means producing epidemiologic evidence while contributing to concrete public health interventions, two goals that have to be balanced. 3) Personal attitudes: In participatory epidemiology academic researchers, practitioners, and community representatives are requested to acknowledge each other as co-researching partners, which can be challenging for each of them.

Conclusions:

Co-creation is a prerequisite for establishing equitable research partnerships. In participatory epidemiology, co-creation offers ways to produce meaningful knowledge for research and practice.

Main messages:

- Participatory epidemiology offers ways of producing epidemiologic evidence while contributing to public health practice.
- Co-creation is a prerequisite, way, and attitude to conduct meaningful research, hopefully for all of those who are involved.

Co-designing a virtual reality game for alcohol prevention

Christiane Stock

C Stock[1], L Vallentin-Holbech[2], T Dietrich[3], G Majgaard[2]
[1]Charité Berlin University of Medicine, Berlin, Germany
[2]University of Southern Denmark, Odense, Denmark
[3]Griffith University, Brisbane, Germany
Contact: cstock@health.sdu.dk

Issue/problem:

Health promotion programmes that train social competencies in situations adolescents commonly encounter are likely to minimise the social influence and social pressure to drink or use other substances. In the Virtual Reality (VR) TestLab project, an innovative VR learning tool is developed that shows a typical party situation for young people. The game user can navigate through the party making their own choices, which result in different outcomes.

Description of the problem:

The Living Lab method guided the development of the VR learning tool. During the four phases of the Living Lab process three groups of 16-25-year-old students were involved, as well as two prevention practitioners, three prevention scientists, three VR game designers and one film production expert.

Results:

At the initial exploration stage of the Living Lab framework a list of key concepts/scenes were co-created with all stakeholders. At the concept stage students were invited to co-create a film script for the VR game. The prototype stage involved students as actors for the scenes, which were then finally recorded in technical collaboration with game developers and the film production expert. Post production, the finalised scenes were integrated into a game engine to develop the interactive branching narrative. At the innovation stage the group was invited to examine, explore and test its usability and share their experiences, thoughts, and attitudes.

Lessons:

The Living Lab framework was useful in order to structure the co-creation process into meaningful phases and to ensure that all stakeholders were consulted throughout the development of the VR game. The Living lab framework gave 'voice' for the end-users (young people and practitioners) to actively engage in the co-creation process.

Main message:

This first Living Lab application in drug prevention contributes to a better understanding of the importance of involving users of health promotion products and services through co-creation.

10.Q. Skills building seminar: Designing accessible environments for disabled people for training, expression of views & co-working

Organised by: EHESP French School of Public Health
Chair persons: William Sherlaw - France, Marie Cuenot - France
Contact: William.Sherlaw@ehesp.fr

Objectives:

We will actively explore ways of building bridges between people with disabilities and the non-disabled community. We aim to show an inclusive society will necessitate significant changes in ways of working with people with disability.

Organization:

The workshop is divided into 2 parts. In Part 1 through two 15 minute presentations we offer illustrations of participatory practice with people with disabilities and families taken from different, but allied sectors. Presentation 1: ParticipaTIC is an accessible transnational on-line training platform for disabled persons organization leaders. Specifically we will address how challenges of designing an accessible platform were met while highlighting outstanding tensions between on-line accessibility and other dimensions of digital design. Such issues are relevant not just to on-line instruction, but also to creating a truly inclusive society. Presentation 2: This describes how the European Academy of Childhood Disability has picked up the gauntlet of including families and organized a special 3 hour family session at their annual conference in Paris. Focus group style activities have been designed to a) enable the expression of families with respect to what matters for the happiness and well-being of their children with disability b) enhance the participation of families to improve knowledge, practice and understanding between families and health, social and educational professionals. Building on the Part 1 presentations, Part 2 of the workshop will involve a skills building activity (50 mins). This has been extensively used in disability and discrimination training at EHESP with master students, and civil servants. It uses role-play to raise awareness of the rights and needs of people with disabilities. Participants draw plans for redesigning hospital car parking to take into account the needs of all people that use the hospital. (This may be considered as a microcosm of society.) In a first phase (20 mins) groups of 6-10 participants brainstorm. Certain participants are then asked to step into the shoes of disabled people and work with others to produce plans. (20 mins) Feedback is offered on the process and the plan. (10 mins) In conclusion (10 mins), participants will briefly be asked to suggest improvements for the accessibility of a scientific conference such as EUPHA. Conclusion: Fully inclusive practice may be in tension with taken-for-granted habits. The extent of adaptations necessary may be surprising to non-disabled people. They go beyond using sign-language, induction loops, braille, and speech synthesis. They also include Easy to Read & Understand for people with intellectual disabilities. Beyond such adjustments challenges for including people with disabilities within training, meetings, and participatory fora are raised. We suggest that our 3 examples illustrate the challenge facing society and social services in co-designing truly inclusive practice and environments.

Key messages:

- Through placing people in the shoes of people with disabilities, participants will come to learn that inclusion also impacts on the very process of consultation and participation.
- Inclusion will involve creating accessible and participatory environments in order to offer equal opportunities for learning and participation adapted to different groups and capacities.

ParticipaTIC: Lessons from developing accessible on-line training for disabled people's leaders

Marie Cuenot

M Cuenot[1], *W Sherlaw*[1]
[1]Department of Human and Social Sciences, EHESP, Paris, France
Contact: marie.cuenot@ehesp.fr

The ParticipaTIC Erasmus+ project led by the EHESP School of Public Health in partnership with disability organizations and associations from France, Belgium, Switzerland, and Romania has co-designed an accessible digital platform. In line with the 2010-2020 European strategy and the United Nations Convention on the rights of disabled persons we aim to strengthen the competences of the leaders of disabled persons' organizations to defend the rights of disabled people, and to develop participation. ParticipaTIC offers 4 modules on 'What is disability?', 'Competencies for disability organization leaders', 'the United Nations Convention' and 'How to carry out a local accessibility analysis'. Different contrasts, font size, speech synthesis, captioned videos and content summaries in 'Easy to read and understand' French are available together with a cloned platform in Romanian and English. Two guides have also been produced on 1) on-line accessibility and 2) co-constructing an on-line accessible platform. Beyond the deliverables, adapting on-line instruction to the different capacities of people with disabilities raises many issues. New competencies for accessible design are needed. Tradeoffs between content, pedagogical style and accessibility seem inevitable. On-line activities need adaptations but these may be complex and costly. Taken-for-granted assumptions about what is attractive, and well-designed are called into question when designing for people with visual, auditory, and intellectual impairments. Lessons from ParticipaTIC are remarkably similar to those of participatory thinking design: advance in small steps, evaluating successive design phases with people with disabilities for fitness of purpose. Ultimately trainers need to redesign themselves to take into account unsuspected worlds, those of our fellow citizens with different capacities. Important lessons beyond the world of on-line instruction for the building of a truly inclusive society have emerged.

Facilitating the collective expression of parents of disabled children at a scientific conference

Alain Chatelin

A Chatelin[1], *R Scelles*[2], *W Sherlaw*[3]
[1]Fondation Paralysie Cérébrale, Paris, France
[2]ClipsyD (EA 4430), Université Paris Nanterre, Paris, France
[3]Department of Human and Social Sciences, EHESP, Rennes, France
Contact: achatelin@fondationparalysiecerebrale.org

The European Academy of Childhood Disability is an academic association with over 500 members (health, social work and educational professionals working with children with disability) from some 35 different countries. The Academy wishes to put families at the heart of its agenda. Partnership with families has the potential to improve care and education outcomes and renew practice. It may also facilitate understanding between professionals and families. To this end for the annual conference in Paris a series of structured interactive group activities have been designed to facilitate the sharing of experience and expression of families and to gather their concerns. These activities designed by disability specialists in partnership with family representatives call on small group work "world café" style focus group methodology. They are structured, varied, interactive and take place in a specially organized conference session over 3 hours. Sensitive feedback is provided by experienced pediatricians in the childhood disability field. Parents provide narratives of significant experiences for their children prior to the conference. These are shared in groups of 3. Questions explored include "What matters for the happiness of your children? "Please give examples of things which have happened in your child's life which seem to be key experiences" Relating to the concept of F-words, (Rosenbaum, Gorter, 2011) parents have also been asked to consider different dimensions of their children's well-being such as friendship, functioning, fitness, family, fun, and future. Group discussions are noted, recorded, retranscribed and analysed allowing, the gain of insights and providing possible building blocks for professional training. Such qualitative data allows new topics and research on a joint family-professional agenda to emerge. These may be tackled at future conferences thus building bridges between specialists and families.

4. POSTER WALKS
1.R. Health promotion, health literacy

EnCLASS: an innovative project merging 2 international surveys (HBSC/ESPAD) among French students

Emmanuelle Godeau

E Godeau[1,3], *V Ehlinger*[3], *S Spilka*[2,4]
[1]EHESP, Rennes Cedex, France
[2]OFDT, Paris, France
[3]UMR 1027, INSERM-Université Toulouse III, Toulouse, France
[4]CESP, Faculté de Médecine, Université Paris Sud, Faculté de Médecine UVSQ, INSERM, Université Paris-Saclay, Villejuif Paris, France
Contact: emmanuelle.godeau@ehesp.fr

Problem:

For two decades, France has taken part in two ''competing'' school-based, cross-national surveys exploring the health behaviors and well-being of adolescent (Health Behavior in School-aged Children (HBSC) survey, 11-13-15 year-olds) and their substance use (European School Project on Alcohol and other Drugs (ESPAD), 15-16 year-olds).

Description of problem:

Since 2010, French data is provided at national level by grade rather than age. This allowed providing a continuous observation of health behaviors among adolescents, looking at the temporal spread of substance use and providing a better understanding of the role of school as a setting for adolescents' health. But the difficulty of participating every 4 years in two big surveys remained.

Effects of changes:

In 2018, France decided to conduct the 2 surveys in a unified and simultaneous way across middle- and high-school. This project is called 'National Survey in Middle- and High-school for Adolescents on Health and Substances', EnCLASS, explicit acronym easy to pronounce and remember in French. If the main objective of ''merging'' these surveys is to improve the monitoring of health behaviours and substance use throughout adolescence, it also allows a significant gain regarding preparation, coordination and organization of the fieldwork, hence of overall costs, while ensuring perfect comparability of data at international level.

Evolution of data visualization on substance use will be used to illustrate the challenges and improvements of such a process, based on data collected in 2018 among more than 20,000 representative secondary-school students.

Lessons:

In addition to a greater facility of interpreting and reading findings, presenting data throughout secondary school grades improves its impact and use in a public health perspective and allowing identifying operational targets for prevention and health promotion in schools, as classes are their main settings.

Key messages:

- EnCLASS is unique in Europe, it ensures an excellent comparability of data at international level while providing an innovative national monitoring of adolescent health behavior, including drug use.
- Further, by its improved quality, perspective and relevance, EnCLASS can contribute to Public health policies analysis regarding school-students in France in a less expensive and better way.

What if we combine Quit and win and individual approach to help smokers quit at the community level?

Jasmina Kovacevic

J Kovacevic[1], *D Zombori*[1]
[1]Public Health, Public Health Institute of Pozega Slavonia County, Pozega, Croatia
Contact: dr.jasminakovacevic@gmail.com

Issue:

Tobacco eventually kills up to a half of its users. Helping smokers who wish to quit is one of the six cost effective interventions listed by World Bank to decrease smoking harm. Tobacco Control Scale in 2016, shows diversity in approaches and coverage to help smokers quit across Europe. Comprehensive interventions are most effective. Combining contest, financial incentives, individual approach and triggers (start of Lent or other) could be implemented in other settings.

Description of the problem:

Contest to motivate smokers for a quit attempt and individual help provided, has been conducted yearly since 2015 in a local community in Pozega-Slavonia County in Croatia. Data on all participants from 2015 through 2018 contests were collected by questionnaires and long term smoking status (6 months) evaluated by phone interviewing. Statistical analysis was conducted in SPSS. The objective was to determine how effective in helping smokers quit is a novel combination of evidence-based approaches ''Quit and win'' and individual support in local setting and to establish certain smokers characteristics as possible predictors of outcome.

Results:

Data for 153 participants were collected. There were more (54%) male participants. Participants mean age was 35.8 years (range 18-67). Short term (30 day) abstinence rate was 73.9% (113/153) and out of those 34.1% (31/91) abstained long term (6 months). Long term follow-up was 80.5% (91/113). Overall, long term quit rate was 23.7% (31/131). There were no statistically significant differences in short and long term quit rates depending on age, sex, education, employment or socio-economic status, pack-year measure or personal success estimates.

Lessons:

Comprehensive contest approach was found to be effective in helping smokers quit. Interest for implementation was shown by several counties and cities in Croatia. Effectiveness regardless of personal and social characteristics of contestants shows potential in different settings.

Key messages:

- Comprehensive interventions that include contest, financial incentives, individual approach and triggers in smoking cessation helped one in four involved smokers to quit.
- This approach has potential for implementation in diverse local communities as no difference in quit rates in different sex, age or socioeconomic groups were detected.

Effective elements of Dutch care-physical activity initiatives for low socioeconomic status adults

Annemarie Wagemakers

L S Mulderij[1], *F Wolters*[1], *M A E Wagemakers*[1], *K T Verkooijen*[1]
[1]Social Science Group, Health & Society, Wageningen University & Research, Wageningen, Netherlands
Contact: annemarie.wagemakers@wur.nl

Background:

In care-physical activity (care-PA) initiatives, primary care and sports collaborate to stimulate PA among adults at risk of lifestyle related diseases. Preliminary results of Dutch care-PA initiatives for low socioeconomic status (SES) adults indicate that these initiatives successfully lower participants' body weight and improve quality of life. However, insight into elements that make these initiatives work is lacking. Therefore, this research aims to unravel the effective elements of care-PA initiatives for low SES adults.

Methods:

Concept Mapping (CM) was used as tool to identify and cluster the effective elements. Nineteen Dutch health promotion experts individually listed as many elements as they felt were of importance to the effectiveness of care-PA initiatives. Next, each expert was asked to cluster the elements and to score them on importance. Then, CS Global MAX software was used for multidimensional scaling and a hierarchical cluster analysis to develop a cluster map. Finally, the cluster map was presented, discussed, and refined in a group meeting with 11 of the experts.

Results:

The experts came up with 113 unique effective elements of care-PA initiatives for low SES adults, clustered into 11 clusters: 1) approach of professionals, 2) barriers experienced during the programme, 3) local embedding, 4) customisation of the programme to target population, 5) social support, 6) methods within the programme, 7) competencies of professionals, 8) accessibility of the programme, 9) actions within the programme, 10) recruitment of participants, and 11) intersectoral collaboration.

Conclusions:

A valuable overview of the effective elements of care-PA initiatives for low SES adults was created. The results can be used to improve existing care-PA initiatives and to develop new ones targeted at low SES adults at risk of lifestyle related diseases. This may eventually help to reduce health inequalities between low and high SES adults.

Key messages:

- Concept mapping has been a useful group-based tool to obtain information on the effective elements of care-PA initiatives, in which individual input from health promotion experts has been collected.
- The overview of effective elements of care-PA initiatives for low SES adults as presented in this study is valuable for the development of care-PA initiatives specifically targeted at low SES adults.

Examining multi-layer constraints on activity engagement among older adults

Sunwoo Lee

S Lee[1,2]
[1]Faculty of Physical Culture, Palacky University Olomouc, Olomouc, Czech Republic
[2]Faculty of Physical Education and Sports, Charles University, Prague, Czech Republic
Contact: sunwoo.lee@upol.cz

Background:

Social and cognitive activities motivate the older adults to develop individual aspirations, newfound sources of pleasure, and engagement in later life. The current study aimed to examine a wide range of factors that might impede older adults’ participation in activities, and to provide strategies to manipulate the constraints in the promotion of active ageing.

Methods:

We used data drawn from a sample of the Survey of Health, Ageing, and Retirement in Europe (SHARE) wave 7.0. The study sample comprised 48,742 European elderly, aged between 65 and 105 years (54% female). Multiple questionnaire items were used to assess various constraints including socio-demographic factors, personality, social supports, health and psychological indicators. Activities included social and cognitive activities and also moderate physical activities. A series of regression analysis was performed to examine the hypothesized relationships between study variables.

Results:

Those older adults who reported negative perception of neighborhood environment ($p < .001$), poor health ($p < .001$), chronic diseases ($p < .001$), and frequent loneliness and depression ($p < .001$) were less likely to participate in social and cognitive activities. Moderate-level of physical activities were strongly related to the health variables ($p < .001$) and social supports ($p < .001$). Among the demographic variables, age was highlighted as the most predictable factor for the decreased participation in activities.

Conclusions:

In order to promote diverse forms of activities in later life, we should be better-informed about different nature and variability of the constraints among the older adults. Improving accessibility to the activities such as ageing-friendly facilities and home-oriented social service and recreation programs can help older adults more engage in daily activities.

Key messages:

- Older adults experience varied constraints on social, cognitive and physical activities.
- Public health should improve accessibility to diverse forms of activities in later life.

Reliability and Validity of Disability Literacy Scale for Medical School Students

Sevil Aydoğan

S Aydoğan[1], *E Atay*[1], *S Metintaş*[1], *Z Demirtaş*[1], *EE Öcal*[1], *S Çalışkan Pala*[1], *D Oktar*[1], *A Mutlu*[1], *MF Önsüz*[1]
[1]Department of Public Health, Eskişehir Osmangazi University Medicine Faculty, Eskişehir, Turkey
Contact: aydogan.sevil@gmail.com

Background:

Disability literacy is the ability to perceive definition of disabled person, their characteristics, difficulties in daily life and solution suggestions, their rights and false thoughts and orientations about them. The aim of the study was to develop the Disability Literacy Scale (DLS) to determine the disability literacy of medical school students with a high probability of encountering disabled people.

Methods:

This study was conducted in 1110 medical school students in 2018-2019 academic year. By using literature 97 questions were collected. DLS was created with 22 questions by taking expert opinions. Correct answer was scored as 1, while wrong or ’do not know’ answer as 0. In order to evaluate the reliability of the scale, item total score correlation and internal consistency (Cronbach’s alpha) analyzes and exploratory and confirmatory factor analysis were used for construct validity.

Results:

Of the 51.1% students were female and their age ranged from 17-40, the mean was 21.1 ± 2.2. After the scale development study, the scale consisted of 14 items and 3 sub-dimensions. Scale items explain 43.21% of total variance and factor loadings ranged from 0.37-0.80. The Cronbach’s alpha coefficient was 0.61, 0.64, 0.51 for communication, health problems and social life sub-dimensions, and 0.68 for the whole scale. The fit of scale and the fit index were found to be acceptable after confirmatory factor analysis. In the last form of the scale, the score that can be taken from scale range 0-14. It was accepted that by increasing of the score, disability literacy level was increased. The mean score of students was 9.79 ± 2.57 and the median was 10.0. The scores obtained from DLS were found to be lower in the first 3 grades ($p < 0.001$), low level mother and father education ($p < 0.001/p = 0.012$) and who have not yet taken lesson about disability ($p = 0.021$).

Conclusions:

DLS is a valid-reliable tool for assessing disability literacy levels of medical school students.

Key messages:

- It is essential to place disability related lessons from the earliest grades of medical school curriculum.
- In the literature, DLS seems the first scale about disability literacy and needs to be tested in large communities.

Validating a model & self-assessment tool to measure organizational health literacy in hospitals

Jürgen M Pelikan

J Pelikan[1], *P Nowak*[1]
[1]Health Promoting Hospitals, The Austrian Public Health Institute, Vienna, Austria

Contact: juergen.pelikan@goeg.at

Background:

The European Health Literacy Survey (HLS-EU) demonstrated that in many European countries a considerable proportion of the population has limited health literacy (HL), that there is a social gradient for HL and that HL is associated with use of health services. Furthermore research mostly from the US also showed that HL of patients has detrimental effects not only on use but also on outcomes of health care. Therefore in the US the concept of the Health Literate Health Care Organization (HLHCO) has been developed by IOM to make health services more sensitive to the needs of patients with limited HL.

Methods:

Based on the IOM concept, a more comprehensive model of a Health Literate Health Care Organization fulfilling criteria of WHÓs health promoting setting approach has been developed. A set of standards and indicators according to quality management criteria (ISQUA) to measure the organizational HL of a hospital has been constructed, tested and validated in 9 different kinds of hospitals by a team in Vienna. This model and measurement tool has been translated to English and other languages and been used and validated also in other countries (Belgium, Italy, Taiwan). By an international working group of the international Health Promoting Hospitals and Health Services network an international version of the model and tool has been developed and will be tested in different countries.

Results:

The model and self-assessment tool has been demonstrated to be acceptable, feasibly, valid and useful to start self-assessment and improvement of organizational HL in different types of hospitals and health care systems.

Conclusions:

Organizational HL of health services matters for use and quality of health care of patients. Measuring organizational HL of hospitals by a validated instrument can support development of a more health literate health care organization and by that improve quality of care and tackle the health gap.

Key messages:

- Health literacy matter for health care and can be measured and improved on a personal and on an organizations or systems level to improve quality of care and tackle the health gap.
- A model and self-assessment instrument to measure organizational health literacy of hospitals has been developed and validated to support hospitals to improve their organizational health literacy.

Digital health literacy among adults living in the community in Singapore

Jade Soh

JS Soh[1], *AW Wong*[1]

[1]Health and Social Sciences, Singapore Institute of Technology, Singapore, Singapore

Contact: jade.soh@singaporetech.edu.sg

Background:

this study aimed to determine the level of digital literacy in adult Singaporeans in the community and its association with demographic characteristics, physical activity, self-rated health and bodily pain, and to identify the health needs of frequent internet users.

Methods:

a cross-sectional survey was carried out among individuals living in Punggol, Singapore on 2 June 2018. Survey data were using a 20-minute self-completion questionnaire. The questionnaire included the validated 8-item eHealth Literary Scale (eHEALS), the validated 4-item Exercise Stage of Change Questionnaire, a single item on self-reported health status and Likert scale items to assess level of bodily pain in the last 4 weeks and how much that pain interfered with normal work. The questionnaires and interviews were administered by registered nurses. Quota sampling was used to obtain sufficient numbers from different ethnic groups for analysis of the survey: the initial target was 120 Chinese, 60 Malay and 60 Indian individuals, one per household.

Results:

survey data were collected from 279 individuals (49.6% female), including 197 (71.1%) Chinese, 47 (17.0%) Malay, 18 (6.5%) Indian and 15 (5.4%) others. The mean age was 35.6 (SD 11.3). The eHEALS score had a mean of 29.4 (SD 6.2) out of a maximum of 40. Self-reported health status was positively associated with pain in the last 4 weeks (Kendall's $\tau = 0.141$, $p = 0.007$), how much that pain interfered with normal work (Kendall's $\tau = 0.160$, $p = 0.003$) and the Exercise Stages of Change score (Kendall's $\tau = -0.271$, $p < 0.001$). The correlation between the two pain variables was strong (Kendall's $\tau = 0.582$, $p < 0.001$). The only one of these measures significantly related to the eHEALS score was the Exercise Stages of Change score (Kendall's $\tau = 0.104$, $p = 0.030$). From linear regression models, the only independent variables consistently associated with the eHEALS score were age ($B = -0.090$, $p = 0.006$) and having a mobile phone plan ($B = 8.171$, $p < 0.001$).

Key messages:

- Digital health literacy was negatively related to age and positively related to having a mobile phone plan.
- The study finding suggest the need to identify individual Singaporeans with poor e-health literacy and provide them with remedial education.

Health Literacy of Hearing-Impaired High School Students, Some of the Problem, and their Expectations

Kamer Gür

K Gür[1], *G Dolaner*[1], *R Turan*[1]

[1]Department of Public Health Nursing, 2 Marmara University, Istanbul, Turkey

Contact: kamergur@gmail.com

Purpose:

This study aims to determine hearing-impaired students' levels of health literacy, problems when they receive healthcare service and their expectations.

Methods:

This descriptive study was conducted on 88 hearing-impaired high school students over 15 years of age. The data collection tools used in the study are ‘‘Form of Problems Experienced When Receiving Healthcare Service’’, ‘‘Form of Expectations from Healthcare Service’’, and Turkey Health Literacy Scale (THLS-32). The researchers know sign language. The Health Sciences Faculty granted approval for the study (04.12.2017-255). The families were informed of the program through the school administration, and their consent was obtained.

Results:

70.5% of the students had inadequate, 19.3% had limited, 2.3% had adequate and 8% had excellent health literacy levels. Those who had communication problems with the doctor (25%), those who misused the prescribed medication (13.6%) and those who could not use the medication without help (43.2%) had low THLS scores (<0.05). Those who stated that they did not understand what the nurses said (43.2%) and the health education materials (56.8%) and those who reported that they were confused when they had more than one appointment (20.5%) had significantly low THLS scores (<0.05). 55.7% of them expected that their prescriptions or care procedures were to be given in writing, and 87.5% expected them to be told in sign language.

Conclusions:

Most of of the participants have significantly weaker general health literacy. Students with low THLS scores have less understanding of the given information and have problems with health workers.

Main messages: This can create disparities and inequalities in the use of healthcare services and in the health outcomes.

Key messages:

- This can create disparities and inequalities in the use of healthcare services.
- This can create disparities and in the health outcomes.

Beliefs About Medicines: Differences in cholesterol treatment adherence among the Visegrad countries

Klara Boruzs

K Boruzs[1], *Z Fekete*[2], *V Dombrádi*[1], *G Bányai*[1], *A Nagy*[3], *R Horne*[4], *K Bíró*[1]

[1]Department of Health Systems Management and Quality Management in Health Care, University of Debrecen, Debrecen, Hungary
[2]Institute of Behavioral Sciences, University of Debrecen, Debrecen, Hungary
[3]Department of Preventive Medicine, University of Debrecen, Debrecen, Hungary
[4]UCL School of Pharmacy, University College London, London, UK
Contact: boruzsklara@gmail.com

Background:

Raised cholesterol is a risk factor for cerebrovascular and cardiovascular diseases. New cholesterol guidelines highlight more personalized risk assessments and new cholesterol-lowering drugs for people at the highest risk for cardiovascular disease.

Methods:

The aim of our study was to investigate the possible differences in the beliefs about the necessity and concerns regarding lipid-lowering drugs among the Visegrad Group countries. For this the Beliefs About Medicines Questionnaire (BMQ-Specific) was used. The statistical analyses included 235 Czech, 205 Hungarian, 200 Polish, and 200 Slovak respondents, all of who were taking cholesterol lowering drugs.

Results:

After comparing the answers of the citizens of the Visegrad Group countries, no statistically significant difference could be found regarding the concerns about the lipid-lowering drugs. However, related to the beliefs in necessity, a significant difference was shown between Poland and Hungary for the benefit of Polish participants. These results suggest, that the citizens of Visegrad Group countries do not differ regarding their beliefs about the fear of the treatment, while the beliefs about benefits are the most emphasized among the Polish citizens and less among the Hungarian citizens.

Conclusions:

While policy makers in the Visegrad Group countries can use the same strategy to address the concerns regarding cholesterol lowering medication, the reasons behind the difference in the beliefs in necessity should be further investigated in order to implement country specific interventions.

The research was funded by the GINOP-2.3.2-15-2016-00005 project which is co-financed by
the European Union under the European Regional Development Fund.

Key messages:

- No differences exist regarding the concerns for cholesterol lowering medication among the Visegrad Group countries.
- Concerning necessity significant differences were observed among the same countries, which prompts further research questions.

1.S. Migrants and access to care

Trust in health care systems Arab minority, Jewish immigrant and non-immigrant

Ronit Pinchas-Mizrachi

R Pinchas-Mizrachi[1,2], *N Daoud*[2]

[1]Ramat-Gan Academic College, Ramat-Gan, Israel
[2]Ben-Gurion University of the Negev, Beer-Sheva, Israel
Contact: pinchas.ronit@gmail.com

Background:

The objective of this study was to examine the level of trust towards Israel's health care services (HCS) among Palestinian-Arab minority, Jewish immigrant, and non-immigrant Jewish citizens. Previous studies have shown that minorities and immigrants have less trust in health care system (HCSys), which might represent a barrier in access to, and utilization of HCS.

Methods:

We obtained cross-sectional nationwide census data from the 2017 Social Survey of the Israel Central Bureau of Statistics. We studied levels of trust in the HCSys based on a survey question: 'Do you have trust in the healthcare system?'' We conducted logistic regression analysis within and between the study groups to compare levels of trust, after adjustment for different relevant covariates in different models.

Results:

Compared to non-immigrant Jews, Arabs had higher trust in the HCS (odds ratio (OR) = 3.08, 95% confidence intervals (CI) = 3.06,3.10) and compared to non-immigrant Jews, immigrant Jews had more trust (OR = 1.96, 95% CI = 1.94,1.98), even after adjusting for gender, age, education level, religiosity level, perceived discrimination, self-rated health status, HCS use, and having private health insurance. The variables that predicted trust in the HCSys were different in each ethnic group.

Conclusions:

Contrary to our hypothesis and to previous research, Arab and immigrant Jewish respondents in our study had greater trust in the HCS compared to non-immigrant Jews. This might relate to different expectations among our study groupsof the patient-caregiver relations which might affect the access to and utilization of HCS and finally might affect the quality of care.

Key messages:

- Exceptionally, in Israel, the Arab minority and Jewish immigrants have more trust in the health care system compared with non-immigrant Jews.
- More research is needed to understand how trust among minority groups relates to the patterns of utilization of HCS and raises question regarding the quality of care.

Understanding racism in Swedish healthcare

Sarah Hamed

SH Hamed[1], *Beth Ahlberg*[1,2], *Hannah Bradby*[1], *Suruchi Thapar-Björket*[3]

[1]Department of Sociology, Uppsala University, Uppsala, Sweden
[2]Skaraborg Institute for Research and Development, Independent Research Institute, Skövde, Sweden
[3]Department of Government, Uppsala University, Uppsala, Sweden
Contact: sarah.hamed@soc.uu.se

Background:

Despite the removal of the term 'race' from statutory documents in Sweden, after the Second World War, racism continues to exist in various institutions including healthcare. Racism can persist in the absence of a biological notion of 'race' but becomes harder to explain when there is no official recognition. There is evidence of discrimination by patients and healthcare professionals, although fragmented and under-researched. As healthcare should be built on equity and solidarity, accounts of racism constitute a serious breach. Our research focuses on conceptualising racism in healthcare in Sweden to develop means of improving equity in care for populations characterised by migration-driven diversity.

Methods:

Data from 28 qualitative interviews with both patients and healthcare professionals in Sweden was collected.

Results:

Preliminary results indicate that patients from minority ethnic groups report that healthcare providers deem their symptoms as insignificant, due to their ethnicity. Consequently, they experience a loss of integrity and trust in healthcare, often leading them to avoid seeking healthcare. Healthcare professionals conceptualise racism in varied ways, ranging from denying racism, normalising and individualising racism to viewing racism as a structural problem. Patients did not report their experiences of racism, as racism was often subtle. Likewise, healthcare professionals mostly chose not to report their experiences for fear of being constructed as difficult colleagues.

Conclusions:

The lack of space for discussing racism within healthcare constitutes a problem for healthcare professionals and patients and contributes to rendering experiences of racism invisible. This may be detrimental for achieving responsive healthcare and creates an unhealthy working environment for some healthcare professionals.

Key messages:

- Promoting a constructive dialogue on racism in healthcare.
- Aiding in developing anti-racist practices in healthcare.

Information and communication technology-based interventions to support healthcare in migrants

Anna Odone

FG Vaccaro[1], A Oradini Alecreu[1], A Scardoni[1], B Frascella[1], GP Vigezzi[1], A Odone[1], C Signorelli[1]
[1] School of Public Health, Vita-Salute San Raffaele University, Milan, Italy
Contact: anna.odone@mail.harvard.edu

Background:

Advances in the field of Information and Communication Technology (ICT) are revolutionizing healthcare, while massive migration flows and cross-border populations' transit impose the planning, implementation, and evaluation of new integrated healthcare services and programmes. Nevertheless, no conclusive evidence exists on the vast potential offered by ICT to promote healthcare in migrant populations.

Methods:

We carried out a systematic review following the Preferred Reporting Items for Systematic Reviews and Meta-Analysis guidelines to retrieve, pool and critically appraise all the available evidence on the effectiveness of ICT-based interventions to support the healthcare provision to migrant and in-transit populations in Europe. We searched the electronic databases Medline and Embase, relevant grey literature and consulted with experts in the field. We restricted the area of interest to EU/EEA countries and included studies providing original quantitative data.

Results:

Out of 127 retrieved records, 53 (42%) met the inclusion criteria. Included studies were classified in the following four interventions: implementation of healthcare services (47%), patients' education (26%), healthcare services' monitoring (17%), and interventions on providers (10%). The most relevant data refer to telemedicine, prevention interventions, and healthcare data sharing and the most represented specific health-topic is that of mental health (26%). We present available data qualitatively and quantitatively pooled by country, type of ICT, target population and health topic.

Conclusions:

Selected ICT-based interventions have been implemented in Europe to promote healthcare in migrant populations; however, in most cases, no monitoring and evaluation exist on their impact, effectiveness, and cost-effectiveness. Strengthened efforts are needed to identify, plan, implement and evaluate effective interventions and share best practices to protect in-transit populations' health.

Key messages:

- Information and Communication Technology (ICT) offer great potential to promote health-care in migrant populations.
- Effective ICT interventions and best practices should be shared across Europe.

Racial discrimination and biological dysregulation among Indigenous adults: The role of culture

Cheryl Currie

J Copeland[1]
[1] Health Sciences, University of Lethbridge, Lethbridge, Canada
Contact: cheryl.currie@uleth.ca

Background:

Racial discrimination is an ongoing social concern that requires public health solidarity to address. Indigenous peoples in many countries report high levels of discrimination across a variety of life domains, particularly when they migrate into urban centres for school or work. Discrimination has wide-ranging impacts that go beyond mental distress to include alterations in stress biomarkers across multiple systems. This study examined the impacts of discrimination on multisystem biological dysregulation among urban Indigenous adults in Canada, operationalized through allostatic load; and the role that Indigenous cultural continuity might play in resilience.

Methods:

This cross-sectional study collected data from 150 Indigenous adults attending university in a small city in western Canada between 2015 and 2017 (M age: 28 years). Allostatic load (AL) was measured as a composite of 7 biomarkers assessing neuroendocrine, cardiovascular, metabolic, and immune system function. Bias-corrected and accelerated bootstrapped linear regression models examined associations adjusted for confounders.

Results:

Past-year discrimination was significantly and linearly associated with increased AL adjusting for age and income ($B = 0.17$, $p = 0.02$). Among adults with low cultural continuity, past-year discrimination was associated with AL in models adjusted for age and child discrimination ($B = 0.17$, $p = 0.01$), with past-year discrimination and the full model explaining 24% and 41% of the variance in AL; respectively. Among adults with high cultural continuity, past-year discrimination was not associated with AL, and the full model explained 1% of the variance in AL.

Conclusions:

Past-year racial discrimination was an adverse event capable of influencing multisystem biological dysregulation among Indigenous adults, independent of age and income. Indigenous cultural continuity may promote biological resilience against racism within this population.

Key messages:

- Racial discrimination was associated with multisystem biological dysregulation among urban Indigenous adults, controlling for age and income.
- Indigenous cultural continuity buffered the impact of discrimination on biological health.

Evaluation of the use of standardized methods to identify mental health problems among refugees

Sara Delilovic

S Delilovic[1,3], K Lonnroth[2,3], A Hagstrom[3]
[1] LIME, Karolinska Instutitet, Stockholm, Sweden
[2] PHS, Karolinska Institutet, Stockholm, Sweden
[3] Implementation and Evaluation, Center for Epidemiology and Community Medicine, Stockholm, Sweden
Contact: sara.delilovic@ki.se

Background:

The number of refugees arriving and residing in Sweden remains high. They represent one of the most vulnerable subpopulations in the country, who carry a disproportional part of the disease burden. Information on health status, health determinants and the extent to which refugees get access to needed services is limited. In Sweden refugees are offered a free-of -charge health examination (HE). Yet, standardized mental health screening is often neglected as a part of the HE.

A pilot project aimed to initiate early mental health screening was implemented.

Methods:

The Refugee Health Screener-13 (RHS-13) was identified as an efficient, valid, and reliable tool for assessing mental health in this population and was integrated into the HE. The RHS-13 was administrated by nurses conducting the HE at two primary health care centers in Stockholm.

Results:

During the one-month pilot 80 individuals were screened. The majority originated from Syria, DR Congo and Afghanistan and the distribution by migration background were 58% quota refugees, 35% asylum seekers and 8% others (family reunification and undocumented migrants). Of those screened, 30% screened positive for risk of mental health (cut off $\geq$11). Out of those who screened positive, 29% screened for mild mental health, 33% for moderate mental health and 38% for severe mental health problems. No statistically significant differences in RHS score were found according to country of origin, sex and age. The results are preliminary. Implementation will continue for 12 months at 4 primary health care centers.

Conclusions:

This pilot demonstrated feasibility of RHS-13 in routine care. The findings reinforce the need for standardized guidelines and procedures for mental health screening of refugees. Routine mental health screening should be a part of the overall comprehensive HE, which could improve systematic monitoring of mental health care needs for refugees and ensure access to appropriate mental health care.

Key messages:

- Standardized procedures for identifying mental health problems among refugees is feasible and can identify health needs while ensuring equitable health examinations.
- Standardized procedures for identifying mental health problems among refugees is feasible and can identify health needs while ensuring equitable health examinations.

Migrants and access to healthcare: the Italian public health residents action plan

Leuconoe Grazia Sisti

L Mammana[1], C Milani[1], P Bordin[1], M Del Riccio[1], LG Sisti[1], C Salvia[1], G Raguzzoni[1]

[1]Inequalities Working Groups, Italian Hygiene Society Committee of Residents, Rome, Italy

Contact: leuconoe.sisti@gmail.com

Background:

Fighting health inequalities have been included in the WHO Sustainable Development Goals as a priority. Migrants are between the most vulnerable individuals and healthcare interventions, also during the post-migration period, should be oriented, context-specific and aimed at identifying reasons underlying inequalities, as suggested by the recent WHO report 'No public health without migrant health'. The "Inequality Working Group" of the Italian network of public health (PH) residents of the Italian Society of Hygiene, Preventive Medicine and Public Health (SItI) aims at identifying an interdisciplinary approach suitable to detect barriers to healthcare access for migrants in different Italian regions. Secondly, we aspire to develop some strategies to overcome unequal healthcare access.

Methods:

Focus group methodology was applied to set working group educational needs, priorities of action and working plan. Moreover, we implemented a network between various professionals involved in migrant healthcare, particularly with the Regional Groups of the Italian Society of Migration Medicine (SIMM).

Results:

After a period of peer-to-peer education about social determinants of health and migration, we reviewed Italian policies about migrants' healthcare and considered potential discrepancies from WHO recommendations. Furthermore, we mapped practices regarding access to care for migrant population and we focused on causes underlying unequal healthcare access.

Conclusions:

Although with regional differences, migrants have limited access to healthcare services and therefore represent a vulnerable subpopulation.

Key messages:

- Fighting against the barriers that limit access to care for migrants is a priority for health systems.
- PH residents have a relevant role in identifying and defining critical issues, designing enforcement measures and implementing advocacy actions.

A first assessment of the electronic health insurance card for asylum seekers in Berlin

Nora Gottlieb

N Gottlieb[1], V Ohm[2], M Knörnschild[2]

[1]Health Care Management, Technical University Berlin, Berlin, Germany

[2]Berlin School of Public Health, Berlin, Germany

Contact: nora.gottlieb@tu-berlin.de

Background:

Healthcare provision for asylum seekers differs across Germany. Most states use treatment vouchers as proof of eligibility; i.e., asylum seekers must first obtain a voucher from the welfare office to access healthcare. Since 2016 several states have introduced an electronic health insurance card (EHIC) for asylum seekers that enables access to care akin to statutory insurance. The EHIC has reanimated an old debate about asylum seekers' health benefits. Opponents claim that medical costs will rise if control over healthcare access is eased. Proponents argue that the EHIC reduces costs through the cutback of administrative workloads and improves access to care. Evidence for either position is scarce.

Goal:

The study goal was to assess the 2016 EHIC introduction in Berlin to enable evidence-informed decision-making.

Methods:

We analyzed claims data that were retrieved from the Berlin Senate Administration and ten semi-structured in-depth interviews with key informants. Interviews were recorded, transcribed and subjected to thematic analysis using ATLAS.ti software. Ethical clearance was obtained.

Results:

Our study found an overall positive evaluation of the EHIC. Although the introduction implied extra efforts and total administrative workloads remained unaltered, the EHIC was said to have the following advantages as compared to treatment vouchers: 1) It simplifies certain work processes and 2) allows for unprecedented financial transparency and control. 3) It eases access to care with 4) no increase in medical costs. Finally 5) the EHIC signifies equality and integration for asylum seekers.

Conclusions:

In light of our study results the common economic arguments against greater inclusion of asylum seekers into public healthcare systems appear unfounded. On the contrary, the example of the EHIC shows that inclusion can create win-win-situations by improving healthcare access, whilst keeping medical costs constant and advancing financial transparency.

Key messages:

- In Germany there is a long-standing debate whether easing access to care for asylum seekers will increase health costs.
- Our case study shows that, on the contrary, the introduction of an electronic health insurance card for asylum seekers can both improve access and have organizational and economic benefits.

Health assessment of newly arrived refugees to the Municipality of Copenhagen, Denmark

Mathilde Horn Andersen

M Andersen[1], *H Winther Frederiksen*[1], *M Ahmadi*[1], *A Kruse*[1], *M Nørredam*[2]
[1]Section of Immigrant Medicine, Copenhagen University Hospital, Hvidovre, Copenhagen, Denmark
[2]Danish Research Centre for Migration, Ethnicity and Health, University of Copenhagen, Copenhagen, Denmark
Contact: mathilde.horn.andersen@regionh.dk

Background:

Research data on the health status of newly arrived refugees is sparse. Newly arrived refugees and family reunified in The Municipality of Copenhagen has since 2016 been offered a general health assessment. These assessments are conducted by clinicians with expertise in refugee and migrant health from the Section of Immigrant Health. This study describes the sociodemographic characteristics and the burden of disease in this population.

Methods:

In this cross-sectional study the population consists of adult patients examined January 2017 to February 2019. Clinicians performed the health assessment including a questionnaire regarding sociodemographics, medical history, symptoms, traumatic events during/before migration, a clinical examination and blood samples.

Results:

The population had an equal presentation of males (N = 81) and females (N = 79) primarily from Syria (33%) and Iran (29%). The median age was 31,5 years (SD = 10,9). 67% had ≥8 years of schooling, while 11% had a maximum of 2 years. More than half had experienced war and 50% persecution. 76% suffered from Vitamin D deficiency, 31% of B12 deficiency and 12% of anemia. Few suffered from infectious and somatic diseases, yet many experiences symptoms such as pain (53%) and headaches (54%). 33% presented with symptoms of PTSD.

Conclusions:

A high frequency of micronutrition deficiency was prevalent in the refugee group. Furthermore, many suffered from physical symptoms while very few had serious somatic issues. Numerous traumatic experiences were reported and 33% presented with symptoms of PTSD. The data is presumably a reflection of the healthy migrant bias.

Key messages:

- Despite refugees presumably being tested pre-entry and at holding level, they still suffer several health issues when granted asylum.
- Many newly arrived refugees suffer from micronutrition deficiency. These conditions are easily treated and could enhance the overall health of the individual.

Subjective status comparisons and depressive symptoms among migrants and refugees to Germany

Jens Hoebel

A Polizzi[1], *C Santos-Hövener*[1], *E Mauz*[2], *T Lampert*[1], *J Hoebel*[1]
[1]Unit of Social Determinants of Health, Robert Koch Institute, Berlin, Germany
[2]Unit of Mental Health, Robert Koch Institute, Berlin, Germany
Contact: j.hoebel@rki.de

Background:

Prior research has identified perceptions of relative social status to affect mental health. We investigated whether migrants to Germany who perceive that they would have a higher relative social status if they were still in their country of origin experience more depressive symptoms than those who perceive no such status discrepancy.

Methods:

Cross-sectional data were derived from a random sample of residents in the Berlin-Brandenburg region with a Croatian, Polish, Romanian, Syrian and/or Turkish citizenship (n = 728). Participants' perception of their relative social status in Germany was measured using the MacArthur Scale of subjective social status (SSS). An adapted version of this scale was used to assess respondents' hypothetical SSS in their country of origin if they had not migrated. Depressive symptoms were measured with the eight-item depression scale of the Patient Health Questionnaire. Diagonal reference models were used to examine whether discrepancies between the two status ratings were associated with depressive symptom severity.

Results:

Most respondents reported a higher (35.6%) or similar (49.0%) hypothetical SSS in their country of origin compared to their SSS in Germany. Respondents whose SSS in Germany was lower than their hypothetical SSS in their country of origin experienced the most severe depressive symptoms. In the diagonal reference models, this association remained statistically significant ($p < 0.05$), even after adjusting for objective socioeconomic position and other covariates. The pattern was similar for both refugees and non-refugees.

Conclusions:

Our findings indicate that perceptions of having a lower social status in Germany than hypothetically in one's country of origin are concomitant with poorer mental health among migrants. Prospective data are needed to address questions of causation and the direction of effects.

Key messages:

- Migrants who perceived that they would have a higher social status if they had not left their country of origin reported higher depressive symptoms than those with no such status discrepancy.
- This association persisted after adjusting for objective socioeconomic position in Germany.

Your Health, Your Faith: HIV prevention with African faith-based communities in Germany

Tanja Gangarova

T Gangarova[1], *A Bakambamba*[1]
[1]Structural Prevention, Deutsche AIDS-Hilfe e.V. (DAH), Berlin, Germany
Contact: tanja.gangarova@dah.aidshilfe.de

Migrants are disproportionally affected by HIV/AIDS in Germany, with about every third new HIV diagnosis given to a person who has migrated to Germany. More than half of HIV new diagnoses among migrants are people from sub-Saharan African countries. Because infections are not just brought from the countries of origin but also occur in Germany, HIV prevention services must be better tailored to the needs of migrants.

Your Health, Your Faith (2016-2018) is a community-based participatory health project that aims to improve the involvement of African faith-based communities in HIV prevention services. The project is conducted by the National AIDS Service Organization in collaboration with partners from different African communities, African pastors, AIDS service organizations (ASOs) and researchers from the Ludwig Maximilian University of Munich.

Teams of African activists, African pastors and ASOs have been built in eight German cities. All partners were invited to a series of concept workshops in Berlin in order to define together prevention contents, methods and forms of cooperation. Together, they developed a concept for preaching preventive messages in church settings and scenarios for a mobile educational theatre group.

To date 65 multilingual events have been held at various African churches, reaching approximately 5000 people. The results of the project has been evaluated on a multi-case basis, with quality standards being compiled for prevention events in African churches. In the course of the project, the participants designed a video that illustrates the prevention work in African Church communities. At the request of the pastors involved, a mobile training series on HIV/Aids for African pastors has been developed with the support of medical doctors.

Key messages:

- HIV prevention in African churches and cooperation between African churches, public health authorities and ASOs is possible and promising.
- Communication via pastors has proven useful, as have supporting theatre performances that facilitate communication about taboo subjects such as HIV/AIDS.

Predictors of Late Presentation for HIV among HIV-positive Tajik Migrants to the Russian Federation

Daniel Bromberg

DJ Bromberg[1,2], *MM Tate*[3], *K Alaei*[4,5], *S Karimov*[6], *D Saidi*[6], *A Alaei*[4,6]
[1]Department of Social and Behavioral Sciences, Yale University, New Haven, Connecticut, USA
[2]Center for Interdisciplinary Research on AIDS (CIRA), Yale University, New Haven, Connecticut, USA
[3]Yale University, New Haven, Connecticut, USA
[4]Institute for International Health and Education, Albany, NY, USA
[5]School of Public Health, Drexel University, Philadelphia, PA, USA
[6]Republican AIDS Center, Tajikistan Ministry of Health, Dushanbe, Tajikistan
Contact: dan.bromberg@yale.edu

Between 800 thousand and 1.2 million citizens of Tajikistan currently live in the Russian Federation, one of the only countries where the HIV epidemic continues to worsen. Given the previously reported barriers to healthcare access for migrants in to the Russian Federation, and the rapidly expanding HIV epidemic in Eastern Europe and Central Asia, this present study set out to determine whether these barriers impact late presentation with HIV upon their return to Tajikistan. This study uses data from the Tajikistan Ministry of Health surveillance system. The dataset contains all new known HIV diagnoses between 2006 and 2018. At time of diagnosis, patients are interviewed by staff of AIDS centers, complete routine intake forms and complete medical exam and related forms by doctors. HIV-positive returned migrants who had lived in the Russian Federation ($n = 770$) were included in final data-analysis after data cleaning. Data were analyzed using three logistic (logit) models. The unadjusted logistic model found that for every year spent in the Russian Federation, the risk of late presentation for an HIV-positive Tajikistani migrant increases by 10.3% (95% CI: 5.5-15.3). The saturated multivariate model showed that when holding all study variables constant, the risk of late presentation for an HIV-positive Tajikistani migrant increases by 9.5% (95% CI: 2.6-16.9). The parsimonious multivariate model showed that when current age and region of origin are held constant, the risk of late presentation for an HIV-positive Tajikistani migrant increases by 6.3 (95% CI: 1.1-11.8). Even when other potential predictors are included in the logistic model, only age and length of time abroad remain statistically significant. The results of this paper suggest that if the Russian Federation were to adopt a reciprocal policy, it might improve treatment outcomes of migrant laborers. Further research is needed to explicate the causal pathways of the associations found in the present analysis.

Key messages:

- Structural factors are the strongest predictors of HIV late presentation among returned Tajik migrants to the Russian Federation.
- Further research is needed to explicate the causal pathways of the associations found in the present analysis.

Does the ehealth card facilitate access to healthcare from the point of view of refugees in Germany?

Judith Wenner

K Rolke[1], *J Wenner*[1], *O Razum*[1]
[1]School of Public Health, Bielefeld University, Bielefeld, Germany
Contact: judith.wenner@uni-bielefeld.de

Background:

The municipalities in the federal state of North Rhine-Westphalia (NRW) decide autonomously how to organize access to health care for refugees: either with electronic health card (eHC model) or with health care voucher (HcV model). The eHC model is often expected to facilitate access to health care and to reduce bureaucratic barriers. However, there are only few analyses of how refugees perceive the two models and their corresponding access to health care.

Methods:

A total of 28 problem-centered interviews with refugees were conducted in three municipalities in NRW (two with HcV and one with eHC model). Sampling was purposive, aiming to achieve a maximum variation of interview partners with regard to age, gender, chronic illnesses, pregnancy and parenthood. The interviews were conducted with the support of translators in the language of the respondents' choice. Interviews transcripts were evaluated by content analysis using the software atlas.ti.

Results:

Refugees using both the eHC and HcV models report mostly positive experiences when seeking care - both in terms of treatment and interaction with physicians or non-medical staff. The first contact with the health care system was rarely organized by refugees themselves in both models, but mostly with the support of social workers, friends, or family members. The main perceived difference between the models was that in the HcV model, urgent treatment required additional waiting time.

Conclusions:

Access to care is assessed similarly well by refugees in all municipalities. The additional approval process for treatment by the social welfare office in HcV municipalities may lead to a delayed treatment. Formal and informal support is particularly important for newly arriving refugees to help them navigate the complex German health system.

Key messages:

- The implementation of one access model alone does not facilitate access to health care for refugees.
- Formal and informal support is necessary for refugees to gain access to the health system.

2.R. Overweight, underweight and diet

Variation in uptake of Healthy Start Food Vouchers in the Six Health and Social Care Partnerships

Michael Fleming

E Salim[1], *S Scott*[2]
[1]Institute of Health and Wellbeing, University of Glasgow, Glasgow, UK
[2]Public Health Department, NHS Greater Glasgow and Clyde, Glasgow, UK
Contact: michael.fleming@glasgow.ac.uk

Background:

The primary aim of this study was to assess the difference in uptake levels of Healthy Start Food Vouchers, a means tested benefit to afford nutritious food, between 6 Health and Community Partnerships (HSCP) in Greater Glasgow and Clyde (GGC). Our secondary aim was to explore possible reasons for the observed variation.

Methods:

Routinely collected Healthy Start data for the months of August to September 2017 were obtained from the UK Department of Health. Postcode sectors were matched up with their corresponding HSCPs in GGC. Analysis looked for associations between uptake rates and various HSCP area-based characteristics.

Results:

Large variations were observed within GGC. Chi-square test showed a significant association between uptake and HSCP area ($P < 0.0005$). Trend analysis of uptake with area deprivation ($P = 0.001$) and resource allocation ($P < 0.001$) was also significant. Subjective analysis of trend direction suggested that uptake increased with deprivation and resource allocation of the HSCP.

Conclusions:

Significant trends were found and the observed patterns suggested that the relationship between uptake rates and HSCP area is more complex than the geographical characteristics alone. Future studies need to look at the difference in management and awareness of the voucher scheme between Maternity teams in HSCPs.

Key messages:

- There is significant variation in the uptake of means tested benefits with some areas having a nearly forty percent of eligible individuals not receiving available support.
- A qualitative approach is required to determine the causes of low uptake rates of benefits and improve the effectiveness of maternity teams in different areas.

Prenatal exposure to extra vitamin D from fortification and risk of developing coeliac disease

Caroline Moos

C Moos[1,2], KS Duus[1,2], P Frederiksen[1], B Heitmann[1,4], V Andersen[2,3]
[1]Research Unit for Dietary Studies at The Parker Institute, Bispebjerg and Frederiksberg Hospital, Copenhagen University Hospital, Copenhagen, Denmark
[2]Research Unit for Molecular Diagnostic and Clinical Research, University Hospital of Southern Denmark, Aabenraa, Denmark
[3]Institute of Molecular Medicine, University Hospital of Southern Denmark, Odense, Denmark
[4]The Department of Public Health, Section for General Practice, University of Copenhagen, Copenhagen, Denmark
Contact: moos.caroline@gmail.com

Introduction:

Few studies have examined the role of maternal diet in relation to development of autoimmune diseases such as coeliac disease (CD). In Denmark, cancellation of mandatory vitamin D fortification of margarine in June 1985 provides this opportunity. This study examined if prenatal exposure to extra vitamin D from food fortification or season of birth were associated with a decreased risk of developing CD later in life. If low prenatal vitamin D levels are a risk factor, there are immediate, cheap and easy public health implications.

Methods:

This register based study has a partially ecologic design. The two entire cohorts were created using information available from the Danish birth registry and development of CD (ICD-8 269 ICD-10 K90) over 30 years was retrieved from the Danish National Patient Register. Logistic regression analysis was used to generate odds ratios and 95% confidence intervals.

Results:

There was a lower odds ratio of developing CD (OR: 0.811 95% CI 0.655; 1.003) from the exposed birth cohort adjusting for sex and season of birth. There was a significant season effect particularly for children born in autumn (OR 1.6 95% CI 1.16; 2.21) and born summer (OR 1.5 95% CI 1.1;2.1) when compared to children born in winter.

Conclusions:

The results indicate a potential protective effect of a small extra intake of vitamin D from food fortification by pregnant women in relation to the risk of their offspring developing CD. This conclusion is further supported by the results showing that summer born children, where first half of gestation occurred during the dark winter season, had a higher risk of CD. This research lends support for the reconsideration of vitamin-D food fortification in Denmark.

Key messages:

- Exposure to even a small amount of vitamin D prenatally may protect against developing coeliac disease later in life.
- Association between season and CD indicates that vitamin D may play an important role in relation to fetal programming.

Interventions for gestational diabetes prevention: An umbrella review of meta-analyses of RCTs

Demetris Lamnisos

K Giannakou[1], E Constantinou[1], D Lamnisos[1]
[1]Department of Health Sciences, School of Sciences, European University Cyprus, Nicosia, Cyprus
Contact: D.Lamnisos@euc.ac.cy

Background:

Gestational diabetes mellitus (GDM) is a common pregnancy complication, defined as glucose intolerance with onset or first recognition during pregnancy, in women without diabetes history during pregnancy. It is a major cause for adverse maternal and fetal outcomes and affects around 15% of all pregnancies. GDM is considered to be a risk factor for future metabolic conditions and cardiovascular disease.

Methods:

An umbrella review was performed to identify systematic reviews and meta-analyses of randomized controlled trials for GDM prevention in order to summarize evidence and evaluate the validity of the interventions. We searched PubMed, the Cochrane library and ISI Web of Science from inception to March 2019. For each meta-analysis we estimated the summary effect size by random-effects and fixed-effects models, the 95% confidence interval, the 95% prediction interval, the between-study heterogeneity expressed by I2, evidence of small-study effects and evidence of excess significance bias.

Results:

Six-teen eligible papers were identified providing data on 39 associations. Eighteen (46%) associations had nominally statistically significant findings at $P < 0.05$, while only one (3%) remain significant at P < 10-6 under the random-effects model. Eight (21%) associations had large or very large heterogeneity. Evidence for small-study effects and excess significance bias was found in 5 (13%) and 2 (5%) associations, respectively. Only one intervention presented robust evidence for a convincing association: prenatal exercise compared with no exercise (RR 0.62, 95% CI: 0.52-0.75). It was supported by > 500 cases, 95% prediction intervals excluding the null, no large heterogeneity, small-study effects, or excess of significance.

Conclusions:

Prenatal exercise shows the strongest consistent evidence. The findings from our study highlight the importance of patient education about lifestyle modifications to reduce risk of GDM.

Key messages:

- Prenatal exercise could lower the risk of GDM based on solid epidemiologic evidence.
- Obesity, pregnancy hypertension and other metabolic conditions could be prevented as well.

Relationship between perception of emotional home atmosphere and fruit and vegetable consumption

Monica Hunsberger

M Hunsberger[1], HAG Elsayed[1]
[1]Epidemiology and Social Medicine, University of Gothenburg, Goteborg, Sweden
Contact: monica.hunsberger@gu.se

Objective:

Consumption of fruits and vegetables (FV) among adolescents falls below recommendations in many Western countries. The impact of socio and emotional aspects of family life on adolescent dietary behavior may contribute to this, yet remains under-investigated. This study examines the association between adolescents' perceptions of emotional home atmosphere (EHA) and their FV consumption frequency.

Design:

A food frequency questionnaire was used to assess FV consumption frequency. EHA was assessed by an eight item measure with three subscales: perceived home warmth, strictness and relational tension. EHA subscales were used as binary variables: a score equal to or above the median value was considered as a higher perception while a score below the median was considered as a lower perception of the EHA in question. Country differences in meeting the European 5/day recommendations are described. Further, the association between EHA and FV consumption frequency is investigated using multiple linear regression.

Setting: Regional examination centers in eight European countries.

Subjects: 3196 adolescents aged 12-18 years.

Results:

The mean FV consumption frequency was 3.27(SD = 2.84) times/day. Only 16.1% of boys and 18% of girls in our study sample met the recommendation of 5 times/day. After controlling for age, sex, education level of the parents and country of origin, perceived home warmth was associated with a 16% higher FV consumption frequency ($P < 0.001$; 95% CI 9-22).

Conclusions:

FV consumption frequency was suboptimal in the survey areas. Interventions targeting perceived warmth as a component of EHA could potentially have a positive effect on adolescents' dietary behavior.

Key messages:

- The home atmosphere may be an important driver of fruit and vegetable consumption.
- Fruit and vegetable consumption is often suboptimal and efforts should be made to target adolescent consumption behaviors.

Impact of an excise tax on the consumption of sugar-sweetened beverages in Catalonia, Spain

Miguel Ángel Royo Bordonada

MA Royo Bordonada[1], C Fernández Escobar[1], L Simón[2], B Sanz Barbero[1], J Padilla[3]
[1]Academic Affairs, Spanish National School of Public Health, Institute of Health Carlos the Third, Madrid, Spain
[2]National Center of Epidemiology, Institute of Health Carlos III, Madrid, Spain
[3]Primary Care Health Center Isabel II, Madrid Health System, Madrid, Spain
Contact: mroyo@isciii.es

Background:

Sugar-sweetened beverage consumption is contributing to the obesity epidemic. On 28 March 2017, Catalonia enacted a law levying an excise tax on sugar-sweetened beverages for public health reasons. The purpose of this study is to assess the impact of the tax on the consumption of sugar-sweetened beverages in Catalonia (Spain).

Methods:

Before-and-after study to assess changes in the prevalence of consumption of sugar-sweetened beverages among 1929 persons aged 12 to 40 years residing in low-income neighbourhoods of Barcelona (intervention) and Madrid (control). Beverage consumption frequency was ascertained via a validated questionnaire administered during the month prior to the tax's introduction (May 2017) and again at one year after it had come into force. The effect of the tax was obtained using Poisson regression models with robust variance.

Results:

While the prevalence of regular consumers of taxed beverages fell by 41% in Barcelona as compared to Madrid, the prevalence of consumers of untaxed beverages remained stable. The main reason cited by more than two-thirds of those surveyed for reducing their consumption of sugar-sweetened beverages was the increase in price, followed by a heightened awareness of their health effects.

Conclusions:

The introduction of the Catalonian excise tax on sugar-sweetened beverages was followed by a reduction in the prevalence of regular consumers of taxed beverages.

Key messages:

- This is the first study to show the efficacy of the Catalonian excise tax to reduce the prevalence of regular consumers of sugar sweetened beverages by residents of low-income neighbourhoods in Spain.
- Our results, along with the remaining scientific evidence on the subject, would justify the extension of the measure to the rest of Spain for public health reasons.

How the French Nutri-Score can impact sales of processed-foods? A complex system perspective

Eric Breton

E Breton[1,2], O Ode[1], T Oikonomidi[3], & the EHESP MPH working group on Nutri-Score[1]
[1]EHESP French School of Public Health, Rennes, France
[2]Lab Arènes/CNRS/UMR 6051, Rennes, France
[3]CRESS INSERM UMR1153, Paris, France
Contact: eric.breton@ehesp.fr

Background:

Nutri-Score (NS) is France Front-of-Pack Food Labelling System to provide at-a-glance information about the nutritional quality of pre-packaged food products. Based on the Food Standards Agency nutrient profiling system, its algorithm generates a score by taking into account the presence of both the harmful and beneficial contents in food. In this presentation, we report on our analysis of the logic model of NS and on its potential impact on the production and marketing of processed foods.

Methods:

We reviewed the scientific and grey literature on NS to identify its potential mechanisms and loci of change. We also appraised the policy against Meadow's leverage points for system change.

Results:

The official adoption of the NS algorithm is instrumental in modifying both consumer food-related behaviours and food industry corporate practices. The algorithm takes 3 forms: 1) the front-of-pack logo indicating an integrated colour/letter score for the product, 2) mobile device applications which help consumers assess the nutritional value of food products even without an affixed logo, 3) nutritional parameters which influence food manufacturing decision-making in the industry. NS can trigger different drivers of corporate practice. From the current uptake trends, small and medium size food manufacturers appear more likely to welcome the NS Logo as a means to stand out against the multinational corporations presently dominating the market. As for the capacity of NS to transform the existing systems of producing and marketing processed foods, we find that it is mostly by changing the flow of information. NS presents new information, previously inaccessible to consumers, to support the population in making healthier food choices by providing a means for nuanced nutritional comparisons between food products of the same category.

Conclusions:

We conclude on the potential evolution of Nutri-Score and how its uptake by food corporations may be fostered.

Key messages:

- Nutri-Score's impact is through: the front-of-pack logo; nutrition apps; and as a parameter of food industry decision-making.
- Nutri-Score impacts the flow of information of the processed-food system.

Salt reduction in bread: Is it enough? Preliminary results of a HIA in Portugal

Joana Raquel Raposo Santos

J Santos[1], P Braz[1], A Costa[2], L Costa[2], M Santos[3], R Brazão[3], J Alves[4], I Lopes[5], A Guerreiro[6], T Almeida[2]
[1]Epidemiology, Institute Public Health, Lisbon, Portugal
[2]Health Promotion, Institute Public Health, Lisbon, Portugal
[3]Nutrition, Institute Public Health, Lisbon, Portugal
[4]School of Public Health, Lisbon, Portugal
[5]DGE, Ministry of Education, Lisbon, Portugal

[6]Public Health, Regional Health Administration, Faro, Portugal
Contact: joana.santos@insa.min-saude.pt

Issue:

Health Impact Assessment (HIA) is a methodology that aims at assessing the impact of policies in health. A pilot HIA is in progress to kick off the implementation of this methodology in Portugal with the support of the World Health Organization (WHO). In this context, the impact of a nation-wide policy that intends to achieve a maximum of 1 g of salt/100 gr in bread is under assessment.

Description of the issue:

In 2017, Portugal approved a protocol between the industry and other stakeholders to gradually decrease the amount of salt in bread, as this is the main source of salt intake. The purpose of this study was to assess the impact in blood pressure from current (1.4 gr) to 1 g (29% reduction) of salt in bread. Data from two different surveys regarding blood pressure and salt intake was gathered. We estimated the decrease in blood pressure with respect to current average values according to sex, age, education and region.

Results:

It is expected that a reduction of 29% in salt intake through bread contributes to a general decrease in systolic pressure for normotensive people (from 120.4mmHg to 120.0mmHg, p = 0.85) and hypertensive people (from 151.0mmHg to 150.1mmHg, p = 0.68), although not statistically significant. Older hypertensive individuals (65 to 75 years) are the group with the largest benefit (152.8mmHg to 152.0mmHg) but no statistical difference was found. Disaggregation by sex, region and education also didn't show any statistical difference.

Lessons:

The impact in blood pressure from a 29% reduction in salt intake from bread seems very small. We found no statistical significance between the current and expected values in blood pressure either for total or group stratification. The absence of statistical effect might be due to sample size as our sources only allowed us to work with aggregated data.

Key messages:

- Quality and access to data is needed to assess impact of policies.
- to increase effects in blood pressure either salt reduction from bread must be larger or a wider range of products should be considered.

Joint associations of fruit and vegetable consumption and physical activity with mortality risk

Elina Mauramo

E Mauramo[1], J Salmela[1], N Kanerva[1], E Lahelma[1], T Lallukka[1], O Pietiläinen[1], O Rahkonen[1], A Salonsalmi[1], J Lahti[1]
[1]Department of Public Health, University of Helsinki, Helsinki, Finland
Contact: elina.mauramo@helsinki.fi

Background:

Fruit and vegetable consumption (FVC) and leisure-time physical activity (LTPA) are associated with better health outcomes but less is known about their joint associations with the risk of mortality. We examined the joint associations of FVC and LTPA with premature mortality among midlife and ageing municipal employees, adjusting for key covariates.

Methods:

Survey data collected in 2000–2002 among 40–60-year-old employees of the City of Helsinki, Finland, were linked with complete register data on mortality from Statistics Finland (4961 women, 1373 men; response rate 67%; written consent for register linkages 74%). FVC was dichotomised into daily or non-daily, and LTPA into high (>14 MET-hours/week including vigorous exercise) or low. Covariates included age, sex, marital status, socioeconomic position, binge drinking, smoking and self-rated health. Cox regression models were fitted. The follow-up continued until the event of death or the end of 2015.

Results:

A total of 281 deaths occurred during the follow-up. The mortality rate was 7.1% in men and 3.7% in women. A gender interaction was found, showing differing associations for women and men. Men with both daily FVC and high LTPA had the lowest mortality risk (HR 0.19, 95% CI 0.06-0.63) after adjusting for covariates. Men with high LTPA and non-daily FVC also had a lower mortality risk (HR 0.51, 95% CI 0.29-0.90) compared to those with non-daily FVC and low LTPA. Women with daily FVC and high LTPA had a lower mortality risk initially, but after adjusting for covariates no statistically significant associations were observed.

Conclusions:

The joint associations of FVC and LTPA with premature mortality differed between women and men. This could be related to gender differences in e.g. the causes of death, and further studies are needed to clarify this. Increasing FVC and LTPA might prevent premature mortality among men.

Key messages:

- Fruit and vegetable consumption jointly with physical activity decreased the risk of premature mortality among men only.
- Further studies are needed to clarify the gender difference which could be related to for example death causes.

Medical costs associated with childhood maltreatment history among Japanese older people

Aya Isumi

A Isumi[1,2], T Fujiwara[1], H Kato[2,3], T Tsuji[4], D Takagi[5], N Kondo[5], K Kondo[4,6]
[1]Department of Global Health Promotion, Tokyo Medical and Dental University, Tokyo, Japan
[2]Japan Society for the Promotion of Science, Tokyo, Japan
[3]Graduate School of Business Administration, Keio University, Tokyo, Japan
[4]Center for Preventive Medical Sciences, Chiba University, Chiba, Japan
[5]Department of Health and Social Behavior, The University of Tokyo, Tokyo, Japan
[6]Center for Gerontology and Social Science, National Center for Geriatrics and Gerontology, Aichi, Japan
Contact: isumi.hlth@tmd.ac.jp

Background:

Childhood maltreatment can have a significant impact on health across the life course, but its impact on health care costs in later life is unknown in Japan. This study aims to assess additional medical costs of Japanese older people with childhood maltreatment history.

Methods:

Data from the Japan Gerontological Evaluation Study (JAGES) 2013, a population-based cohort of independent people aged 65 years or older across Japan were used and linked uniquely with the database of health insurance claims for residents of a city with more than 1.5 million citizens, aged 75 years or younger (N = 978). Average annual medical costs for April 2012 and March 2013 and April 2013 and March 2014 were calculated and compared between those who experienced childhood maltreatment and those who did not, using generalized linear models.

Results:

4.5% of our sample witnessed their father physically abusing their mother, 1.9% were physically abused, 10.6% were emotionally neglected, and 5.7% were emotionally abused in their childhood. Average medical costs of those with any childhood maltreatment (N = 176, 18.0% of the sample) were significantly higher than those without maltreatment (549,468JPY vs. 413,013JPY (1USD is equivalent to 110JPY); p = 0.007). When examining the effect of each type of maltreatment, average costs of those with emotional neglect were higher than the counterpart (573,481JPY vs. 412,082JPY; p = 0.008). Average costs of those who experienced physical abuse were also higher than those who did not (726,254JPY vs 431,106JPY; p = 0.035). The effect of any childhood maltreatment remained statistically significant after older adults' age and gender were controlled (p = 0.03).

Conclusions:

Our findings suggest that childhood maltreatment is strongly associated with additional medical costs among older Japanese. If it was truly causal, it can be estimated that additional medical costs associated with childhood maltreatment can be more than 333 billion JPY per year nationwide.

Key messages:

- Average annual medical costs of older adults with any childhood maltreatment history were significantly 116,098 JPY greater than those with no maltreatment history.
- As for each type of childhood maltreatment, emotional neglect tends to increase medical costs in late adulthood.

Body size, Mental health and Inequalities: The burden of obesity in South Africa

Ilona Koupil

I Koupil[1,2], *J Mchiza*[3], *MZ Hossin*[2], *W Parker*[4]
[1]Department of Public Health Sciences, Stockholm University, Stockholm, Sweden
[2]Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden
[3]School of Public Health, University of the Western Cape, Bellville, South Africa
[4]Population Health, Health Systems and Innovation, Human Sciences Research Council, Cape Town, South Africa
Contact: ilona.koupil@chess.su.se

Background:

Given the substantial burden of obesity in South Africa, it is important to understand how specific aspects of socio-economic position influence the risk of unhealthy weight in different gender or ethnic groups.

Methods:

We investigated body mass index distributions among subjects aged 15+ years from the South African National Health and Nutrition Examination Survey. Determinants of underweight, overweight and obesity were studied in 1655 (73%) men and 3104 (74%) women who had data available on social and mental health characteristics. Logistic and multinomial regressions were used to study associations with weight categories.

Results:

Less than half of the subjects had healthy weight, 22% were overweight and 29% were obese. The proportion of healthy weight decreased and the risk of obesity increased with age up to 65 years. African women had a particularly high risk of overweight and obesity compared to men (age adjusted OR 4.65, 95% CI 3.94-5.50). The effect of gender was smaller in non-Africans (age adjusted OR 3.02, 95% CI 2.41-3.79; test for statistical interaction $p = 0.004$). Employment and higher education were associated with higher risk of overweight and obesity and a lower risk of underweight. Married subjects were at a higher risk of overweight and obesity. In men, higher income was associated with overweight and obesity. We found weak evidence of poor mental health being associated with unhealthy BMI.

Conclusions:

There are social gradients and gender and ethnic differences in how underweight, overweight and obesity are distributed in the South African population. A high prevalence of obesity among women and positive associations of education, employment and income with overweight and obesity call for investments into health literacy. Action is also needed to prevent undernutrition among socially disadvantaged groups, and men in particular.

Key messages:

- There are strong social gradients and important gender and ethnic differences in how underweight, overweight and obesity are distributed in the South African population.
- High prevalence of obesity in women and positive associations of socioeconomic position with obesity indicate poor health literacy. Undernutrition needs to be reduced among socially disadvantaged.

Trends of sarcopenia and physical activity in elderly Koreans using KNHANES 2007-2017

Hyungsoon Ahn

HS Ahn[1], *BW Kim*[1], *Y Park*[1], *Moran Ki*[1]
[1]Cancer Control and Population Health, Graduate School of Cancer Science and Policy, National Cancer Center Korea, Goyang-si, Gyeonggi-do, South Korea
Contact: 1906101@ncc.re.kr

Background:

Sarcopenia is one of risk factors for prevalence of chronic diseases which is associated with aging. Distribution of sarcopenia in Korea is important because Korea is one of the most rapid countries in population aging. This study aimed to understand trends in PA in elderly Koreans (≥65 years of age) and identify the proportion of sarcopenia in elderly Koreans based on a reference cutoff value of handgrip strength (28.6kg for men and 16.4kg for women).

Methods:

This study was performed using data from Korea National Health and Nutrition Examination Survey (KNHANES) between 2007-2017. Physical activity on walking (2007-2017), aerobic exercise (2014-2017), and muscle strength (2007-2017) were analyzed to understand trends of physical activity participation in elderly Koreans. Furthermore, using handgrip strength data from KNHANES (2014-2017), the study examined how sarcopenia has distributed in elderly in Korea.

Results:

The proportion of elderly Koreans engaged in walking decreased from 46.8% (age standardized) in 2007 to 35.7% in 2017, and the proportion of elderly Koreans engaged in aerobic exercise decreased 41.1% in 2014 to 29.4% in 2017. Even though, the proportion of elderly Koreans engaged in muscle strength increased from 11.6% in 2007 to 17.5% in 2017, the proportion of sarcopenia in elderly men increased from 22.6% in 2014 to 29.3% in 2017 and the proportion of sarcopenia in elderly women increased from 19.3% in 2014 to 30.1% in 2017.

Conclusions:

During the past 10 years, the participation in muscle strength has increased, while the participation in walking and aerobic exercise has decreased in elderly Koreans. Nevertheless, the proportion of sarcopenia in elderly Koreans has increased. This analysis provides evidence of necessity of public health efforts to implement sarcopenia reduction interventions and examine the correlation between sarcopenia and physical activity pattern in elderly Koreans.

Key messages:

- Although the participation of physical activity has decreased, the participation of muscle strength has increased in elderly Koreans (≥65 years of age).
- The increased proportion of sarcopenia in elderly Koreans showed the necessity of new public health intervention to reduce sarcopenia in spite of growing trends of muscle strength in elderly Koreans.

The Trends of Underweight in South Korean between 1998 and 2015

Kyungjin Lee

Kyung Jin Lee[1], *Juwon Lim*[2]
[1]Department of Family Medicine, Seoul Asan Medical Center, Seoul, South Korea
[2]Department of International Healthcare Center, Seoul National University Hospital, Seoul, South Korea
Contact: to7starz@naver.com

Background:

Underweight is associated with increased mortality, relative to the normal weight category. The importance of managing underweight patients has not yet been recognized seriously in South Korea, and little information is available on the prevalence of underweight and its associated risk factors. This study aims to investigate changes in the prevalence of underweight by gender and age and analyze its trend.

Methods:

Data were obtained from individuals aged >20 years, from the Korean National Health and Nutrition Examination Survey between 1998 and 2015. The subjects of this study included 134,613 adults (male, 61,152; female, 73,461). The prevalence of underweight was determined as defined by the Asia-Pacific Perspective, and socioeconomic factors associated with a predisposition to underweight were analyzed using the chi-squared test and multiple logistic regression analysis.

Results:

Among Korean adults, the age-adjusted prevalence of underweight (body mass index <18.5 kg/m2) was 3.1% in men and 6.3% in women. Overall, a U-shaped relationship was established between the prevalence of underweight by gender and age. There was no significant difference in socioeconomic factors related to the prevalence of underweight in men and women in their twenties. The prevalence of underweight in women aged 20-59 years showed an increasing trend (P for trends <0.05).

Conclusions:

In individuals aged 20-29 years, the prevalence of being underweight was higher in women than in men. Recently, there has been an increasing trend in the prevalence of underweight young women of reproductive age. This requires national public health attention.

Key messages:

- Underweight in old age and young age requires nation wide public health attention.
- Especially thinness in young women in reproductive age must be considered as global health issue.

Evaluation of Malnutrition and Depression in Elderly People: An Epidemiological Study in Turkey

Sevil Aydoğan

S Aydoğan[1], A Ünsal[1], D Arslantaş[1]
[1]Department of Public Health, Eskişehir Osmangazi University Medicine Faculty, Eskişehir, Turkey
Contact: aydogan.sevil@gmail.com

Background:

Malnutrition is an important cause of morbidity and mortality. Malnutrition increases the number of hospitalizations and prolongs the length of hospitalization by disrupting organ functions, increasing the number and severity of infections and delaying wound healing. The aim of this study was to determine the frequency of suspected malnutrition in the elderly, to examine some related variables and to evaluate the depression.

Methods:

The study is a cross-sectional study conducted between March-April 2019 in individuals aged 60 years and older living in Sivrihisar. Sample size was calculated as 579. Cluster sampling method used. Data was collected by door to door in 4 neighborhoods determined by randomly. Mini Nutritional Assessment Test-Short Form (for malnutrition), Katz Daily Living Activities Scale (for dependency) and Geriatric Depression Scale-Short Form (for depression) were used. Chi-square test, Mann Whitney U test and logistic regression analysis were used for the analyzes.

Results:

The study group consisted of 220 (38%) women and 359 (62%) men. The mean age was 68.9±6.4 (ranged 60-93). Frequency of suspected malnutrition was 25% (n = 145). Being 80 years of age or older (OR:3.24, CI:1.53-6.85), having a primary and lower education level (OR:2.54, CI:1.32-4.90), history of chronic illness (OR:2.34, CI:1.33-4.03), using dentures (OR:1.62, CI:1.03-2.55) and suspected depression (OR:4.97, CI:3.17-7.78) are important risk factors for malnutrition. Those with suspicion of malnutrition had lower scores on DLA (z = 8.982;p = 0.001).

Conclusions:

Malnutrition was found to be an important health problem for the elderly. The frequency of suspected malnutrition is higher in individuals with depression. Those with suspected malnutrition have higher level of dependency. In order to reduce the frequency of malnutrition, it may be beneficial to increase the awareness of the elderly and caregivers and to give importance to the elderly nutrition of primary health care providers.

Key messages:

- Depression is an important risk factor for malnutrition.
- Malnutrition increases the dependence of the individual on daily activities.

2.S. Child and adolescent health

The Evaluation of Stigmatization and Related Factors in Students of Health-Related Faculties

Sevil Aydoğan

S Çalışkan Pala[1], EE Öcal[1], S Aydoğan[1], Z Demirtaş[1], E Atay[1], D Oktar[1], A Mutlu[1], MF Önsüz[1], S Metintaş[1]
[1]Department of Public Health, Eskişehir Osmangazi University Medicine Faculty, Eskişehir, Turkey
Contact: aydogan.sevil@gmail.com

Background:

Individuals with disabilities are the people in which health inequalities are mostly experienced. Stigmatization of disabled people reduces their participation in society and causes insufficient health care. Not stigmatize disabled people by health care providers is important to eliminate this insufficiency. The aim of the study was to determine the stigmatization level and communication related factors of students educated in health-related faculties.

Methods:

This cross-sectional study conducted in 873 university students who educated in health-related faculties. The level of stigmatization was measured with Disability Stigma Scale(DSS) including the items used in study performed by Mclaughlin et al. The questionnaire consists of sociodemographics and items of contact with disabled persons(CDP) scale.

Results:

The mean age of study group was 20.19 ± 1.63, and the 71% were female. The prevelance of stigmatization for disabled people was 33.7%. Of 62.3% study group scored below the mean score from CDP scale. In univariate analysis, the prevelance of stigma was higher in the male group (p < 0.001), low education level group (p < 0.005) and low communication level group (p = 0.020). In multivariate analysis, the risk of stigma for disabled people increases 2.1 times (OR;95% CI, 1.53-2.85) in male group, reduces 0.70 times (0.53-0.93) in high education level parents group and reduces 0.98 times (0.97-0.99) in high communication level group.

Conclusions:

It was concluded that stigmatization against disabled people is very important issue for investigation and intervention in males, parents with low education groups and low communication level groups.

Key messages:

- Communication with disabled people is a very important factor that could be modified and improved for reducing the stigmatization about disabled people.
- Intervention studies are needed for reducing stigmatization against disabled people in students educated in health-related faculties to eliminate inequalities in health.

Socioeconomic disparities in diabetes prevalence and quality of care among Israeli children

Ronit Calderon-Margalit

Y Loewenberg Weisband[1,2], R Calderon-Margalit[1,2], Y Wolff-Sagy[1,2], M Krieger[1,2], W Abu-Ahmed[1,2], A Ben-Yehuda[3,2], E Horwitz[4,2], O Manor[1,2]
[1]Braun School of Public Health and Community Medicine, The Hebrew University of Jerusalem, Jerusalem, Israel

[2]Program Directorate, National Program for Quality Indicators in Community Healthcare in Israel, Jerusalem, Israel
[3]Department of Internal Medicine, Hadassah-Hebrew University Medical Center, Jerusalem, Israel
[4]Pharmacy Division, Hadassah-Hebrew University Medical Center, Jerusalem, Israel
Contact: ronitcm@gmail.com

Background:

Despite Israel's universal health coverage, disparities in health services provision may still exist. We aimed to assess socioeconomic disparities in diabetes prevalence and quality of care among Israeli children, and to assess trends in these over time.

Methods:

Repeated cross-sectional analyses in the setting of the National Program for Quality Indicators in Community Healthcare that receives data based on electronic medical records from Israel's four health maintenance organizations. The study population included all Israeli children aged 2-19 years in 2011-2017 (for 2017: N = 2,364,374, including 2,914 with diabetes). Socioeconomic position (SEP) was measured using Central Bureau of Statistics data further updated by a private company (Points Business Mapping Ltd), and grouped into 4 categories, ranging from 1 (lowest) to 4 (highest). Using logistic regression, we assessed the association of SEP with diabetes prevalence, diabetes clinic visits, hemoglobin A1C (HbA1C) testing, and poor glycemic control (HbA1C> 9%), and assessed whether these changed over time. Models were adjusted for age, and sex.

Results:

Diabetes prevalence increased with age and SEP. SEP was positively associated with visiting a specialized diabetes clinic (OR SEP 4 vs. 1 2.53, 95% CI 1.72 - 3.70). Odds of HbA1C testing and odds of poor glycemic control were negatively associated with SEP (OR SEP 4 vs. 1: 0.54, 95% CI 0.40 - 0.72 and OR SEP 4 vs. 1: 0.25, 95% CI 0.18 - 0.34 respectively). Disparities were especially apparent among children aged 2-9 (4.6% poor glycemic control in SEP 4 vs. 40.8% in SEP 1). Poor glycemic control decreased over time, from 44.0% in 2011 to 34.8% in 2017.

Conclusions:

While poor glycemic control rates among children have improved, significant socioeconomic gaps remain. It is eminent to study the causes of these disparities and develop policies to improve care provided to children in the lower SEP levels, to promote health equity.

Key messages:

- Major socioeconomic inequalities in the control of diabetes among children in Israel remain despite universal health care coverage.
- The rate of uncontrolled diabetes among Israeli children has improved over time.

Family environment risk factors for overweight in childhood

Vesselka Duleva

V Duleva[1], E Chikova-Iscener[1], L Rangelova[1], Pl Dimitrov[2]
[1]Food and Nutrition, National Centre of Public Health and Analyses, Sofia, Bulgaria
[2]Health Promotion and Disease Prevention, National Centre of Public Health and Analyses, Sofia, Bulgaria
Contact: v.duleva@ncpha.government.bg

Background:

One of the current public health problems in Bulgaria is the high prevalence of overweight and obesity in childhood. The family environment affects many aspects of children's health and well-being. The unfavourable socio-economic characteristics of the family environment might be a risk for overweight and obesity in childhood.

Methods:

A national representative survey was conducted in Bulgaria in 2016 as part of the WHO European Childhood Obesity Surveillance Initiative (COSI). 3379 schoolchildren were recruited. The average age of the sample was 7.7 years, equally distributed by gender - girls 50.11% (n = 1693) and boys 49.89% (n = 1686). The data from the filled in Family form was analysed with SPSS using descriptive statistical methods.

Results:

The study identified the following risk factors of the family environment for the development of overweight in childhood: the proportion of parents with elementary or primary education was significant - about a quarter, nearly one third of the surveyed households were experiencing financial difficulties, 14.1% of the women and 11.6% of the men were unemployed in the last 1 year. There was a high incidence of co-morbidity among family members: hypertension - 27.7%, diabetes mellitus - 14.4% and hypercholesterolemia - 13.6%. Among the surveyed parents 28.4% of the women and 68% of the men were overweight. Only 13.5% of the parents estimated the weight status of their child as overweight (with objectively measured overweight among 29.2% of the recruited children). A significant proportion of the children were not breastfed (17.3%) or the duration of exclusive breastfeeding was not optimal for 67.8% of the exclusively breastfed children.

Conclusions:

Identifying family risk factors associated with overweight in childhood is important for the public health and provides opportunities to develop policies for improvement of the nutritional and health status of children.

Key messages:

- To tackle the childhood obesity epidemic the family risk factors should be addressed.
- The awareness of the children and parents should be raised through targeted information materials and campaigns.

Factors associated with self- and other-directed aggression in Slovak adolescents

Anna Janovska

A Janovska[1], B Gajdosova[1], O Kalina[1]
[1]Department of Educational Psychology and Psychology of Healt, P.J.Safarik University, Kosice, Slovakia
Contact: anna.janovska@upjs.sk

Background:

We investigated differences in intrapersonal and interpersonal characteristics of adolescents with and without reported aggressive behaviours (AB). We distinguished two types of intrapersonal factors (self-esteem (SE), self-control (SC)) and three types of interpersonal factors (prosocial peers (PP), supportive relationships at home (SRH), supportive relationships at school (SRS)). We separately examined self-directed aggressive behaviours (self-destructive thoughts, self-destructive behaviour) and other-directed aggressive behaviours (using vulgar words, fighting, physical harm, intimidation, mockery of classmates).

Methods:

A representative sample of 1101 adolescents (50.1% female, mean age of 13.5 years) was collected from primary schools in Slovakia. The respondents completed the SE Scale, the SC Scale, the Resilience and Youth Development scale and they were also asked about the frequency of AB. In each form of AB (self- and other-directed) two groups were created: those who reported some AB and those who did not report any AB. Descriptive statistics and nonparametric tests were used for the data analysis.

Results:

Almost 75% of the adolescents reported some AB towards others and 41% reported self-harming thoughts or behaviours. Statistically significant differences were observed for both self-directed AB (SE: $p<.001$, SC: $p<.001$, PP: $p<.001$, SRH: $p = .013$, SRS: $p<.001$) and other-directed AB (SE: $p = .034$, SC: $p<.001$, PP: $p<.001$, SRH: $p = .039$, SRS: $p = .016$). In all cases adolescents who reported AB typically had a lower level of intrapersonal and interpersonal variables compared to those who did not report AB.

Conclusions:

The study contributed to the understanding of factors linked to aggressive behaviour of adolescents and confirmed the associations with self-esteem, self-control, supportive relationships at home and at school and having prosocial peers.

Key messages:

- Aggressive behaviour of adolescents can be linked to interpersonal and intrapersonal relationships.
- The above holds for both self- and other-directed aggression.

Suicidal ideation among Tunisian adolescents and the association with adverse life experiences

Jihene Sahli

J Sahli[1], *J Mannai*[2], *C Zedini*[1], *M Limam*[1], *L Merzougui*[3], *T Ajmi*[1], *A Mtiraoui*[1], *M Mellouli*[1], *M El Ghardallou*[1]
[1]Department of Familial and Community Medicine, University of Sousse, Faculty of Medicine of Sousse, Research Laboratory ''LR12ES03'', Sousse, Tunisia
[2]Department of Psychiatry, University of Sousse, Faculty of Medicine of Sousse, University Hospital Ibn El Jazzar Kairouan, Sousse, Tunisia
[3]Department of Hospital Hygiene, University of Sousse, Faculty of Medicine of Sousse, University Hospital Ibn El Jazzar Kairouan, Sousse, Tunisia
Contact: dr-jihene19@hotmail.com

Background:

Youth suicidality is a significant public health problem. Understanding the factors leading to suicide is essential to implement effective preventive efforts. In this context, this study was conducted to assess the link between suicidal ideation and adverse life experiences among Tunisian school aged youth.

Methods:

A cross-sectional survey was conducted among a sample of 2020 secondary school adolescents in 2016. An anonymous self-administered questionnaire was used to collect data. The adverse life events measured were: domestic violence, parental divorce, physical aggression, sexual abuse and a familial antecedent of suicide.

Results:

Overall, 17.0% (95% CI [15.3%-18.6%]) reported having suicide ideation during the past 12 months with no gender difference (16.3% among girls and 17.3% among boys, p = 0.62). Among the participants, 26.7% experienced at least one adverse life experience. Those who reported domestic violence (Odds Ratio = 8.93; 95% CI = 6.84–11.66), parental divorce (Odds Ratio = 3.02; 95% CI = 1.57–5.79), physical aggression (Odds Ratio = 6.97; 95% CI = 5.14–9.46), sexual abuse (Odds Ratio = 8.69; 95% CI = 3.94–19.15), familial antecedent of suicide (Odds Ratio = 8.17; 95% CI = 5.75–11.60) were associated with increased odds of suicide ideation.

Conclusions:

The prevalence of suicidal ideation observed in the survey area was relatively high and associated with all the measured life adverse events. These factors should be included in a suicide screening tool to be integrated in a suicide prevention program.

Key messages:

- Suicidal ideation among adolescents was associated with all the measured life adverse events.
- Identifying adolescents at higher risk of suicide and help them to cope with their adverse experiences could be effective to prevent taking action to attempt suicide.

Mood disorders with onset in early adulthood and socio-economic outcomes over the long run

Christian Hakulinen

C Hakulinen[1], *KL Musliner*[2], *E Agerbo*[2]
[1]Department of Psychology and Logopedics, University of Helsinki, Helsinki, Finland
[2]National Centre for Register-Based Research, Aarhus University, Aarhus, Denmark
Contact: christian.hakulinen@helsinki.fi

Background:

Mood disorders have been associated with poor socioeconomic outcomes, but there is a lack of large-scale population-based studies on the topic. We examined associations between bipolar disorder and depression with an onset between ages 15 and 25, and subsequent socio-economic outcomes (employment, income and educational attainment) using Danish registry data.

Methods:

All individuals (n = 2 390 127; 49% women) born in Denmark between 1955 and 1990, who were alive at their 25th birthday were included. Employment status, wage or self-employment earnings, and educational attainment were assessed annually from the age of 25 to 58 (years 1980 to 2015). Mood disorder diagnosis was obtained from the Danish Psychiatric Central Register. The associations were examined using logistic regression analyses.

Results:

At the age of 30, 46% of individuals with bipolar disorder and 35% of individuals with depression were not employed, and 52% of individuals diagnosed with bipolar disorder and 42% of individuals with depression did not have any secondary or post-secondary education. Bipolar disorder and depression were associated with increased and increasing risk (at age 30: bipolar disorder, OR 7.21, 95% CI 6.54 to 7.96; depression, OR 4.07, 95% CI 3.93 to 4.22) of not being employed over the follow-up. Similarly, both bipolar disorder and depression were associated with increased risk of not completing secondary or post-secondary education (at the age of 30, bipolar disorder: OR 3.21, 95% CI 2.92 to 3.54; depression: OR 2.81, 95% CI 2.71 to 2.91), but this difference become smaller over the follow-up. An individual with bipolar disorder or depression earned around 36% and 51%, respectively, of the earnings earned by an individual without mood disorders.

Conclusions:

Mood disorders diagnosed in early adulthood are associated with lasting poor socioeconomic outcomes over the long run.

Key messages:

- Early onset mood disorders are associated with consistently, and in some cases increasingly, poorer socioeconomic outcomes over time.
- An individual with early onset bipolar disorder or depression earned around third and half, respectively, of the earnings earned by an individual without early onset mood disorders.

Intrapersonal/interpersonal factors related to alcohol use and smoking cigarettes among juveniles

Beata Gajdosova

B Gajdosova[1], *O Orosova*[1], *A Janovska*[1]
[1]Department of Educational Psychology and Health Psychology, Košice, Slovakia
Contact: beata.gajdosova1@upjs.sk

Background:

While there is consistent evidence that an early initiation of smoking and alcohol consumption is associated with a whole range of future negative outcomes, relatively little attention has been directed at a specific population of very young adolescents (10-12 years old). This study aimed to explore the relationships between alcohol use, smoking and intra/interpersonal factors among primary school pupils.

Methods:

In this study (APVV-0253-11, APVV-15-0662) a representative sample of 572 early adolescents from a stratified random sample of 12 primary Slovak schools (50.1% boys, Mean age = 12.49; SD = 0.59) was used. The respondents indicated their lifetime prevalence of smoking SM and alcohol use AU (dichotomized: 0-not used, 1-used) which was used as an outcome variable. Expectations of the effect of smoking and alcohol use (positive or negative), self-control and cigarette and alcohol refusal were used as the independent variables. Binary logistic regressions were performed and carried out separately for boys and girls.

Results:

All 4 models were statistically significant for males (AU = 15.318, $p < 0.01$, 9.8%, SM = 17.807, $p < 0.01$, 9.8%) and also for females (AU = 25.204, $p < 0.001$, 16%, SM = 47.05, $p < 0.001$, 24.7%). The models showed that for boys there were significant associations between smoking refusal and smoking cigarettes 95%CI = 0.845-0.97 and alcohol refusal and alcohol prevalence 95%CI = 0.78-0.95. For girls, significant associations were found between smoking refusal and smoking cigarettes 95%CI = 0.75-0.92, alcohol refusal and alcohol prevalence 95%CI = 0.72-0.95, positive expectations 95%CI = 1.04-1.20, negative expectations 95%CI = 0.78-0.94, self-control 95%CI = 0.91-1.00 and alcohol prevalence.

Conclusions:

This study supports the importance of the specific role of refusal skills for both genders as well as the importance of the role of expectations and self-control with respect to gender differences.

Key messages:

- Implementation of the findings regarding the importance of specific refusal skills towards alcohol use and smoking among both genders might be important for effective targeting of prevention programs.
- The results show a similar trend regarding smoking which was observed among both genders but this was not seen in alcohol use.

What should parents do to emphasise their disapproval of adolescents’ substance use?

Maria Bacikova-Sleskova

M Bacikova-Sleskova[1], L Hricová[1], O Kalina[1], J Benka[1]
[1]Department of Educational Psychology and Health Psychology, University of PJ Safarik, Kosice, Slovakia
Contact: maria.bacikova@upjs.sk

Background:

Previous research has shown that one of the strongest predictor of smoking and alcohol consumption in early adolescence is perceived parental approval of such behaviour. The aim of the present study is to explore which parenting practices predict the probability of perceiving parental disapproval of smoking and alcohol consumption in adolescence.

Methods:

A representative sample of 1133 early adolescents (mean age = 12.9, SD 0.77) filled in questionnaires including sociodemographic characteristics (3 items), perceived parental risk behaviour (alcohol consumption at least once a week, drunkenness once a month and daily smoking); substance specific conversations with parents (1 item); both emotional and controlling aspects of parenting (6 items), and perceived parental disapproval of adolescents’ smoking and alcohol consumption as dependent variables. Logistic regression was used to analyse the data.

Results:

The most important predictor of perceived parental disapproval of alcohol use was behavioural control (setting rules) (OR 2.34), followed by parental non-drinking (OR 1.81) and alcohol specific communication (OR 1.28). Regarding smoking disapproval, the significant predictors were parental non-smoking (OR 1.92); behavioural control (OR 1.79); time spent with a child (OR 1.44) and lower psychological control (guild induction, pressuring, manipulation) (OR 0.69).

Conclusions:

Decreasing adolescents’ substance use via increasing their perceived parental disapproval of such behaviour seems to be substance specific. The most salient strategy both for smoking and drinking seems to be the use of behavioural control characterized by clear rules setting and lack of parental own substance use.

Key messages:

- Decreasing adolescents’ substance use via increasing their perceived parental disapproval of such behaviour seems to be substance specific.
- The most salient strategy to increase perceived parental disapproval of smoking and alcohol consumption seems to be the use of behavioural control characterized by clear rules setting.

Adolescent tooth brushing frequency evolution (2006-2014), risk factors and causality hypothesis

Gabriel Fernandez de Grado

G Fernandez de Grado[1,2,4], D Offner[1,2], E Godeau[5], C Nabet[3,4], AM Musset[1,2]
[1]Faculté de Chirurgie Dentaire de Strasbourg, Strasbourg, France
[2]UMR 1260, INSERM, Strasbourg, France
[3]Faculté de Chirurgie Dentaire de Toulouse, Toulouse, France
[4]UMR 1027, INSERM, Toulouse, France
[5]EHESP School of Public Health, Rennes, France
Contact: gabfdg@free.fr

Objectives:

To analyze the evolution of tooth brushing frequency (TBF) as well as the impact of socio-economic status and health behaviors between 2006, 2010 and 2014 among adolescents from the French Health Behavior in School-aged Children (HBSC) cross-sectional studies.

Methods:

We included 18727 adolescents aged 11, 13 or 15 years old (y/o). The relationship between TBF and variables such as eating habits, health and socio-economic status markers as well as their evolution over the 3 studies were analyzed using logistic regression. We used directed acyclic graphs (DAGs) to represent the potential chain of causality between TBF, its associated factors, as well as latent variables such as the risk for oral diseases.

Results:

Proportion of adolescents brushing twice a day increased from 68.8% in 2006 to 70.8% in 2010 and 78.8% in 2014 ($p < 0.0001$). Notable predictors ($p < 0.0001$) were being a girl (adjusted Odd Ratio = 1.5) and even more an older girl (aOR 1.5 for 15y/o vs 11 y/o girls), having breakfast and fruits daily (aOR 1.4 and aOR 1.6), excellent perceived health (aOR 1.2), obesity or overweight (aOR 0.6), being bullied at school (aOR 0.8) and perceived family wealth (aOR 1.4 for High vs Low). Impacts of these predictors were stable over the 3 studies. DAGs highlighted the fact that a low TBF and its associated risk factors described a high-risk population for poor oral and global health. Variables at the origin of those risks seemed to be age, sex, familial environment, socio-economic environment and education.

Conclusions:

TBF among French adolescents improved from 2006 to 2014. This may be linked with global prevention programs developed during this time period. These programs should be associated with more specific ones targeted towards and adapted to disadvantaged populations to diminish inequalities. The use of DAGs is a powerful tool to identify the origin of those inequalities as well as the right factors to target in order to achieve efficient prevention.

Key messages:

- Global and specific prevention programs should be associated to allow a global improvement in tooth brushing as well as a diminution of inequalities.
- Use of specific statistical tools can help identify specific trends in health behaviors and alterable risk factors.

Adolescent suicide behaviour profiles: comparing unplanned attempts, planned attempts and ideation

Claire van Duin

C van Duin[1], C Catunda[1], A Heinz[1], H Willems[1]
[1]Inside Research Unit, University of Luxembourg, Esch-sur-Alzette, Luxembourg
Contact: claire.vanduin@uni.lu

Background:

Suicide is the second leading cause of death for young people worldwide. A significant amount of suicide attempts is known to be unplanned, but research on unplanned attempts among adolescents is limited. As knowledge on the profile of unplanned suicide attempts is crucial for effective prevention efforts, this study aims to characterize and compare three suicide behaviour profiles among adolescents: planned attempts, unplanned attempts and ideation without attempt.

Methods:

Data from the 2014 Luxembourgish Health Behaviour in School-aged Children study was used. 879 adolescents aged 12 to 18 years old are included in this study. Data was gathered using paper questionnaires. ANOVAs with Games-Howell post-hoc tests were conducted for 18 independent variables, using the suicide behaviour variable as the dependent variable.

Results:

Unplanned attempters report higher levels of parental and classmate support ($p < 0.01$), fewer health complaints ($p < 0.001$), higher life satisfaction ($p < 0.01$) and a more positive body image ($p < 0.01$) than planned attempters and ideators. Unplanned and planned attempters are younger than ideators ($p < 0.01$) and report more substance use and physical fighting than ideators ($p < 0.01$).

Conclusions:

Unplanned attempters report better health (behaviour) and more social support than planned attempters and ideators. Unplanned attempters and planned attempters have higher levels of risk behaviour than ideators. Prevention efforts should be mindful of similarities and differences between the behaviours, and identify and address at risk adolescents accordingly.

Key messages:

- Unplanned attempters have better health (behaviour) and more social support than planned attempters and ideators.
- Results are incorporated in the Luxembourgish national plan for suicide prevention.

Association between positive mental health and family background among young people in Finland

Kaija Appelqvist-Schmidlechner

K Appelqvist-Schmidlechner[1], N Tamminen[1], P Solin[1]
[1]Mental Health, National Institute for Health and Welfare, Helsinki, Finland
Contact: kaija.appelqvist@thl.fi

Background:

Positive mental health (PMH) is an important construct for understanding the full continuum of mental health. The aim of this study was to examine the association of family background with the level of PMH among adolescents and young adults in Finland.

Methods:

Data from population-based Finnish School Health Promotion Study targeted at year 8. and 9. students of comprehensive school and year 1. and 2. students of upper secondary school and vocational schools was used (n = 134684) for the study. PMH was measured with short Warwick-Edinburgh-Mental-Wellbeing-Scale (SWEMWBS) and examined on a continuum from languishing (low level of positive mental health) to moderate to flourishing mental health (high level of positive mental health). Associations between flourishing/languishing mental health and family background variables were analysed with logistic regression analysis, school level and gender were adjusted.

Results:

Flourishing mental health was associated with intact family background, higher education of parents and better financial situation of family. In contrast, languishing was associated with non-intact family conditions (single parent family, parents divorced, stepfamily) and parents' unemployment, lower level of education and financial problems.

Conclusions:

Family structure and socioeconomic status of parents have an impact on PMH of young people. Young people with non-intact family structure and/or poorer socioeconomic status may lack positive sense of well-being, in other words they have challenges to enjoy their life, to believe in their own abilities, to cope with normal stresses of life, to study productively and to enjoy interacting with others. Targeted interventions and promotive actions should be directed for young people with challenging family conditions in particular.

Key messages:

- Investigating positive mental health (PMH) is essential for understanding the full continuum of mental health.
- Family structure and parents' socioeconomic status have an impact on PMH of young people.

Social capital and students' health: results of the splash study

Insa Backhaus

I Backhaus[1,2], I Kawachi[2], A Ramirez[3], S Jang[4], S Khoo[5], A Al-Shamli[6], L Po-Hsiu[7], E Begotaraj[8], F Fischer[9], G La Torre[1]

[8]Department of Clinical Psychology, Sapienza University, Rome, Italy
[9]Faculty of Health Sciences, Bielefeld University, Bielefeld, Germany
Contact: insa.backhaus@uniroma1.it

Background:

Universities around the world are challenged with rising rates of mental health problems among their students. Cumulative evidence demonstrated that aspects of the social environment, including social capital, play an important role in mental health. This study aimed to determine the prevalence of depressive symptoms among university students from across the globe and to investigate whether social capital was associated with depressive symptoms in university students.

Methods:

A cross-sectional study was conducted in Albania, Brazil, Germany, Italy, Malaysia Oman, South Korea, Switzerland, Taiwan and the USA in 2018/2019. Data were obtained through self-administered questionnaire, including questions on sociodemographic characteristics and depressive symptoms. The BDI-S was used to assess the presence of depressive symptoms. Multilevel analyses were conducted to assess the relationship between social capital and depressive, adjusting for individual covariates (e.g. perceived stress and health behaviours) and country-level characteristics (e.g. democracy type).

Results:

A total 3894 students participated. Out of all participants almost 47% presented clinically relevant depressive symptoms. The prevalence of depressive symptoms was highest among students identifying as other than male or female (48.7%), among students with low socioeconomic status (59.5%) and among students with low levels of cognitive (65.3%) and behavioural social capital (57.0%). Even after adjustment in multilevel logistic regression analyses, depressive symptoms remained significantly associated with low levels of cognitive social capital (OR = 1.49, 95% CI: 1.06 to 2.10) and low level of behavioural social capital (OR = 1.36, 95% CI: 1.08 to 1.71).

Conclusions:

Social capital may play an important role in mental health problems in the university setting. The study identified significant opportunities for future research and health promotion strategies among students.

Key messages:

- Key factors associated with depressive symptoms among university students were low levels of behavioural and cognitive social capital.
- Health promotion programs targeting young persons with depressive symptoms should include effective components of social epidemiology such as social capital.

3.R. Health in education: from childcare to college

Developing a regional strategy to disseminate physical activity promotion in childcare centers

Holger Hassel

M Müller[1], *H Hassel*[1]
[1]Institute of Applied Health Sciences, Coburg University of Applied Sciences and Arts, Coburg, Germany
Contact: iag@hs-coburg.de

Background:

Despite increasing efforts to promote physical activity (PA) in childcare centers, compliance with PA guidelines remains low. QueB is an intervention to promote children's and teachers' capabilities for PA. In QueB1 (2015-2018) a significant increase in children's and teachers' PA (steps/hour) in 12 childcare centers in Germany was achieved. The aim of QueB2 (2018-2021) is to establish strategies to disseminate the intervention in one region and to gain access to hard-to-reach childcare centers.

Methods:

A regional system of multipliers is built up in a participatory process. Structured discussions with stakeholders (childcare consultants, supervisors) are conducted to find out what role they can play in accessing hard-to-reach childcare centers and what support they need for that. In addition, workshops with teachers from different childcare centers are organized to identify their needs and to create a regional peer-to-peer network.

Results:

PA plays only a small role in the work of childcare consultants and supervisors. However, they could give a first impulse as they have regular contact to different childcare centers. Therefore, they need a simple assessment tool that helps them identify childcare centers' need for support and some tailored information material they can share. In addition, the idea of ''PA champions'' was developed: Teachers from childcare centers that have already taken part in QueB will be qualified as peer-to-peer-counselors and invite other teachers for work shadowing or to join the network.

Conclusions:

Strategies to disseminate PA promotion in childcare centers have to involve peers as well as regional multipliers. A simple assessment tool that helps identify childcare centers' needs and an online toolbox with diverse supporting material for multipliers and childcare centers are developed.

Key messages:

- QueB2 will result in regional structures that support the PA promotion of childcare centers.
- The involvement of peers and multipliers is the key to meeting the needs of childcare centers.

'The Pyramid of Success'' the health promotion program for school- children with visual impairment

Magdalena Wrzesinska

M Wrzesinska[1,2], *K Binder*[1], *J Rakoczy*[1], *K Tabała*[1], *A Lipert*[3]
[1]Department of Psychosocial Rehabilitation, Medical University of Lodz, Łódź, Poland
[2]Department of Health Care System Development, Medical University of Lodz, Łódź, Poland
[3]Department of Sport Medicine, Medical University of Lodz, Łódź, Poland
Contact: magdalena.wrzesinska@umed.lodz.pl

Issue/problem:

Young people with visual impairment (VI) are more likely to have low literacy comparing to the rest of population. Additionally, they are at the high risk of obesity what has been attributed to poor food choices or lack of physical activity. Hence, interventions to support their nutrition status are needed.

Description of the problem:

One hundred eighty six students aged 10-18 years ($M = 13.9$; $SD = 2.44$) selected from 6 schools for pupils with VI. An intervention describing healthy lifestyle guidelines was performed. Two innovative tools concerning nutrition guidelines tailored to the needs of people with VI were used during intervention: The Healthy Lifestyle Pyramid (HLP) and the Puzzle Game (PG). Participants were devoted to the Control Group (CG; $N = 94$) where only HLP was used and the Study Group (SG, $N = 92$) who participated in the classes with both tools: HLP and PG. Before and just after intervention a single-choice questionnaire regarding health literacy comprising 15 questions was used to verify the level of required knowledge regarding nutrition.

Results:

There was a significant main effect of using HLP in the CG $F(1. 132) = 14.524$, $p < 0.001$. The main effect of using HLP and PG in the SG was also significant, $F(1. 132) = 6.188$, $p = 0.014$. The actual difference in mean scores between SG and CG was medium. The effect size, calculated using partial eta squared, was .045.

Lessons:

The interventions with tools tailored to the needs of people with VI had positive significant impact on nutrition knowledge. Health promotion activities focusing on the health literacy improvement are more effective when various approaches are used to present information. Future health promotion activities should be adjusted to the needs of different populations to provide an equal access to healthy behaviours and to enhance health literacy.

Key messages:

- Using tools tailored to the needs of people with VI provide an equal access to health promotion.
- Health promotion activities are more effective when range approaches are used to present information.

Food and lifestyle education at primary and secondary school: an Italian project on health promotion

Marco Tarroni

D Messina[1], *M Tarroni*[2], *L Catarsi*[2], *C Balestri*[1], *G Messina*[3,2], *N Nante*[3,2]
[1]Monte dei Paschi Foundation of Siena, Siena, Italy
[2]Post Graduate School of Public Health, Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[3]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
Contact: marco.tarroni@student.unisi.it

Background:

Nutrition and life styles have a crucial role as health determinants. In particular, an intervention on eating habits and physical activity/inactivity does heavily influence obesity and overweight prevention, alongside associated diseases. Preteen and teenage profile is critical for developing the state of health in adulthood, and it is heavily determined by the sociocultural family background. For this reason, school could become an important actor in health promotion, in the form of coordinated and cross-disciplinary courses about food and behaviors. The aim of the study is to verify the effect of an intervention of food education in several schools.

Methods:

This cross-sectional study, originated from the ''sCOOL FOOD'' project of Monte dei Paschi Foundation of Siena, involves schools of southeastern Tuscany, Italy. The project currently engages various classes from primary and secondary schools in which year-round awareness campaigns are conducted. The activities consist in theory classes and workshops held by professionals or teachers of the school previously trained for the purpose. A same questionnaire was administered to families before and after each campaign, exploring eating habits, lifestyle and biometrics. The data analyzed so far date from October 2017 to May 2018. Wilcoxon signed-rank test was performed on the distributions of children BMI classes, defined according to IOTF cutoffs, obtained exclusively from participants who submitted both questionnaires.

Results:

308 paired records of data were collected as mentioned above. We found that, after the campaign, children BMI classes distribution shift towards reduction was statistically significant ($z = -2.053$; $p < 0.05$).

Conclusions:

Since the intervention was able to influence a childhood health determinant, it could be an opportunity to compensate those family dynamics that could lead towards health disadvantages in adulthood.

Key messages:

- A coordinated and cross-disciplinary food and lifestyle year-round education campaign at school can impact on health determinants of children.
- School can correct unfavorable eating and lifestyle behaviors determined by family habits.

Obesity prevention - is school an effective place? A systematic review

Ulla Walter

A Kula[1], S Liersch[1], K Krüger[1], U Walter[1], A Hagen[1]
[1]MHH, Institute for Epidemiology, Social Medicine and Health System Research, Hannover, Germany
Contact: walter.ulla@mh-hannover.de

Background:

Juvenile and childhood obesity or overweight are associated with various secondary diseases and physical limitations, as well as with the effects of discrimination and social exclusion. The early prevention of obesity remains a key area of action worldwide. Schools are considered as a classical setting. The analysis focuses on the effectiveness of interventions, the identification of effective components and conditions as well as barriers. The aim is to provide a differentiated presentation of the current study situation.

Methods:

The systematic literature search in eleven databases included studies in English and German published in 1990 to 2015. A control group and posttest data were obligatory. Evaluated outcome measures must map effects on the prevalence of obesity (e.g., BMI, body fat percentage, waist-to-hip ratio). Included full texts were evaluated with the instrument ROBINS-I. Due to the heterogeneity of studies (especially in terms of design, intervention and outcomes) results were analysed qualitatively.

Results:

48 primary studies were included of which most studies report data on changes in mean BMI over time, and show predominantly (small) effects in favour of the intervention. Almost all identified interventions include behavioral measures, most of them combine the fields of nutrition and physical activity, with behavioral prevention being over-represented in particular in activities addressing nutrition.

Conclusions:

The results allow the conclusion, that school-based measures to prevent obesity are effective in terms of anthropometric outcome measures, but to a limited extent. There is clear evidence that the effects achieved tend to be maintained beyond the intervention. There are also clear indications for the cost-effectiveness of school-based obesity prevention. The studies from this field of research have clearly gained in quality over the years and are now flanked by health economic analyses.

Funded by DIMDI

Key messages:

- School-based measures to prevent obesity are effective in terms of anthropometric outcome measures, but to a limited extent.
- In order to fully realize its potential, school-based measures to prevent obesity should be accompanied by interventions at other levels, like the health-promoting design of living environments.

Effectiveness of a drug use prevention program on alcohol use and drunkenness among schoolchildren

Marcela Štefaňáková

M Štefaňáková[1], M Kulanová-Dobrowolska[2], O Orosová[2], L Abrinková[1]
[1]Department of Ppsychology, PJ Šafárik University in Košice, Košice, Slovakia
[2]Department of Educational Psychology and Psychology of Health, PJ Šafárik University in Košice, Košice, Slovakia
Contact: marcela.stefanakova@upjs.sk

Introduction:

Unplugged is a universal drug prevention program consisting of 12 lessons and intended for primary schools. In the school year 2017/2018, Unplugged was implemented in the Slovak Republic in the 7th grade.

Objective:

To examine the effectiveness of Unplugged on lifetime prevalence of drunkenness and alcohol use during the last 30 days as well as the moderation effect of gender in these relationships. Furthermore, the role of smoking in relation to alcohol use and drunkenness was monitored.

Methods:

The study has been designed as a cluster randomized controlled trial with data collection before the program implementation and immediately after the implementation. In total, 486 schoolchildren participated in the trial ($M = 13.05$; 49.6% boys) and were randomly assigned to either an experimental ($N = 277$) or control group ($N = 209$). Binary logistic regression was applied and adjusted for gender and baseline risk behaviour.

Results:

There was no significant effect of Unplugged and no moderation effect of gender with regard to lifetime prevalence of drunkenness. However, smoking was also reported by those schoolchildren who reported drunkenness (OR 6.735; 95%CI 3.210-14.132). A significant program effect was found regarding the prevalence of alcohol use during the last 30 days. The schoolchildren in the experimental group had lower alcohol use in comparison to the control group (OR 0.501; 95%CI 0.253-0.993). The moderation effect of gender showed that the program had an effect on alcohol consumption in boys. After completing Unplugged, alcohol consumption in boys decreased significantly (OR 3.222; 95%CI 1.158-8.962). The results also confirmed that smoking is related to the prevalence of alcohol use during the last 30 days (OR 3.109; 95% CI 1.226-7.885).

Conclusions:

The findings confirmed that Unplugged reduced alcohol use among boys. It has been also shown that smoking is a significant predictor of alcohol use and drunkenness.

Key messages:

- The findings point to the role of gender differences in the effectiveness of a prevention program.
- The effectiveness of the preventive program is more pronounced for those schoolchildren who are more likely to use alcohol before the program, especially boys.

Adopting healthy habits through the collaboration of health, education and culture systems

Ana Puljak

A Puljak[1], M Maric Bajs[1], Z Sostar[1]
[1]Department of Health Promotion, Andrija Stampar Teaching Institute of Public Health, Zagreb, Croatia
Contact: ana.puljak@stampar.hr

Background:

The 'Adopt healthy habits' program is a health promotion program that links the health system, education system and the City of Zagreb library. It is based on the association of mental, physical and emotional health factors. It is done through work in smaller groups, using educational interactive materials and methods with selected books in accordance with the topic of the workshop and with the practice of applying the adopted knowledge.

Methods of work:

The methodological basis of the programs are health workshops conducted in the libraries of the City of Zagreb in cooperation with the primary schools. They imply working with students by acting on risk factors: obesity, physical inactivity, smoking and low self-esteem. The skills used are promoting health, cognitive-behavioral methods, health education, kinesiology, nutrition and bibliotherapy.

Objectives:

Educating students about the importance and ways of adopting healthy habits and gaining self-esteem and reducing the occurrence of risky behaviors. Long-term objectives are improvement of the psychophysical development of students, increase of the population of the City of Zagreb with balanced dietary habits and regular physical activity and normal body mass index and reduction of the occurrence of chronic non-communicable diseases in adulthood.

Results:

In the period from 2015 to 2018, a total of 141 workshops were conducted through which 3,106 pupils were educated. The workshops were conducted in 12 primary schools of the City of Zagreb and 5 of the related city libraries.

Conclusions:

Interactive approaches in the creative environment proved to be the most appropriate in educative work with children. It is necessary to continue to implement this form of primary prevention on a wider population.

Key messages:

- Adopting healthy habits in childhood is the basis for primary prevention of chronic non-communicable diseases.
- Multidisciplinary approach to health education in youth assures a more permanent adoption of positive health behavior.

School ethos and recurring sickness absence: a multilevel study of ninth grade students in Stockholm

Sara Brolin Låftman

S Brolin Låftman[1], *J Ramberg*[2], *B Modin*[1]
[1]Department of Public Health Sciences, Stockholm University, Stockholm, Sweden
[2]Department of Special Education, Stockholm University, Stockholm, Sweden
Contact: sara.brolin.laftman@su.se

Background:

A non-negligible proportion of Swedish students is recurrently absent from school due to various health problems. Recurring absence from school has potentially severe consequences for future prospects. Thus, identifying factors that may contribute to counteracting recurring sickness absence among students is important. The aim of this study was to investigate whether higher levels of teacher-reported school ethos were associated with lower levels of recurring sickness absence among their students, when adjusting for relevant confounders at the student- and the school-level.

Methods:

Data from four cross-sectional surveys performed in 2014 and 2016 were combined. The Stockholm School Survey was carried out among 9,298 ninth grade students (ages 15-16 years) in 147 school units, and the Stockholm Teacher Survey was performed among 2,024 teachers in the same units. School ethos was captured by an index of 12 teacher-reported items that was aggregated to the school-level. Recurring student sickness absence was based on self-reports and defined as absence on >10 occasions during the current school year. Student-level control variables were gender, family structure, parental education, parental unemployment and migration background. School-level control variables were sociodemographic composition and student-teacher ratio. Two-level logistic regressions were performed.

Results:

About 9.5% of the students reported recurrent sickness absence. Students attending schools with higher levels of teacher-rated school ethos had a lower likelihood of reporting recurring sickness absence compared with those attending schools with lower levels of ethos, even when adjusting for potential confounders at the student- and the school-level (OR 0.78, p = 0.015).

Conclusions:

Recurring sickness absence was less common among students attending schools with higher levels of teacher-rated ethos. The findings suggest that schools have the capacity to promote student health.

Key messages:

- A strong school ethos was linked with lower levels of recurring sickness absence among the students, even when adjusting for potential confounders at the student- and the school-level.
- A strong school ethos may contribute to counteracting recurring sickness absence among students.

Effects of educational policy on unhappiness of middle and high school students in Korea, 2006-2016

Sang Jun Eun

SJ Eun[1], *H-S Kim*[2]
[1]Department of Preventive Medicine, Chungnam National University College of Medicine, Daejeon, South Korea
[2]Korea Centers for Disease Control and Prevention, Cheongju, South Korea
Contact: zepplin7@cnu.ac.kr

Background:

Educational policies may have a substantial impact on health and well-being of students, who spend most of their daily lives at school. Policies on secondary education in Korea has changed in the late 2000s, which diversified college entrance exams (CEEs) and made the National Curriculum (NC) more autonomous to mitigate students' burden of preparing for CEEs. This study aimed to estimate effects of educational policy changes on unhappiness, which is known to be associated with health status such as mortality, morbidity, and prognosis, of students in secondary education.

Methods:

Using repeated cross-sectional self-reported data of 773,362 students in the Korea Youth Risk Behavior Web-based Survey during 2006-2016, cross-classified random effects models were fitted to estimate the fixed cohort effects of educational policy changes on unhappiness while considering individual factors and random effects of periods and grade cohorts.

Results:

Students' unhappiness increased when the NC began to become autonomous (odds ratio [OR] 1.21, 95% confidence interval [CI] 1.03-1.42), but it increased less after the autonomous NC was fully applied (OR 1.14, 95% CI 0.92-1.42). Two times of diversification of CEEs increased unhappiness (OR 1.21, 95% CI 1.06-1.38 for the first diversification and OR 1.33, 95% CI 1.07-1.67 for the second diversification). Unhappiness was high in students with high stress level (OR 7.59, 95% CI 7.43-7.75), low academic performance (OR 1.48, 95% CI 1.44-1.52), and low household economic status (OR 2.32, 95% CI 2.26-2.39).

Conclusions:

Enhancement of autonomy of the NC and diversification of CEEs increased students' unhappiness. Educational policy changes that diversified competencies required for college admission might result in an increase in academic burden in the context of Korea, where entrance into prestigious universities is crucial for success in life. Improvement of educational policy is needed to increase students' happiness.

Key messages:

- Educational policies may have a substantial impact on health and well-being of students, who spend most of their daily lives at school.

- Education policy changes in Korea increased students' unhappiness, which might be due to an increase in academic burden resulted from diversification of competencies required for college admission.

Satisfaction with health and oneself and the Unplugged program among Slovak Schoolchildren

Olga Orosova

O Orosova[1], B Gajdosova[1], J Benka[1]
[1]PJ Safarik University, Kosice, Slovakia
Contact: olga.orosova@upjs.sk

Background:

The investigation of protective factors and intervention effects on health are important issues of prospective studies. The aims of this study were to explore the changes in schoolchildren's satisfaction with their health and themselves (SH) following their participation in the Unplugged program (PU).

Methods:

This study was carried out as a cluster randomized controlled trial (1195 participating schoolchildren, Mean age = 11.52; 47.4% boys) with data collection conducted immediately before PU implementationT1, immediately after the implementationT2 then 3 monthsT3, 12 monthsT4, and 18 months after the implementationT5. The schools were randomly assigned to either an experimental (EG, n = 540) or control group (CG, n = 655). EG was exposed to PU consisting of 12 lessons (http://www.eudap.net/). The effect of participating in PU, gender, and self-efficacy (SET1) were explored in relation to changes in SH in both EG and CG. GLM Repeated Measures were used for the data analyses.

Results:

There was a significant main effect of time on SH, $F(4, 1096) = 6.685$, $p < 0.001$. The contrast analysis revealed that SH was significantly lower at every follow-up when compared to SH at T1. There was a significant interaction effect SHxSE, $F(4, 1096) = 2.868$, $p < 0.05$. The contrast analysis revealed that SH was significantly lower at T2 than at T1 among the schoolchildren with a lower level of SE. Finally, the SHxSExPU interaction was significant $F(4, 1096) = 2.779$, $p < 0.05$ and the contrast analysis revealed that SH was significantly higher at T5 than at T1 among those participants of PU with a higher level of SE.

Conclusions:

The findings generally suggest that while there was a decrease of SH among schoolchildren between T1 and T5 a long-term effectT5 of PU was found among the program participants with higher levels of SE who were able to maintain higher level of SH.

Key messages:

- Schoolchildren's satisfaction with their health and themselves was found to generally decrease in time during the 22 months when Unplugged was implemented and evaluated.
- A long-term effect of Unplugged was detected among program participants with higher levels of self-efficacy who were able to maintain higher level of satisfaction with their health and themselves.

Risks and success conditions for the French sanitary service of health students

Laurent Gerbaud

L Gerbaud[1], F Pizon[1], J Odoul[1], P Clavelou[2]
[1]Service de Santé Publique, Université Clermont Auvergne, CHU Clermont-Ferrand, CNRS, SIGMA Clermont, Institut Pascal, Clermont-Ferrand, France
[2]Service de Neurologie, Faculté de Médecine, Université Clermont Auvergne, CHU Clermont-Ferrand, Clermont-Ferrand, France
Contact: lgerbaud@chu-clermontferrand.fr

Background:

French sanitary service of health students was a pledge of the French Presidency. It is mainly presented as a massive information campaign on good practices in health made by "thousands of health students going into the enterprises and schools". We tried to skip this orientation and to go to actions in favor of people's empowerment and ability in health choices.

Objectives:

Our program was designed to change students' ideas on prevention, by focusing on reflexivity, motivational approaches, education and ethic in health promotion, of peer-to-peer effects and concrete use of educational tools for teen-agers groups. We developed students' autonomy and ability to negotiate their project with the prevention structures. Training was 11 workshops (2 hours each), of 15 to 20 students (mixing medical, pharmaceutical, dental and midwives), and e-learning. Then they had 5 months to negotiate with their place of intervention (secondary schools and apprenticeship centers) and create their own new project. Intervention lasted for one week, full time, in various teen-agers settings, so that to reduce social and territorial inequities in health.

Results:

After a first test (28 students in 6 settings), 250 students acted in 72 teen-agers' facilities. Problem occurs in 1 case (lack of negotiation and preparation before the intervention) and satisfaction of both students and facilities are high. At the same times, we had to face constraints due to double bind policies of the state authorities (i.e. as asking for more training time and reducing training financing, asking to send students in deprived or isolated areas and reimbursing scarcely the costs).

Conclusions:

An educational program on training and students' autonomy works if we take care on five points: learning of educational process in health, control of peer-to-peer effects, reduction of health inequities, and reinforcement of local health promotion policies. This also needs state policies that are ready to play the game.

Key messages:

- Training of health students to develop their autonomy and ability in health education works.
- Inconsistency in State policies is the major problem.

The trends in health behaviour of the first-year students from Kaunas universities, 2000 - 2017

Janina Petkeviciene

J Petkeviciene[1], V Kriaucioniene[1]
[1]Faculty of Public Health, Lithuanian University of Health Sciences, Medical Academy, Public Health Faculty, Kaunas, Lithuania
Contact: janinapet@gmail.com

Background:

First-year university students are exposed to different factors affecting their lifestyle. The aim of the study was to evaluate the trends in health behaviour of first-year students from four Kaunas universities over 17 years.

Methods:

The study was carried out in 2000, 2010 and 2017. In total, 689, 739 and 1062 randomly selected first-year students participated (response rates >90%). During the lectures, participants filled in the anonymous questionnaire that included information on nutrition, physical activity, harmful habits, height, and weight.

Results:

The reduction in daily smoking was observed: from 30.2% in 2000 to 18.4% in 2017 among males and from 21.1% to 15.9% among females, respectively. The proportion of male students drinking alcohol at least once a week declined from 62.7% in 2000 to 31.6% in 2017 and the proportion of females - from 41.5% to 27.3%, respectively. There was an increase in the proportion of students who have tried or are taking drugs: from 15.9% in 2000 to 27.8% in 2017 among males and from 4.8% to 18.8% among females, respectively. The changes in the nutrition habits of the students were observed: the proportion of students who consumed red meat every day decreased (up to 35.6% in 2017). In 2017, more students consumed cereals, fresh fruits and vegetables every day and fewer sweets, confectionery and soft drinks at least once a week than in 2000. There was a decline in meantime students spent sitting as well as in the average duration of the sleep. The proportion of students who take part in sports activities has increased by 17.1%. However, the prevalence of overweight and obesity increased from 11.7% in 2000 to 23.7% in 2017 among males, and from 4.2% to 9.0% among females, respectively.

Conclusions:

Over 17 years, most health behaviours of the first-year students have changed in a positive direction; however, some unhealthy habits are still common and the prevalence of overweight has increased.

Key messages:

- This study highlights the importance of implementing preventive programmes among students after starting university.
- Monitoring of changes in health behaviour of students helps timely respond to the challenges.

Perception of Social Gender Roles in Medical Faculty Students

Hatice Aygar

H Aygar[1]*, B Isıktekin Atalay*[1]*, S Akbulut Zencirci*[1]*, A Unsal*[1]*, D Arslantas*[1]

[1] Department of Public Health, Eskisehir Osmangazi University Medicine Faculty, Eskisehir, Turkey

Contact: haticeaygar1990@gmail.com

Background:

‘‘Gender equality’’ is the fifth of the Sustainable Development Goals put forward in order to ensure the development in all areas. Medical faculty students, who will be a doctor, should practice with a gender equality perspective and shape their views and attitudes with equality in mind which will have an important part in the adoption of equality by society. The aim of the study was to evaluate the perception of social gender roles in medical students.

Methods:

This cross - sectional study was performed with all students in Eskisehir Osmangazi University Faculty of Medicine. The questionnaire includes sociodemographic characteristics and Gender of Perception Scale(PCS) to measure perception of social gender roles. The scores that can be taken from the scale are ranged from 25 to 125, and high scores indicate that perception of gender is positive and equality. Mann Whitney U, Kruskal Wallis were used in univariate analysis; multivariate linear regression was used in multivariate analysis.

Results:

The study group consisted of 1023 (84.3%) students in the study group, 52.8% were females and their ages ranged from 17 to 30 and the mean was 21.36 ± 2.06. The PCS scores ranged from 32 to 125 and the mean was 108.07±16.58. Multivariate linear regression analyzes were performed to determine the factors associated with the PCS. According to the results of last model sex, living with grandparents until the age of 18, region of the majority of life and parental attitudes were found to be related to perception of social gender roles ($F = 29.602$, $R2 = 0.170$, $p < 0.001$).

Conclusions:

The perception of gender of medical students was found to be positive. Sex and the characteristics of the social environment were related to perception of gender. In order to raise awareness on gender equality, it might be useful to ensure integration in the medical education curriculum.

Key messages:

- Factors that can be changed, such as the social characteristics of the living environment, were found to be related to perception of social gender roles.
- Ensuring gender equality, one of the Sustainable Development Goals, is important for medical students who will be a role model for society.

School connectedness and adult depressiveness, longitudinal study of the Northern Swedish Cohort

Hrafnhildur Gunnarsdottir

H Gunnarsdottir[1,2]*, G Hensing*[1]*, A Hammarström*[3,4]

[1] Department of Public Health and Community Medicine, University of Gothenburg, Gothenburg, Sweden

[2] Department of Health Sciences, University West, Trollhättan, Sweden

[3] Department of Public Health and Caring Sciences, Uppsala University, Uppsala, Sweden

[4] Stress Institute, Stockholm University, Stockholm, Sweden

Contact: hildur.gunnarsdottir@gu.se

Background:

The aim of this study was to use Bronfenbrenner’s ecological theory to investigate adolescents’ school connectedness and family climate as potential predictors of depressiveness in adulthood. **Methods:** The data are from the Northern Swedish Cohort and the sample consists of 481 women and 526 men born 1965 that participated in data collection at four time points, at age 16, 21, 30 and 43. Multivariate linear regression was used to examine the associations between school connectedness and family climate and depressiveness, respectively.

Results:

Poor school connectedness was found to be associated with depressiveness up to mid adulthood and social/material adversities in adolescence were found to expand this association in young adulthood. **Conclusions:** This study show that poor school connectedness can have long lasting effects on mental health. Thus, mental health promoting initiatives with holistic approach aiming at enhancing both sense of belonging in school, peer relations and academic achievements are needed. The study accentuates the complex processes determining mental health and propose a theoretical approach appealing for public mental health research. To advance the knowledge of the mechanisms behind the associations between proximal processes and depressiveness in adulthood, additional life-course studies are called for.

Key messages:

- Poor school connectedness can have long lasting effects on mental health.
- Initiatives aiming at enhancing both sense of belonging in school, peer relations and academic achievements are needed.

3.S. Chronic disease and burden

An ordinary life with chronic condition as a goal for medicine

Marie Gaille

Ms Gaille[1]*, Ms Camus*[1]

[1] SPHERE, CNRS, Paris, France

Contact: mariegaille@yahoo.fr

Background:

Social sciences and humanities have developed a significant interest about chronic condition since the 1960, examining the ‘‘biographical disruptions’’ it seems to entail and the coping capacities of individuals. The present study, funded by IreSP, aims at developing a new conceptual and normative perspective: to explore the idea of ‘‘normal’’ life with chronic condition. This perspective allows for taking into account the expression of the wish for a ‘‘normal life’’ actually expressed by persons with chronic condition. On the basis of this research perspective, the present study aims at assessing the possibility to live such a life with chronic condition as a goal for the health care systems. As it may have substantial implications in terms of health care organisation and orientation, this research is important to ground public health policies.

Methods:

1.Review of literature (philosophy of the forms of life and of ordinary life, social sciences' critical assessment of the ''injunction to normality'', ethnographic works on the expression of the whish for a normal life)

2.Analysis of the theoretical and ethical resources of the philosophical works by G. Canguilhem and K. Goldstein

Results:

-Elaboration of a philosophical conceptual and normative frame based on the notion of ''ordinary life'' and of a ''reinvented normality''

-Attention paid to the ''milieu'' of life of the person and its adjustment to her capacities.

-Identification of the technological tools and care practices contributing to such a reinvention.

Conclusions:

The study presents the conceptual and normative results of a philosophical analysis careful of the challenge raised by the wish for a ''normal life'' expressed by people with chronic condition. It proposes some conceptual and normative tools to answer this challenge. It formulates this challenge as an issue for the health care systems and the organisation of medical care, its places (institutions of various types and/or home) and its goals.

Key messages:

- The wish for a ''normal life'', ''a life like everyone's life expressed by persons with chronic condition should by taken into account by the health care system.
- Philosophy offers some conceptual and normative tools to medical care to answer this wish.

Education and T2DM: the role of differential exposure and susceptibility to overweight and obesity

Jimmi Mathisen

J Mathisen[1], AKG Jensen[2,6], I Andersen[1], GS Andersen[3], UA Hvidtfeldt[4], NH Rod[5]

[1]Section of Social Medicine, University of Copenhagen, Copenhagen, Denmark
[2]Section of Biostatistics, University of Copenhagen, Copenhagen, Denmark
[3]Steno Diabetes Center, Capital Region, Copenhagen, Denmark
[4]Danish Cancer Society Research Center, Danish Cancer Society, Copenhagen, Denmark
[5]Section of Epidemiology, University of Copenhagen, Copenhagen, Denmark
[6]Division of Epidemiology and Biostatistics, School of Public Health, University of California, Berkeley, USA
Contact: jima@sund.ku.dk

Background:

There is a clear educational gradient in type 2 diabetes and differential exposure and susceptibility to overweight and obesity across educational groups may explain part of this gradient. Previous studies have mainly addressed differential exposure to overweight/obesity, even though the pathways are highly intertwined. We take advantage of novel methodological developments to assess the simultaneous contribution of both pathways. We further compare these analyses to more traditional approaches.

Methods:

A prospective cohort of 53,159 Danish men and women, aged 50-64 years at enrollment in 1993-1997, were followed for a mean of 14.7 years. We used national register data to ascertain education and incident type 2 diabetes. Overweight/obesity was determined by BMI. Using a marginal structural approach and a three-way effect decomposition, we estimated rate differences of type 2 diabetes by education and decomposed these into direct, indirect and mediated interactive proportions. We compared this approach to traditional and separate approaches to mediation and interaction analysis.

Results:

Compared with high education, medium education was associated with 316 (95% CI: 268-363) extra cases of type 2 diabetes per 100,000 person-years, and low education with 454 (95% CI: 398-510) extra cases. Differential exposure to overweight/obesity accounted for 29% (95% CI: 24-36) and 37% (95% CI: 31-45) of the cases in the medium and low educational levels, respectively, while differential susceptibility accounted for 6% (95% CI: 3-10) and 9% (95%CI 4-14). Traditional approaches suggested stronger effects of both pathways.

Conclusions:

Differential exposure and susceptibility to overweight/obesity are both important pathways in the education-type 2 diabetes association, and the results emphasize the importance of addressing them simultaneously.

Key messages:

- Lower educated groups are more exposed and susceptible to the adverse effects of overweight/obesity with regard to type 2 diabetes, suggesting a large preventive potential.
- Future studies could benefit from estimating both differential exposure and differential susceptibility to better understand social inequality in type 2 diabetes and other health outcomes.

Machine learning application to the reduction of ambulatory care sensitive admissions (ACSA)

Gregoire Mercier

T Ngo[1,2], V Georgescu[1], C Gervet[3], A Laurent[2], T Libourel[3], G Mercier[1]

[1]Economic Evaluation Unit, University Hospital of Montpellier, Montpellier, France
[2]LIRMM, University of Montpellier, Montpellier, France
[3]Espace-Dev, University of Montpellier, Montpellier, France
Contact: gregoire_mercier@hotmail.com

Background:

Reducing Ambulatory Care Sensitive Admissions (ACSA) not only enhances patients' quality of life but could also save substantial costs. ACSA are avoidable admissions for chronic conditions that are associated with socio-economic status, health status, utilization and readiness of primary care service as well as environmental factors. Undoubtedly, health authorities are highly interested in enhancing the health care services in order to reduce the number of ACSA. The objective is to identify the geographic areas where the primary care workforce should be increased in order to maximize the decrease in ACSA.

Methods:

Using ambulatory care and inpatient claims data as well as contextual variables, we apply support vector machine regression (SVR) to select the geographic areas (fr. Bassins de vie - BVs) and the number of to-be-added primary care nurses that maximize the ACSA reduction. We also take into account the constraints related to budget and the equality of health care access. Particularly, there are three possible constraints: (1) the total number of nurses can be added in the whole region; (2) the maximum number of the nurses can be added at each area; (3) the maximum density of nurses (numbers of the nurses per 10,000 habitants) can be reached at each area. The results are visualized using spatial maps.

Preliminary results:

In 2014, 27,000 ACSA occurred in the Occitanie, France region. For a specific set of constraints values, the model identified 16 BVs (out of 201) where the addition of 30 nurses could lead to the maximum ACSA reduction in number which is 17.

Conclusions:

In the French Occitanie region, our SVR model was able to target a small number of geographic areas to maximize the impact of increased primary care workforce on ACSA. Our approach is applied to a single region, and it can be applied to other regions or extended at the national level as well as to other countries.

Key messages:

- A decision support tool to help health authorities in locating primary health care resources for the maximum reduction of ambulatory care sensitive admissions.
- An application of machine learning in primary care services.

Presence of intimate family and cancer screening behavior: a cross-sectional study of 4237 workers

Naomi Miyamatsu

N Miyamatsu[1], *A Shima*[1,2], *A Morino*[1,2], *S Azuma*[1], *M Ichikawa*[1], *K Godai*[3], *Y Kawatsu*[2], *T Nishikawa*[4], *H Tanaka*[5], *T Okamura*[6]
[1]Shiga University of Medical Science, Otsu, Japan
[2]Heiwado Co., Ltd., Hikone, Japan
[3]Osaka University, Suita, Japan
[4]Kyoto Koka Women's University, Kyoto, Japan
[5]Fujiidera Public Health Center, Osaka, Japan
[6]Keio University, Tokyo, Japan
Contact: miyan@belle.shiga-med.ac.jp

Background:

Presence of intimate family is considered as one of the related factors of health behaviors. The study aim was to clarify the relationship between the presence of significant others and having a colorectal cancer screening.

Methods:

This study used data of baseline survey of intervention study regarding breast cancer screening at worksites. A total of 6827 workers, aged 40 and over of the retail company, were required to fill out a self-administrated questionnaire related to cancer screening. the intimate family was defined as a person's spouse or partner and children. Logistic regression analyses were performed to estimate odds ratios [ORs] and 95% confidence intervals [CIs] of undergoing an annual screening for colorectal cancer by the presence of spouse or partner adjusting for age. The same analysis was performed regarding the presence of children.

Results:

Response rates were 70% in men and 71% in women. After excluding participants with a past history of cancer and lack of information about colorectal cancer screening or the presence of significant others, 4203 remained for the analyses. A total of 1777 participants reported that they had undergone screening for colorectal cancer within a year (42% in men and 42% in women). Screening rates of participants with/without a spouse were 45% and 30% in men, 44% and 38% in women. Screening rates of participants with/without children were 45% and 33% in men, 43% and 38% in women. ORs of undergoing annual colorectal cancer screening by the presence of spouse were 1.8 (1.3-2.5) in men and 1.3 (1.1-1.5) in women. ORs by the presence of children were 1.6 (1.2-2.1) in men and 1.1 (0.9-1.3) in women.

Conclusions:

This study indicated that health behavior in cancer screening could be affected by having a spouse in both men and women. The presence of children positively related in men. Male workers with children might be under some pressure to keep their health, from a sense of responsibility of main income earner.

Key messages:

- Health behavior in cancer screening could be affected by having a spouse.
- Health behavior in cancer screening could be affected by having a child only in men.

The status of compliance with guidelines of cancer screening in Japan

Kanako Kono

K Kono[1,2], *K Matsuda*[3], *R Machii*[3], *K Saika*[3], *H Takahashi*[1,3], *T Nakayama*[1]
[1]Screening Assessment and Management, National Cancer Center, Tokyo, Japan
[2]Medical Science Specialty, Keio University Graduate School of Medicine, Tokyo, Japan
[3]Medical Support and Partnership, National Cancer Center, Tokyo, Japan
Contact: kkono@ncc.go.jp

Background:

The Ministry of Health, Labour and Welfare (MHLW) establishes screening recommendations specifying screening methods, age, and interval for gastric, colon, lung, breast, and cervical cancers. Screening programs are provided via local healthcare departments (LHD), who are responsible for managing programs and reporting the screening status through a survey annually.

Methods:

We analyzed screening status provided by LHDs in fiscal 2017 in regards to appropriate screening age and interval. Briefly, current recommended screening age by MHLW is followed: colon, lung, breast cancer screening are age 40 years and older, and cervical cancer for aged 20 and older, and gastric cancer for aged 50 and older. Screening intervals are gastric, breast, and cervical cancer screening are two years, and colon and lung cancer screening are one year.

Results:

The survey was completed by 1736 LHD (response rate: 99.9%). Regarding age-appropriate compliance, in cervical cancer, 96.4% of LHDs reported following recommended target age, while compliance was lower for lung, colon, breast, and gastric cancers at 79.4%, 75.7%, 60.2% and 4.2%, respectively. High compliance with recommendations for screening interval was identified for colon (99.7%) and lung (98.7%) cancers; this was substantially less for breast, cervical, and gastric cancer screening at 39.8%, 34.1%, and 4.6%, respectively.

Conclusions:

In 2016, MLHW changed the starting screening age for gastric cancer from 40 to 50 years old, likely resulting in the lowest compliance in our analysis. Though it may take time for screening facilities to come into compliance with newer recommendations. Many LHDs provide screening without adhering to recommended starting ages, with a general tendency to provide screening at younger than recommended ages. This is a barrier to maximizing effectiveness and minimize harms of screening and warrants closer monitoring to promote efficiency in cancer screening programs.

Key messages:

- There is relatively low compliance with cancer screening guidelines in Japan.
- Establishing an environment of appropriate monitoring and support to achieve the goal of cancer screening is warranted.

Patients' participation in the colorectal cancer screening program and their health beliefs

Snieguole Kaseliene

S Kaseliene[1], *O Mesceriakova-Veliuliene*[1]
[1]Department of Health Management, Lithuanian University of Health Sciences, Kaunas, Lithuania
Contact: skaseliene@gmail.com

Background:

Both morbidity and mortality rates from colorectal cancer (CRC) have been increasing in Lithuania. However, only about 50% of the target Lithuanian population was involved in CRC screening in 2018. The aim of this study was to evaluate associations between the involvement of 50- to 74-year-old primary care patients in CRC screening and their health beliefs as well as awareness about this screening.

Methods:

A cross-sectional study was conducted in September-November 2016. A total of 390 patients aged 50-74 years were anonymously surveyed at 10 primary health care institutions of Šakiai region, Lithuania. The response rate was 86.7%. Chi-square and z tests were used to determine a relationship between two nominal (categorical) variables ($\alpha = 0.05$).

Results:

43.1% of the respondents noted about their participation in the CRC screening program. Those who had participated in the program more often ($p < 0.05$) than nonparticipants reported to be worried about getting CRC (60.6% vs 43%) and thought that this could happen already in the next year (16.8% vs 6.5%), more frequently believed that the possibility of getting CRC for them was very high (74.8% vs 60.9%), that they had predisposition to CRC (44.9% vs 27.6%) and that CRC screening will prevent them from problems in the future (97.4% vs 90.9%). The participants of the CRC screening program also more frequently ($p < 0.05$) than nonparticipants noted that they had heard about this program before their involvement in it (98.8% vs 70.9%) and got this information from their family doctor 2.1 times more frequently (88.1% vs 41.4%). Nearly half (47.3%) of the program participants and 30.6% of the nonparticipants mentioned that the responsibility for participation in the CRC screening program should be taken by patients themselves ($p < 0.05$).

Conclusions:

Participation of patients in the CRC screening program is related to their health beliefs, awareness and active engagement of family doctors in CRC screening programs.

Key messages:

- The patients who had participated in the CRC screening program had more negative health beliefs regarding CRC and were better informed on the program by their family doctor than nonparticipants.
- Family doctors should pay more attention to informing patients about CRC and its prevention.

Standardization of the Cancer Health Literacy Test – 6 in a non-cancer populations

Levent Dumenci

L Dumenci[1], *LA Siminoff*[2]
[1]Epidemiology & Biostatistics, Temple University, Philadelphia, USA
[2]College of Public Health, Temple University, Philadelphia, USA
Contact: ldumenci@temple.edu

Background:

The Cancer Health Literacy Test-6 (CHLT-6) was originally developed in a cancer population to identify persons with limited cancer health literacy (LCHL). There is no instrument to identify individuals with LCHL in non-cancer populations such as caregivers and epidemiologic samples. This study aims to test if the CHLT-6 can be used to identify persons with LCHL in non-cancer patient populations. The CHLT-6 was administered using a hand-held touch-screen computer.

Methods:

A patient sample of 512 persons was used to test the CHLT-6 measurement structure and externally validate the test. English speaking, aged 18 or higher, and no history of cancer diagnosis were used as eligibility criteria. Participants were recruited from health fair grounds, primary care clinics, and community centers in the Mid-Atlantic region of the U.S.A. Consistent with the analysis of the developmental sample, discrete latent variable modeling was used as the underlying measurement structure of the instrument.

Results:

Two classes were clearly separated by the CHLT-6 items. Measurement invariance tests showed equivalence of conditional probabilities between gender, race/ethnicity, and educational groups. There were significant group differences in prevalence of LCHL. The CHLT-6 was externally validated using race/ethnicity, education, and income. Overall results were very similar to those reported in the cancer population.

Conclusions:

The CHLT-6 is the first and only instrument to identify individuals with LCHL using a discrete latent variable framework. Measurement invariance tests provided empirical evidence that labels used to describe latent classes (i.e., limited and adequate cancer health literacy) have the same meaning between gender, race/ethnicity, and educational groups. Persons self-described as African Americans and low educational attainments have a high probability of belonging to the LCHL class.

Key messages:

- There is a strong support for psychometric properties of the CHLT-6 in a cross-validation sample.
- This study provides empirical basis for using the CHLT-6 in non-cancer populations.

Comparison of Cardiovascular Disease Risks of Actual and Perceptions of Men's that 40-65 Years Old

Sebahat Gözüm

İbrahim Topuz[1], *Sebahat Gozum*[2]
[1]Faculty of Health Science, Nursing Department, Amasya University, Amasya, Turkey
[2]Public Health Nursing, Faculty of Nursing, Akdeniz University, Antalya, Turkey
Contact: sgozum@akdeniz.edu.tr

Background:

Turkey is among the top countries in Europe in coronary mortality in the 45-74 age range. The highest death due to disorders of the circulatory system (50.8%) that is Amasya province.

Objective:

Determine related factors and to compare with actual and perceived cardiovascular disease (CVD) risks of men aged 40-65 living in Amasya.

Methods:

The sample size of cross-sectional and analytical study consisted of 400 people who met the inclusion criteria. Actual CVD risks of men were calculated using HeartScore. Age, systolic blood pressure, total cholesterol measured by blood taken from the capillary and smoking status were used to calculate CVD risk. Actual CVD risk in next decade has been calculated as low, medium, high or very high. Perceived CVD risk in next decade were identified by participants as low, medium, high and very high responses. They also questioned why evaluation of perceived risk.

Results:

It was determined whereas 8.3% of the males had high, 52.5% had a very high level of CVD risk. The main variables affecting actual CVD risk; diastolic blood pressure, BMI and physical activity. 13.3% of males perceived CVD risks at high and 8% at very high. The main variables affecting perceived CVD risk; age and DM. It was found that 48% and 23.8% of males perceived CVD risks lower and higher than actual CVD risk while 28.2% were accurate. Those who perceived CVD risk at a moderate, high and very high think that this is caused by diseases that increase the risk of CVD and smoking.

Conclusions:

Approximately 1/2 men has very high risk of CVD. It was determined that 1/2 men perceived risks are lower with false optimism and couldn't accurately identify risks of people older and with diabetes.

Key messages:

- It can be ensured that develop risk reducing behaviors and individuals with high risk of CVD can raise their awareness.
- The risk perceptions of males in the very high-risk group from the past to the present are important because they affect their actual risks and risk-reducing behaviors.

Increased risk of Roma for 10-year development of CVDs based on Framingham Risk Score calculation

Peter Piko

P Piko[1,2], *S Fiatal*[2,3], *Z Kosa*[4], *J Sandor*[2, 3], *R Adany*[1,2,3]
[1]MTA-DE, Public Health Research Group of the Hungarian Academy of Sciences, Faculty of Public Health, University of Debrecen, Debrecen, Hungary
[2]Department of Preventive Medicine, Faculty of Public Health, University of Debrecen, Debrecen, Hungary
[3]WHO Collaborating Centre on Vulnerability and Health, Department of Preventive Medicine, Faculty of Public Health, University of Debrecen, Debrecen, Hungary
[4]Department of Health Visitor Methodology and Public Health, Faculty of Health, University of Debrecen, Nyíregyháza, Hungary
Contact: pikopeter@gmail.com

Background:
Increased mortality and short life expectancy of Roma are well known epidemiological findings which can be partially explained by the high prevalence of cardiovascular risk factors among them. This study assesses the prevalence of the cardiovascular disease (CVD) risk factors (age, sex, systolic blood pressure, smoking and diabetes status, elevated total and reduced high density lipoprotein cholesterol level (HDL-C)) and the estimation of 10-year risk of development of CVD (CVD in general, coronary heart disease (CHD), myocardial infarction (MI) and stroke) and that of death from CHD and CVD based on the Framingham Risk Score (FRS) in case of the Hungarian general (HG) and Roma (HR) populations.

Methods:
A complex health survey incl. questionnaire based interview, physical examination and laboratory test was carried out in 2018 on the HG and HR populations. The prevalence of different cardiovascular risk factors was defined and FRS was computed and compared between the HG (n = 378) and HR (n = 386) populations.

Results:
The prevalence of diabetes was significantly higher among Roma females compared to females of general population (17.8% vs. 7.7%; p = 0.001) while the average systolic blood pressure level was less elevated among Roma males (127.9 mmHg vs. 129.4 mmHg; p = 0.020). The prevalence of smoking (males: 63.1% vs. 33.7%; females: 67.6% vs. 31%; $p < 0.001$) and reduced HDL-C level (males: 40% vs. 25.9%, p = 0.014; females: 55.5% vs. 35.1%, $p < 0.001$) were significantly higher in both sexes among Roma. The 10-year estimated risk for development of CHD, MI and CVD and the death from CHD was significantly ($P < 0.05$) higher in both sexes among Roma compared to the general population while the average risk scores for stroke and death from CVD were significantly higher only among Roma men.

Conclusions:
Our results show that both sexes in the Roma population have a significantly higher risk for 10-year development of CVD compared to the Hungarian general population.

Key messages:
- The Roma population have a significantly higher risk for 10-year development of cardiovascular diseases and death from them based on the Framingham Risk Score.
- The targeted cardiovascular interventions should be focus on reduce smoking and provide information on the recognition and treatment of diabetes and lipid disorders among Roma.

Economic burden of diabetes in France between 2012 and 2017 based on French national claim database

Pierre Denis

P Denis[1], *A Aguadé*[1], *T Lesuffleur*[1], *L Pestel*[1], *M Nicolas*[1], *A Rachas*[1], *C Gastaldi-Menager*[1]
[1]CNAM, Paris, France
Contact: pierre.denis@assurance-maladie.fr

Background:
The aim of this study is to assess the economic burden of diabetes in France based on a top-down allocation of health care expenditure, and to analyze structure and trends of expenditure between 2012 and 2017.

Methods:
Using information about 57 millions of individuals from the general scheme insurance database (87% of the French population), we applied algorithms based on ICD-10 diagnoses, long-term diseases, and specific treatments. All reimbursed expenditure (drugs, medical visit and other ambulatory care, hospitalization, disability/sickness benefits) were extracted for each individual. A top-down method was used to allocate expenditure to diabetes. To analyze trends, we applied the same methodology from 2012 through 2017.

Results:
In 2016 (results for 2017 will be available for the conference), among the 137 billion euros reimbursed, 6.8 billion (5%) were attributed to diabetes and 3.2 million people were concerned (5.5% of the population). Drugs represented the main expenditure item (31% of the average annual expenditure per patient related to diabetes), followed by nursing (18%) and medical devices (17.5%). From 2012 to 2016, the number of people with diabetes increased by 11.4% (+322 700) with an increase by 2.7%/year, the expenditure attributed to diabetes increased by 2.3%/year. The average expenditure per patient in 2016 was about €2150, slightly decreasing from 2012, mainly due to price controls on antidiabetics drugs which permits to limit expenditure growth.

Conclusions:
Our study shows the high economic burden of diabetes in France with a detailed analysis of expenditures and their main drivers. With the arrival of innovation and predicted increase of the number of patients partly related to ageing process, control of expenditure must be a priority. The developed tool will help decision makers to monitor the burden of diabetes but also to provide stakeholders with a better understanding of trends and regulating actions.

Key messages:
- Diabetes represents a high proportion of healthcare expenditure in France.
- With the arrival of innovation and predicted increase of the number of patients partly related to ageing process, control of expenditure must be a priority.

Economic burden of cardiovascular diseases from 2012 to 2017 based on French national claim database

Muriel Nicolas

M Nicolas[1], *L Pestel*[1], *S Rivière*[1], *A Rachas*[1], *C Gastaldi-Menager*[1]
[1]Department of Studies on Diseases and Patients, Caisse Nationale d'Assurance Maladie, Paris, France
Contact: muriel.nicolas@assurance-maladie.fr

Background:
The purpose of this study was to assess the economic burden of cardiovascular diseases (CVDs) in France by analysing the structure and the growth of expenditure attributed to these diseases between 2012 and 2017.

Methods:
For each year, 11 CVDs were identified from SNDS data using algorithms based on long-term disease registry and hospitalization diagnoses, applied to the population of national health insurance general scheme beneficiaries. The individuals' expenditure (26 different items) reimbursed for hospitalisations, ambulatory care and cash payments were included. A top-down method was used to attribute expenditure to each considered groups of diseases based on the average expenditure by disease calculated for individuals with only one disease. To analyse trends, we applied the same methodology from 2012 to 2017.

Results:
In 2017, of the €140.1 billion reimbursed, €14.0 billion (10.0%) were attributed to the care of 4.0 million people with a CVD (7.0% of the population). Short-stay hospitalisations accounted for 33% of this total expenditure. This proportion was higher for acute CVD (coronary syndrome: 64%, stroke: 56%, heart failure: 65%, pulmonary embolism: 69%) but also for valvular heart disease (50.0%). Medications represented almost 13% of the expenditure attributed to all CVDs, and up to 25% for chronic coronary heart disease. Disability pension essentially concerned sequelae of stroke (12% of the expenditure attributed to this disease). Between 2012 and 2017, the total expenditure attributed to CVDs increased by 3.3% per year, mainly due to the annual mean increase of the number of patients over the period (+3.1%).

Conclusions:
These results demonstrate the high economic burden of CVDs in France with a detailed analysis of expenditures and their main drivers. The developed tool will help decision makers to monitor the burden of these diseases but also to provide stake holders with a better understanding of trends and regulating actions.

Key messages:
- Economic burden of CVD in France is high: 10% of healthcare expenditure.
- Implementation of public health policy to prevent CVD and control risk factors must be a priority.

4.R. Infectious diseases control between policy and epidemiology

Tuberculosis screening for foreign students change: good saving and bad idea?

Laurent Gerbaud

L Gerbaud[1,2,3], B Chabanas[1], A Perrève[1], Bureau de l'ADSSU[3]
[1]Service de Santé Universitaire, Université Clermont Auvergne, Clermont-Ferrand, France
[2]Service de santé publique, Université Clermont Auvergne, CHU Clermont-Ferrand, CNRS, SIGMA Clermont, Institut Pascal, Clermont-Ferrand, France
[3]ADSSU, Maison des Universités, Paris, France
Contact: lgerbaud@chu-clermontferrand.fr

Issue:

There was a mandatory screening of tuberculosis (TB) for the 60.000 foreign students (out of European Union) annually newcomer in France. It was organized by screening centers of the Office of Immigration and Integration, a State agency. There was a link with university students' health services (USHS) by systematic exchange of data, and sometimes the USHS was in charge of this screening and financed for that. In March 2016, a law, applied since January 2017, stopped this obligation, and transferred the responsibility of a ''preventive survey'' to USHS, without any means and financing.

Problem:

As the decision was made without any data, thanks to the national network of UHSH, we made a brief national survey showing a 2,7 to 7,9/1.000 incidence, from year to year, 40% being active. About 50% of the cases came from North Africa and China. These data did not changed the decision, and we present its consequences in one French University, which was a previous TBI screening center. We computed all the cases of TB known in our USHS, since 2010, completed by the data form health authorities.

Results:

Since screening is not anymore mandatory we faced a global refusal from Chinese and Moroccan students arguing that there was no TB in their country. Number of foreign students and their origin were approximately stable from 2010 to 2016, and mean TB incidence was 1,97/1.000. Students from China and North Africa represented half of the cases and 40% were latent TB. Since January 2017, TB incidence lowers to 1,51/1.000. Latent TB represent less than ¼, and there was no more cases screened from North Africa and China, while there was no change in foreign students origins, showing a significant degradation of screening effectiveness.

Lessons:

The main reason for screening cessation was to save public money. Due to important lack of knowledge among French state authorities, we couldn't change a decision which threatens the TB epidemic control.

Key messages:
- Cost saving policy reduced the effectiveness of tuberculosis screening.
- Health policy decisions may not take into account epidemiologic objectives.

Healthcare workers and measles outbreaks in Italy: is it time to act? A systematic review

Corrado De Vito

V Baccolini[1], A Sindoni[1], G Adamo[1], A Rosso[1], A Massimi[1], E Pitini[1], C De Vito[1], C Marzuillo[1], P Villari[1]
[1]Department of Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy
Contact: corrado.devito@uniroma1.it

Background:

Despite healthcare workers (HCWs) vaccination against measles is strongly recommended in Europe, many studies showed their low vaccination coverage and a significant involvement in hospital and community outbreaks. The aim of this systematic review was to analyze the available evidence on HCW role in measles outbreaks and identify the epidemiological characteristics of the transmission patterns related to HCW infection.

Methods:

PubMed, Scopus and ISI Web of Science were searched to detect the measles outbreaks occurred in Italy and involving at least one HCW. English or Italian records were considered eligible. The quality assessment was performed using the ORION checklist. We also analyzed national or regional measles reports and the Measles outbreaks reporting forms that are annually submitted to the World Health Organization (WHO) of the period 2014-2018.

Results:

Twenty-one articles were identified in the literature search and were in general of good quality. Of these, six were regional or Italian reports, two referred to one city, 13 were single outbreak reports. The national data showed that the number of infected HCWs increases with the rise of the total number of cases. A total of 72 descriptions of measles outbreaks were retrieved from the WHO reports. The vast majority was confined to the hospital or started at the hospital and spread in the community. The index cases were mainly patients seeking care for measles-related symptoms but, in the last years, a growing number of infected HCWs was identified as infection source. Similarly, the number of outbreaks with more than one infected HCW recorded a small increase over time.

Conclusions:

HCWs play a critical role in measles transmission especially in hospital outbreaks, which are significantly costly and disruptive for the healthcare delivery quality and safety. Vaccination policy aiming at increasing their immunization rate is crucial to limit the virus spread and the economic impact on the institutions.

Key messages:
- In spite of the remarkable progress, measles elimination in Italy is far from being met and the virus transmission in healthcare settings is increasingly notified.
- Vaccination policies aiming at increasing HCW immunization coverages are essential.

Monitoring measles outbreaks using emergency department data in France

Guilhem Noel

G Noel[1,2], F Franke[3], C Forgeot[4], J Piarroux[1], G Viudes[5], C Caserio-Schönemann[4]
[1]Pediatric Emergency Department, APHM, Marseille, France
[2]PACA Regional Emergency Department Observatory, Ies-Sud, Hyères, France
[3]Regional office (Provence-Alpes-Côte d'Azur and Corsica), Santé Publique France, Marseille, France
[4]Data Science Division, Santé Publique France, Saint-Maurice, France
[5]Studies and Analysis, Federation of Observatories for Emergency Medecine, Hyères, France
Contact: gnoel@ies-sud.fr

Background:

Measles' outbreaks still occur in industrialised countries and reactive monitoring of the disease is needed. In France, measles' monitoring is based on a mandatory notification (MN).

Methods:

In France, for each emergency department (ED) visit, an Electronic ED Abstract (EEDA) is transmitted to the OSCOUR® network included in national Syndromic Surveillance System. EEDA include the diagnosis at discharge using International Classification of Disease (ICD-10). This study aims to evaluate the correlation between the number of measles MN and the number of ED visits related to measles and to calculate the positive predictive value (PPV) of diagnosis at discharge of measles in ED. The study period covered the third wave of the 2008-2011 French outbreak. From 2010 to 2011, we analyzed EEDA transmitted from 32/53 ED of the PACA region and regional measles MN. Using weekly aggregated data, the correlation between the number of measles cases given by both MN and ED sources was assessed (Pearson coefficient). In the 4 ED (2 pediatric) of the teaching hospital of Marseille, electronic medical files coded as measles were reviewed to evaluate the PPV of the diagnosis coded according to the national MN case definition (gold standard).

Results:

2,949 MN were transmitted and 1,306/1.3 million visits in ED were coded as measles. The peak of the outbreak was reported the same week by EEDA and MN. The correlation between EEDA and MN was strong (0.91; $p < 0.001$). Hospitalization rate was 20.7% and 21.0% according to EEDA and MN ($p = 0.81$). Among 363 medical files coded as measles in the 4 ED, 14 cases (3.9%) did not fulfilled the national case definition (PPV: 96.1 [IC95%: 94.2-98.1]), 86 (23.7%) fulfilled criteria for "clinical case" and 263 (72.5%) for "confirmed case".

Conclusions:

Most of the time, ED visits coded as measles fulfilled diagnosis criteria. Our results suggested that EEDA (better reactivity) could be complementary to MN (better completeness) to monitor measles.

Key messages:

- Most of the time, ED visits coded as measles fulfilled diagnosis criteria: PPV of coded medical diagnosis in ED for measles is high.
- Reactivity of ED data monitoring could usefully complete mandatory notification for measles surveillance.

Assessement of the influenza burden in nursing homes during two influenza seasons

Delphine Hequet

L Qalla-Widmer[1], *C Petignat*[1]
[1]Unité Cantonale HPCI, Lausanne, Switzerland
Contact: delphine.hequet@chuv.ch

Influenza is a significant cause of morbidity and mortality in elderly. They are at high risk of complications after influenza virus infection. Data on the epidemiology of influenza within nursing homes (NH) are limited. The purpose of this prospective study was to better describe the burden of influenza among residents of NH of canton of Vaud, Switzerland, with influenza-like illness during 2016-2017 and 2017-2018 influenza seasons. First, we determined the proportion of influenza-like illness due to influenza in NH residents. We specifically assessed the impact of a positive influenza PCR on clinical features, morbidity and mortality, 30 and 90 days after diagnosis, as compared to a negative influenza PCR. Moreover, influenza vaccination rates of the residents and the healthcare workers within each nursing home were assessed at the end of each influenza season. A PCR test was performed on 509 residents from 61 NH. 227 influenza virus infections were diagnosed; 181 influenza A and 46 influenza B. Compared to residents without influenza virus infection (IVI), residents with IVI were more often feverish with a high fever (69.1% and 88.5% respectively, $p < 0.0001$) are significantly more frequently hospitalized within 30 days after diagnosis (17.6% vs 7.1%, $p = 0.0003$). Any cause mortality at 30 days was similar in both groups (12.8% vs 10.6%, $p = 0.48$). Only 18.1% of IVI residents were treated with an antiviral and 60.4% of them received antibiotics. Influenza vaccination rates of the healthcare workers and residents were respectively 50% and 82%. During influenza season, the feverish residents should be suspected to have influenza virus infection. Residents should be diagnosed (PCR) and treated with an antiviral where appropriate to limit the risk of hospitalization. Healthcare workers should be encouraged to be vaccinated against influenza in order to acquire a better herd immunity within the NH which will limit the spread of influenza.

Key messages:

- Influenza virus in nursing homes is not treated enough.
- Influenza virus infection in nursing homes causes a high number of hospitalizations.

Characteristics of hospitalizations with influenza diagnosis, France, 2012-2017

Mathilde Pivette

M Pivette[1], *V de Lauzun*[1], *N Nicolay*[2], *A Scanff*[1], *B Hubert*[3]
[1]Cellule Bretagne, Santé Publique France, Rennes, France
[2]Cellule Normandie, Santé Publique France, Rouen, France
[3]Directions des Régions, Santé Publique France, Saint-Maurice, France
Contact: mathilde.pivette@santepubliquefrance.fr

Background:

Seasonal influenza surveillance in France is based on several data sources (ambulatory data, emergency department and intensive care unit (ICU) admissions, laboratory data, mortality). However, the data do not provide a complete measure of the impact of the epidemics on the hospital system. The objective of the study was to describe the characteristics of influenza hospitalizations from the French national hospital discharge database (PMSI) between 2012 and 2017 and to precise the burden of influenza by age group and by season.

Methods:

All hospitalizations in metropolitan France with at least one ICD-10 code related to influenza (J09, J10, J11) as a principal, related or associated diagnosis between 1 July 2012 to 30 June 2017 were extracted from the PMSI. For each season, the total number of hospitalizations, admissions to ICU, incidence and lethality rates, lengths of stay and classification in diagnosis-related groups were described by age group.

Results:

During the 5 seasons, 91 255 hospitalizations with an influenza-diagnosis were identified. The incidence varied significantly between seasons, from 12.7/100 000 in 2013-2014 to 45.9/100 000 in 2016-2017. A high number of cases was observed in elderlies in 2014-2015 and 2016-2017, marked by the circulation of A (H3N2) virus. The proportion of hospitalizations with an admission in ICU was 10%, and was higher in the 40-79 age group (19%). Lethality increased steadily with age, from 0.5% under 20 years to 10% in 80 years and older. Length of stay also increased with age. Significant regional disparities were observed, with higher incidence rates in South-Eastern France each season.

Conclusions:

The analysis of influenza hospitalizations from the PMSI provides important elements on influenza burden, not available in the current surveillance systems. An annual analysis, stratified by age group, would provide an indicator of the impact of the epidemics on hospital system at the end of each influenza season.

Key messages:

- Important influenza incidence variations were observed between seasons by age groups.
- Severity and impact of influenza (mortality, ICU, length of stay) varied significantly by age group.

Epidemiology of pertussis in Tunisia; results of five years 2013-2017

Hind Bouguerra

H Bouguerra[1], A Hechaichi[1], T Atawa[2], L Maazaoui[2], N Abdeddaiem[2], M Zorraga[2], M Sakly[2], N Ben Alaya[1,2]

[1]Epidemiology, National Observatory of New and Emerging Diseases, Ministry of Health, Tunis, Tunisia

[2]Publc Health, Primary Healthcare Direction, Minsitry of Health, Tunis, Tunisia

Contact: hind_296@hotmail.fr

Background:

Pertussis or whooping cough, is a highly contagious respiratory disease caused by a bacteria gram negative mainly Bordetella pertussis. It is globally endemic despite a high vaccination coverage. In 2014, the World Health Organization estimated the total number of affected persons to 16 million and the number of child deaths reached 190 000. Since 2012, many countries have experienced a resurgence of pertussis including Tunisia. Our objective was to describe the epidemiological situation of pertussis in Tunisia from 2013 to 2017.

Methods:

Our study was a retrospective descriptive study based on data of the surveillance system of Mandatory Reporting Diseases in Tunisia from 2013 to 2017. Data were collected using the declaration standardized forms which included in addition to the socio-demographic data, information regarding vaccination status, date of onset of symptoms and laboratory results (culture and PCR). Data entry was using EpiData and data analysis using SPSS-20.

Results:

During the study period, a total of 252 cases were notified. Males were more affected (55.1%). Age was in average 89 days (3 months). Almost the third were hospitalized in Intensive Care Unit (32.2%). Most cases were reported during 2013 and 2014 (35.7% et 55.5% respectively) and the lethality rate reached 7.2% in 2014. Half cases were notified in the Grand Tunis region. PCR was positive in 74.1% of the cases and bacterial culture was positive in 14.3%, isolating Bortedella pertussis. Vaccination status was mentioned in 70.5% of the cases: it was up-to-date in only 35.7% of the cases and incomplete in 9.8% of the cases.

Conclusions:

Our results showed that pertussis has known a considerable increase the last years, especially in 2013 and 2014. This prompts us to be more vigilant regarding this disease, which has been neglected the last decades. Education of population as well as health professionals is extremely important, particularly the importance of vaccination and preventive measures.

Key messages:

- From 2013 to 2017, number of pertussis cases in Tunisia varied with a considerable increase in 2013 and 2014.
- With the increase of pertussis cases and severity, preventive measures should be taken especially the importance of vaccination.

Prevalence and risk factors of hepatitis B in Tunisia

Aicha Lahchaichi

A Lahchaichi[1], M Ben Hadj[1], H Bouguerra[1], K Talmoudi[1], A Bahrini[1], O Bahri[3], H Letaief[1], O Hazgui[2], N Hannachi[2], N Ben Alaya Bouafif[1]

[1]National Observatory of New and Emerging Diseases, Tunis, Tunisia

[2]Laboratory of Microbiology, Farhat Hachad Hospital, Sousse, Tunisia

[3]Laboratory of Microbiology and Virology, Aziza Othmana Hospital, Tunis, Tunisia

Contact: aicha.hechaichi@gmail.com

Background:

Hepatitis B virus (HBV) infection is a major public health problem. Data related to epidemiology, distributions and outcomes of VHB infections in Tunisia remains scarce. This work aimed to study the prevalence of HBV infections and their distribution as well as the main risk factors associated to HBV infection.

Methods:

Our study was a cross-sectional household- based study carried out among a representative sample of 22 275 from January 2014 to December 2015. Sampling was based on the National Census of 2014. For data collection, questionnaires were administrated by trained investigator and blood samples were sent to the Reference laboratory for analysis of HBV markers.

Results:

Among 21720 surveyed subjects, 19663 subjects had a laboratory tests and the serological results reached to 19155. Overall prevalence of HBs Ag was 1.7% [1.6-1.9]. Prevalence of HBsAg was significantly higher in men (2.1% against 1.4%; $p < 10$-3), in age group more than 20 years (2.1% against 0.1% $p \ll 10$-3) and in the Central region (2.3%; $p < 10$-3). Among the associated risk factors in univariate analysis were chronic dialysis, dental care, surgical intervention, hospitalization, traditional circumcision, scarification and multiple sexual partners. Multivariate analysis showed that male gender, age over 20 years, center and south regions, hospital follow-up of a chronic pathology and having a family member chronic carrier of HBs Ag were the associated risk factors of HBV infection and vaccination was the only protective factor.

Conclusions:

Our study allowed to have a clear estimate of the national prevalence of HBsAg and to classify Tunisia as a country of low endemicity of Hepatitis B. This decline is mainly due to the introduction of vaccination since 1995 and the improvement of the health system. However, more efforts should be paid to reduce nosocomial transmission and traditional high-risk behaviors.

Key messages:

- Tunisia has become a country of low endemicity for hepatitis B.
- This was a result to the introduction of vaccination since 1995.

Human papillomavirus infections and cervical cancer screening in Tunisian women

Hind Bouguerra

H Bouguerra[1], A Hechaichi[1], H Letaief[1], M Ardhaoui[2], E Ennaiefer[2], S Bougatef[1], K Chahed[1], M Mechala[1], S Boubaker[2], N Ben Alaya[1]

[1]Epidemiology, National Observatory of New and Emerging Diseases, Ministry of Health, Tunis, Tunisia

[2]Human and Experimental Pathology, Pasteur Institute of Tunis, Tunis, Tunisia

Contact: hind_296@hotmail.fr

Background:

Human papillomavirus (HPV) infections are a significant public health problem with global estimations over 520 000 new cases and 274 000 deaths due to cervical cancer. In Tunisia, cervical cancer is the third cause of cancer in women but only a few prevalence studies conducted in specific populations are available. The present study aims to estimate the national prevalence of HPV infection and cervical cancer testing among Tunisian women.

Methods:

We conducted a population-based cross-sectional study in 2014. We included all sexually active women aged 18 years and older, present in primary health care centers the day of the study. Data collection was based on a standardized questionnaire including socio-demographic data, high-risk behaviors and previous cervical screening. HPV detection and typing was only done for betaglobin positive PCR-test. Ethical considerations were respected.

Results:

The total number of surveyed women was 1494 and the overall prevalence of HPV infection was 7.5% IC95% [5.9%-9.0%]. The most common genotypes were HPV6 (21.9%) and HPV16 (11.5%). Prevalence of high-risk HPV was higher than low-risk HPV; 4.8% IC95% [3.7%-6.2%] and 3.8% IC95% [2.8%-4.8%] respectively. The prevalence of previous cervical screening was 36.6% (95% CI [34.3%-39.2%]). This rate was significantly associated with age ($p < 10$-3); from 13.9% among those <30 years to 49.3% among those $\geq$ 50 years.

Conclusions:

Our survey provides an important overview of the current situation of HPV infection among Tunisian women. National prevalence of HPV infection was 7.5% but only 36.6% of women had a previous cervical cancer screening. This coverage remains poor, thus the need of targeted education and encouraging strategies to reduce cervical cancer burden in Tunisia.

Key messages:

- National prevalence of HPV infection is not negligeable in Tunisia, especially high risk HPV infections.
- Cervical screening is still low among Tunisian women, hence the need for education targeted to this population.

Invasive pneumococcal disease in Latvia seven years after PCV10 introduction

Larisa Savrasova

L Savrasova[1,5], *I Zeltina*[2], *A Villerusha*[3], *S Balasegaram*[4,5]
[1]Doctoral Studies Department, Riga Stradiņš University, Riga, Latvia
[2]Department of Infectology and Dermatology, Riga Stradins University, Riga, Latvia
[3]Department of Public Health and Epidemiology, Riga Stradins University, Riga, Latvia
[4]Field Epidemiology Service South East and London, Public Health England, London, UK
[5]European Programme for Intervention Epidemiology Training, European Centre for Disease Prevention and Control, Stocholm, Sweden
Contact: larisa.savrasova@gmail.com

Background:

In 2009 in Latvia, invasive pneumococcal disease (IPD) became notifiable for physicians and in 2010 vaccination of infants with PCV7 commenced. In 2012 PCV10 vaccination was introduced. The objectives of our study were to evaluate trend of incidence and trend serotype distribution of IPD in Latvia and to investigate factors associated with death from IPD.

Methods:

Laboratory confirmed IPD cases are passively notified to the Centre for Disease Prevention and Control of Latvia by laboratories and clinicians. We calculated incidence by age, sex, case fatality and trend in serotypes.

Results:

From 2012 to 2018, 466 cases of IPD were reported, mean annual incidence 3.4/100,000. The notified incidence remained stable from 2012-2014 (2.7), peaked in 2015 (4.4) and fell to 3.9 in 2018. The highest mean annual IPD incidence was in infants (4.8) and in elderly (6). The highest mean annual incidence was reported in males (4.5) in comparison to females (2.4) (IR-1.8 95%CI 1.6-2.4). Case fatality was 19% (87/466) and 23% (37/162) in cases aged > = 65 years. 90% (421/466) of isolates were serotyped. The proportion of PCV10 vaccine serotypes fell from 50% (20/40) in 2012 to 19% (14/74) in 2018 (chi2 test for trend = 0.000). Since year 2017, PPV23nonPCV13 and Non-vaccine serotypes become more common. We detected PCV13 serotype (RR 2.04 95%CI 1.37-3.02), S.pneumoniae serotype 3 (RR 1. 91 95% CI 1.25-2.93) significantly associated with IPD death.

Conclusions:

Surveillance data indicate evidence of serotype replacement. Surveillance evaluation should asses the representativeness of notification. Furthermore S. pneumoniae carriage study may be useful to characterise serotype circulation. Serotype 3 and age demonstrate independent and significant association with fatal IPD outcome.

Key messages:

- IPD surveillance data analysis indicated evidence of serotype replacement with PPV23nonPCV13, NonVaccine serotypes. Serotype 19A becomes more common with significant increasing trend.
- Serotype 3 and age independently and significantly associated with fatal IPD outcome. S.pneumoniae carriage study would be very useful providing more evidence of characterizing serotypes circulation.

Overview of three-year trends of antimicrobial consumption and resistance in Sicilian hospitals

Martina Barchitta

M Barchitta[1], *A Quattrocchi*[1], *A Maugeri*[1], *MC La Rosa*[1], *C La Mastra*[1], *L Sessa*[1], *P Cananzi*[2], *A Oteri*[2], *G Murolo*[2], *A Agodi*[1,3]
[1]Department GF Ingrassia, University of Catania - Dip GF Ingrassia, Catania, Italy
[2]Regional Health Authority, Sicilian Region, Italy
[3]AOU Policlinico-Vittorio Emanuele, Catania, Italy
Contact: martina.barchitta@unict.it

Background:

Antimicrobial resistance (AMR) is one of the ten threats identified by the WHO in 2019. In order to face this issue and in the framework of the National Action Plan on Antimicrobial Resistance (PNCAR) 2017-2020, the Sicilian Health Authority has implemented a surveillance system of antibiotic consumption in the hospital sector and in the community and of antibiotic resistance in the Sicilian hospitals. The aim of the present work is to report the results of three-year surveillance.

Methods:

From 2015 to 2017, data on antibiotic consumption have been collected from pharmacies of participating hospitals. AMR data on seven bacterial pathogens isolated in blood and cerebrospinal fluid have been collected from hospital laboratories, using routine clinical antimicrobial susceptibility tests. Antibiotic consumption was expressed as Defined Daily Dose (DDD) per 100 patient-days. Antibiotic resistance rates (RRs) were calculated as the number of non-susceptible isolates divided by the total number of isolates multiplied by 100.

Results:

The most commonly consumed antibiotics in participating hospitals were fluoroquinolones in 2015, penicillins in 2016, and beta-lactams in 2017, respectively. RRs of Klebsiella pneumoniae significantly increased for all antimicrobial classes ($p < 0.001$), but carbapenems. By contrast, RRs of Escherichia coli resistant to third-generation cephalosporins and carbapenems showed significant decreasing trends ($p < 0.001$).

Conclusions:

The implementation of the Sicilian surveillance system provides Sicilian reference data to monitor trends and target interventions and policies for reducing the threat of AMR. Recently, using toolkits of the ECDC-EAAD initiative adapted with regional surveillance data, an educational campaign "Obiettivo Antibiotico" - https://www.obiettivoantibiotico.it/ - was designed and launched to raise awareness of prudent use of antibiotics in the general public and in healthcare professionals in Sicily.

Key messages:

- Inappropriate antimicrobial consumption observed in Sicilian hospitals contributes to the emergence and selection of AMR.
- Surveillance system of antimicrobial consumption and AMR can help identify strategies for preventing spread of multi-drug resistant microorganisms.

Community use of antibiotics and development of bacterial resistance: a case-control study in Italy

Gianluigi Ferrante

G Ferrante[1], *M Massari*[1], *R Da Cas*[1], *A Pantosti*[1], *P Pezzotti*[1], *V Moser*[2], *E Pagani*[2], *R Aschbacher*[2], *G Traversa*[1]
[1]Italian National Institute of Health, Rome, Italy
[2]Health District of Bolzano, Bolzano, Italy
Contact: gianluigi.ferrante@iss.it

Background:

Antibiotic resistance is now a global emergency. An increasing number of infections are becoming difficult to treat and lead to longer hospitalizations, higher medical costs and increased mortality. The aim of this study is to assess, in a population at low prevalence of use of antibiotics, whether a previous use of these drugs is associated with the occurrence of clinically relevant resistance of E.coli to fluoroquinolones (FQs), one of the most widespread and critical bacteria resistance in Italy.

Methods:

Through a data linkage of databases of the health information systems of the Province of Bolzano (Italy) a case-control study was carried out using 2016 data. All subjects for which the resistance of E. coli to FQs was tested by the regional microbiology reference laboratory were included in the study. Those with a positive FQs-resistant E.coli isolate were defined as cases (n = 409), while the others were considered controls (n = 933). For each subject the total number of prescriptions of any antibiotics and the total number of prescriptions of FQs in the previous year were detected through a record linkage with the drug prescription database. Information on potential confounding factors (age, gender, number of hospital admissions, days of hospitalization, number of surgeries, diagnosis of chronic diseases) were obtained from the database of hospital admissions. Multivariate logistic regression analysis was used to study the association between previous use of antibiotics (any and FQs only) and development of E.coli resistance to FQs.

Results:

It was observed that for each unit increase in the number of prescriptions of any antibiotic, the probability for E.coli to develop FQs resistance significantly rises by 16%. This probability is much higher (45%) if the prescribed antibiotic is a FQ.

Conclusions:

This study confirms the association between previous consumption of antibiotics and the onset of resistance even in an area with a low prevalence of use.

Key messages:

- The results of this study reiterate the need to prescribe and dispense antibiotics only when they are really needed.
- Health information systems allows to study the role of antibiotic use in the development of bacterial resistance, providing useful information for audit interventions among healthcare professionals.

4.S. Health outcomes and social determinants

Changes in disease burden in Poland, 1990-2017: a systematic analysis for the GBD Study 2017

Maria Ganczak

M Ganczak[1], T Miazgowski[2], M Kozybska[3], A Kotwas[3], M Korzeń[4], B Rudnicki[5], T Nogal[5], J Kopec[6]

[1]Department of Epidemiology and Management, Pomeranian Medical University, Szczecin, Poland
[2]Department of Hypertension & Internal Medicine, Pomeranian Medical University, Szczecin, Poland
[3]Department of Public Health, Pomeranian Medical University, Szczecin, Poland
[4]Department of Methods of Artificial Intelligence and Applied, West Pomeranian University of Technology, Szczecin, Poland
[5]Healthcare Management and Administration student, Pomeranian Medical University, Szczecin, Poland
[6]Division of Epidemiology, Biostatistics and Public Health Pr, School of Population and Public Health, Vancouver, Canada
Contact: ganczak2@wp.pl

Background:

In Poland, a comprehensive analysis describing trends in disease burden for major conditions has never been published. The study objective was to use the GBD database to assess disease burden in Poland, evaluate changes in population health between 1990-2017, and compare Poland with other Central European (CE) countries.

Methods:

The results of GBD 2017 for 1990 and 2017 for Poland were used to assess rates and trends in years YLLs, YLDs, DALYs.

Results:

Between 1990 and 2017, age-standardized YLL rates for all causes declined in Poland by 46.0%, YLD rates declined by 4.0%, and DALY rates by 31.7%. Greater relative declines were observed for females regarding YLLs/YLDs. There was a decrease in communicable, maternal, neonatal and nutritional disease DALYs (48.2%); DALYs due to non-communicable diseases (NCDs) decreased 2.0%. In 2017, Poland performed better than CE as a whole (ranked 4th for YLLs, 6th for YLDs and 5th for DALYs) and achieved greater reductions in YLLs and DALYs than most CE countries. In both 2017 and 1990, the leading cause of YLLs and DALYs in Poland was ischemic heart disease (IHD), of YLDs - low back pain. In 2017, the top 20 causes of YLLs and YLDs in Poland and CE were the same, although the order was different. In Poland, age-standardized DALYs from neonatal causes, other cardiovascular and circulatory diseases, and road injuries declined substantially between 1990 and 2017, while alcohol use disorders and chronic liver diseases increased. The highest observed-to-expected ratios (OER) were seen for alcohol use disorders for YLLs, neonatal sepsis for YLDs, and falls for DALYs (3.21, 2.65 and 2.03 respectively).

Conclusions:

Improvement in Health in Poland has been observed since 1990. In 2017 the country outperformed CE as a whole for YLLs, YLDs and DALYs. While the health gap between Poland and Western Europe has diminished, it remains substantial. IHD is still the leading cause of disease burden in Poland, but DALYs from IHD are declining.

Key messages:

- In the light of dramatic shortage/aging of the workforce and low public health expenditure, the observed rise in NCDs and between-gender inequalities pose a challenge for the Polish health-care system.
- To minimize the gap between Poland and Western Europe, an integrated response, which addresses the causes of death and ill-health, particularly those for which rates have increased, is urgently needed.

Daylight saving time and acute myocardial infarction: a meta-analysis

Maria Elena Flacco

L Manzoli[1], ME Flacco[2], F Bravi[3], T Carradori[3], R Cappadona[4], F Fabbian[4], A De Giorgi[4], R Manfredini[4]

[1]University of Ferrara, Ferrara, Italy
[2]Regional Healthcare Agency of Abruzzo, Pescara, Italy
[3]Azienda Ospedaliero Universitaria 'S. Anna', Ferrara, Italy
[4]Faculty of Medicine, Surgery and Prevention, Ferrara, Italy
Contact: elena.flacco@gmail.com

Background:

The current evidence on the effects of daylight saving time (DST) transitions on major cardiovascular diseases is limited, and available results are conflicting. We carried out the first meta-analysis aimed at evaluating the risk of acute myocardial infarction (AMI) following DST transitions.

Methods:

We searched MedLine and Scopus up to December 31, 2018, with no language restriction, to retrieve cohort or case-control studies evaluating AMI incidence among adults ($\geq$18y) in the week following spring and/or autumn DST shifts versus control periods. A summary relative risk of AMI was computed after: (1) spring, (2) autumn, (3) both transitions considered together versus control weeks. Stratified analyses were performed by gender and age. Data were combined using a generic inverse-variance approach.

Results:

Seven studies (>115,000 subjects) were included in the analyses. A significantly higher risk of AMI (Odds Ratio: 1.03; 95% CI: 1.01-1.06) was observed in the two weeks following spring or winter DST transitions. The risk increase was however significant only after the spring shift (OR: 1.05; 1.02-1.07), while AMI incidence in the week after winter DST transition was comparable to control periods (OR 1.01; 0.98-1.04). No substantial differences by age or gender emerged.

Conclusions:

The risk of AMI increases modestly but significantly following DST transitions, supporting the proposal of DST shifts discontinuation. Additional studies fully adjusting for potential confounders are required to confirm the present findings.

Key messages:

- The risk of acute myocardial infarction increases modestly but significantly following DST transitions.
- Although preliminary, our findings support the proposal of DST shifts discontinuation.

Association of nationality and education with oral health: a screening programme in Northern Italy

Massimo Del Pin

M Del Pin[1], G Varadi[1], S Pascut[2], R Tito[3], A Dovier[3], C Covre[1], F Honsell[4], F Valent[5], M Parpinel[1], S Brusaferro[1,3]
[1]Department of Medicine, Università degli Studi di Udine, Udine, Italy
[2]Healthy Cities Project, Udine, Italy
[3]Udine Healthcare and University Integrated Trust, Udine, Italy
[4]Università degli Studi di Udine, Udine, Italy
[5]Institute of Hygiene and Clinical Epidemiology, Udine Healthcare and University Integrated Trust, Udine, Italy
Contact: delpin.massimo@spes.uniud.it

Background:

Socioeconomic status (SES) has been proposed as an important determinant of oral health outcomes. The aim of this project is to assess the association between nationality, parents' educational level and oral health in a sample of children in Udine, Italy.

Methods:

Between February and May 2018, in the context of a screening programme carried out to evaluate the oral health status in 6-year-old children, parents filled out a questionnaire investigating behavioural, socioeconomic and demographical factors. For each child the number of decayed, missing and filled deciduous teeth (dmft) and caries prevalence (CP) were assessed.

Results:

The screening was conducted on 976 children, 705 (72%) Italian (I) and 271 (28%) foreign residents (F). Not-Italian nationality significantly increased the CP (F: 59.32%; I: 32.74%; RR: 1.81 [95% CI: 1.57-2.10]; Risk Difference: 26.59 [95% CI: 19.98-33.19]) and dmft median value (F: 2±5; I:0±1; $p<0.0001$). Stratified by level of education, the differences between I and F were significant when both parents had low educational level (CP: RR = 1.62 [95%; CI: 1.00-2.62]; dmft: F = 5±5; I = 0±3; $p<0.05$) and when both parents had high school education (CP: RR = 1.45 [95%; CI: 1.14-1.84]; dmft: F = 2±6; I = 0±2; $p<0.001$). Otherwise, when both parents had university degree, nationality did not increase significantly the outcome (CP: RR = 1.17 [95%; CI: 0.91-1.50; $p>0.1$]; dmft: F = 0±2; I = 0±0; $p>0.1$).

Conclusions:

The analyses suggest that being a foreign resident is a risk factor for lower child oral health. Moreover, parents' educational level seems to be an effect modifier: when parents had a university degree there was no significant difference between Italians and foreign residents, otherwise the lower the level of education, the greater the difference between the categories. These data may help to identify particularly vulnerable groups and to develop preventive strategies.

Key messages:

- These findings confirmed the presence of a vulnerable population (foreign residents) in which socioeconomic factors had stronger associations to oral health than Italian citizens.
- Further research may be useful to identify both protective and risk factors associated with different nationality, in order to evaluate specific interventions in low-SES groups.

Monitoring inequalities in self-rated health over 36 years among Finnish women and men

Eero Lahelma

E Lahelma[1], O Pietiläinen[1], O Pentala-Nikulainen[2], S Helakorpi[3], O Rahkonen[1]
[1]Department of Public Health, University of Helsinki, Helsinki, Finland
[2]Statistics Finland, Statistics Finland, Helsinki, Finland
[3]National Institute for Health and Welfare, Helsinki, Finland
Contact: eero.lahelma@helsinki.fi

Background:

Health inequalities across countries and populations are well established, but little is known about their long-term trends and even less about factors shaping the trends. We examined the magnitude of absolute and relative educational inequalities in self-rated health over 36 years among adult Finns, considering individual covariates and macro-economic fluctuations.

Methods:

Data were derived from representative annual surveys in 1979-2014 among men and women and covered ages 25-64. Nine periods were used (n = 8870-14235). Our health outcome was less-than-good self-rated health and our socioeconomic indicator was completed years of education as a continuous variable. Nine time-variant sociodemographic and health-related covariates were included. Educational inequalities in self-rated health were examined by relative index of inequality (RII) and slope index of inequality (SII).

Results:

Linear trends suggested stable overall development in both relative and absolute health equalities during 36 years. Period specific analyses showed that among men relative and absolute inequalities narrowed immediately after economic recession in Finland in 1993-94, and among women, inequalities narrowed during global financial crisis in 2008-09. Adjusting for covariates reduced the magnitude of inequalities throughout the nine periods, but affected little the period specific patterning of health inequalities.

Conclusions:

Educational inequalities in self-rated health persisted during 36 years in Finland. While among men and women health inequalities narrowed during and after recessions, they widened soon back to the pre-recession level. The perseverance calls for powerful measures to tackle health inequalities, such as preventing unhealthy behaviours, obesity and unemployment in particular among the lower educated.

Key messages:

- Health inequalities have persisted in Finland over 36 years, with unhealthy behaviors and unemployment affecting their magnitude.
- Health inequalities narrowed during economic recessions, but widened soon back to pre-recession level.

Welfare state impact on mental wellbeing of the oldest old in Europe: A multilevel survey data study

Jorid Kalseth

J Kalseth[1]
[1]Health Research, SINTEF Digital, Trondheim, Norway
Contact: jorid.kalseth@sintef.no

Background:

Improving the health and wellbeing of the oldest old population is a key public health policy concern considering the rapid aging of the world's population. The purpose of this study was to investigate the impact of the welfare state on different aspects of mental wellbeing of the oldest old population in Europe. Several approaches to measure welfare state types were compared.

Methods:

The study used individual level data from Round 6 of the European Social Survey to measure six dimensions of mental wellbeing among the 80+ population including countries belonging to the European Union or European Economic Area. Welfare state types were measured using one welfare state- and three elderly care regime typologies, as well as three welfare state dimensions based on factor analyses of several welfare state characteristics. Welfare state impact on mental wellbeing was analysed by multilevel regression analyses, controlling for age and gender.

Results:

The preliminary results show that universalistic and service-based regimes, as e.g. Nordic countries, are associated with higher level of subjective wellbeing and social trust, but not psychological wellbeing, compared to family-based regimes with low formal support. East Europe have lower scores on all dimensions compared to Nordic countries. The welfare state dimension capturing prioritisation of health and social services and gender equality is positively associated with all wellbeing aspects, whereas the factors capturing labour market participation of seniors and income equality respectively, are only significantly associated with subjective wellbeing and social trust.

Conclusions:

The result point to caring approaches with high level of formal support and gender equalisation as key to enhance all aspects of mental wellbeing for the oldest old. Stimulating long duration of working life and reducing income inequalities have the potential to increase life satisfaction and happiness and social trust.

Key messages:

- Welfare state matter for the mental wellbeing in the oldest old population.
- General measures, supporting formal care, labour market participation and income and gender equality will also benefit the oldest old.

Changes in mortality inequalities by marital status in Lithuania during 2001-2014

Skirmante Sauliune

S Sauliune[1], O Mesceriakova-Veliuliene[1], R Kalediene[1]
[1]Department of Health Management, Lithuanian University of Health Sciences, Kaunas, Lithuania
Contact: skirmante.sauliune@gmail.com

Introduction:

Health inequalities have emerged as a big issue of public health in Lithuania. Recent studies have demonstrated increasing mortality differentials between marital status groups, occurring mainly due to a decline in mortality of the married populations.

The aim of the study - to determine changes in inequalities in mortality from major causes of death by marital status in Lithuania during 2001-2014.

Methods:

Individual records from population censuses conducted in 2001 and 2011, National Mortality Register (period of 2001-2014), and Population Register (period of 2001-2014) have been linked using personal identification number. Study included those aged 30+. Mortality rates from cardiovascular diseases, cancer, external causes and digestion system diseases by the marital status (married and unmarried - never married, the widowed and the divorced) were calculated per 100 000 person years and standardized by age. Inequalities in mortality were assessed calculating rate ratio, while trends in it - conducting the Joinpoint regression analysis.

Results:

Mortality from all analyzed causes of death among males and females in 2001 and 2014 was statistically significantly higher in unmarried compared to married. Inequalities in mortality by marital status increased statistically significantly in Lithuania throughout the period of 2001-2014 from cardiovascular diseases, cancer and external causes. The most significant increase in inequalities by 3.3% ($p < 0.05$) on average per year was estimated from external causes among males. Inequalities in mortality from digestion system diseases did not change significantly throughout the study period.

Conclusions:

Inequalities in mortality by marital status increased significantly in Lithuania throughout the period of 2001-2014 with the most significant increase from external causes.

Key messages:

- Mortality from all analyzed causes of death among Lithuanian males and females in 2001 and 2014 was statistically significantly higher in unmarried compared to married.
- Inequalities in mortality by marital status increased significantly in Lithuania throughout the period of 2001-2014 with the most significant increase from external causes.

Public health monitoring in Sweden focusing on inequality – a developmental work

Karin Engström

K Engström[1], M Makenzius[1], G Olsson[1], N Lindqvist[1]
[1]Public Health Reporting, The Public Health Agency of Sweden, Solna/Östersund, Sweden
Contact: karin.engstrom@folkhalsomyndigheten.se

Issue/problem:

The overarching goal of the Swedish public health policy is to create the right societal conditions for good and equitable health throughout the population, and to reduce avoidable health inequalities within a generation. Relevant health topics and dimensions of inequalities in health should be monitored to enable effective interventions on the local, regional and national level. To achieve this a strong national health monitoring system (HMS) is central.

Description of the problem:

The objective was to develop a high quality HMS to monitor a broad perspective of public health and its determinants, complemented by a more focused monitoring system of inequalities in health, with relevance on the local, regional and national level. A theoretical framework was developed and empirical mapping of relevant indicators conducted. An expert group was consulted and a country assessment of how to monitor health inequalities was carried out within the Joint action Health Equity Europe project. The developmental work started in 2018 and is not yet completed.

Results:

A web-based monitoring system has been implemented to cover the broad perspective of public health and its determinants. All indicators are reported at the national level and, when possible, degradable at the local and regional level. In addition, a report with a focus on inequalities in health on a national level is published annually, and a longitudinal indicator-based comparative study, with results from Sweden's 21 regions and 290 municipalities was published in 2019.

Lessons:

General public health and inequalities in health may need to be monitored in different ways. To enable effective interventions, consideration must be given to at what level - local, regional or national - policy decisions are made.

Key messages:

- High quality health monitoring enables effective interventions.
- To reduce inequalities in health focused monitoring is required.

Development of a barometer to display and monitor health and wellbeing on the neighborhood level

Kristina Hoffmann

J Hilger-Kolb[1], H Röhrbein[1], H Kairies[2], K Heinrich[2], K Hoffmann[1]
[1]Heidelberg University, Mannheim Institute of Public Health, Social and Preventive Medicine, Medical Faculty Mannheim, Mannheim, Germany
[2]Jugendamt und Gesundheitsamt, Referat Jugendhilfeplanung und Gesundheitsplanung, Stadt Mannheim, Mannheim, Germany
Contact: kristina.hoffmann@medma.uni-heidelberg.de

Background:

Neighborhoods and their characteristics play a key role for establishing and maintaining health and wellbeing of their residents. However, before programs promoting health and wellbeing in the neighborhood can be planned and implemented, it is necessary to identify local needs for action. This is especially important for the stakeholders that work in the neighborhood (e.g., employees of the local community, headmasters of schools). We thus developed exemplary for Herzogenried -a neighborhood in the German city of Mannheim- a barometer that aims to assess and monitor health and wellbeing in the neighborhood and indicates potential needs for action.

Methods:

We conducted a detailed literature search to identify indicators that were associated with health and wellbeing in neighborhoods. Based on the search we created a primary list of indicators, which we presented and discussed during 15 meetings with a total of 26 different stakeholders. Available data on the indicators agreed on were checked for accuracy, statistically processed, and visualized for incorporation into the barometer.

Results:

The barometer consists of the following eight dimensions which in total include 80 indicators: population structure, population development, household structure, material wellbeing, education, family and upbringing, health, and personal security. The barometer also includes a map that displays structural characteristics of the neighborhood such as physicians, schools, supermarkets. An important challenge we faced was the availability of indicators as some of them were only accessible at the community level or for specific age groups.

Conclusions:

The barometer offers a comprehensive overview on the neighborhood, provides first hints for the local stakeholders on needs for action, and helps to prioritize the issues that should be addressed to promote health and wellbeing in Herzogenried. It will also serve as a prototype for other neighborhoods in the future.

Key messages:

- The barometer was planned to serve as a transferable tool to identify and prioritize action steps for neighborhood development and to help promoting health and wellbeing of their residents.
- As the barometer displays indicators relevant for various community stakeholders it can serve to identify joint goals and thus foster stronger trans-sectoral collaboration at the neighborhood level.

The applicability of methods for assessing comorbidities: The Cumulative Illness Rating Scale (CIRS)

Margherita Napolitani

M Napolitani[1], L Kundisova[1], G Messina[2,1], N Nante[2,1]

[1]Post Graduate School of Public Health, Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy

[2]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy

Contact: napolitani1005@hotmail.it

Introduction:

It is essential to compare the results of medical care in patients suffering from multiple, and complex diseases. CIRS is a risk adjustment tool useful for assessing patients' comorbidities although it needs to be used with precision following guidelines. The aim of this research is to assess whether organised seminars, planned to motivate the clinicians for correct data compilation, have an effect on the concordance of scores on the CIRS scores.

Methods:

A prospective, pilot study started in November 2018 on a sample of 49 patients admitted to a private clinic between December 2018 and February 2019. In the context of a seminar, an Resident Physician in Public Health (RP), distributed and explained the CIRS guidelines to the clinicians. CIRS scores were then calculated by the ward physicians and compared with those of the RP who successively analysed the same medical records. The inter-rater agreement was calculated through Cohen's kappa coefficient (κ), using Stata 14.2.

Results:

Concordance was excellent or almost perfect or substantial for 8 out of 14 categories: heart disease (k = 0.82), genitourinary disease (k = 0.90) blood pressure category (p = 0.72), sense organs (k = 0.75), upper gastrointestinal system (k = 0.70), lower gastrointestinal system (k = 0.76), musculoskeletal system and skin (k = 0.66), central nervous system (k = 0.69), endocrine system and breast (k = 0.63) and psychiatric diseases (k = 0.63). The agreement was moderate for the respiratory system (k = 0.48) and for the liver (k = 0.57), and was fair for Severity Index, Comorbidity Index and the vascular system (k = 0.24, k = 0.38 and k = 0.28 respectively).No Concordance in renal diseases (k = 0.00).

Conclusions:

Overall, the agreement of the scores between RP and clinicians was good, and it was possible to analyse the main weaknesses and difficulties of the clinicians. Subsequent seminars will be done to increase over time the concordance of the surveys.

Key messages:

- Organized seminars, planned to motivate clinicians to correctly compile the CIRS scores, were effective.
- The inter-rater agreement was good. Subsequent seminars will be done to increase over time the concordance of the surveys.

Population health indicators availability at regional level across the European Union

Claudia Costa

C Costa[1], A Freitas[1], P Santana[1,2]

[1]Centre of Studies in Geography and Spatial Planning, University of Coimbra, Coimbra, Portugal

[2]Department of Geography and Tourism, University of Coimbra, Coimbra, Portugal

Contact: claudiampcosta@gmail.com

Background:

The availability of reliable and comparable data at the regional level is extremely important to measure regional health inequalities. The aim of this research is to assess the data availability of the indicators included in EURO-HEALTHY's Population Health Index (PHI), a multidimensional tool developed to measure population health across European regions.

Methods:

Three consecutive steps where implemented: i) assessment of data availability and reliability of the indicators for the regional level and for the last year with data available; ii) application of a protocol to solve cases of missing data and assure the database completeness and iii) development of an availability scoring system, ranging from 0 (no data available) to 1 (all data available), by indicator and EU region.

Results:

A set of 39 population health indicators were assessed. The mean availability is 0.8, ranging from 0.46 (worst) to 1 (best). Indicators such as 'Unemployment', 'Higher education', 'Ageing index', 'Teenage motherhood', 'Victims in road accidents', 'Fatality rate', 'Life expectancy' and 'Infant mortality' present the highest scores (>0.95). 'Daily smokers', 'Pure alcohol consumption', 'Number of rooms per person' and access to 'Public water supply' and 'Wastewater treatment' present the lowest availability scores (<0.60), mostly due to the availability at the national level only.

Conclusions:

This study provides a comprehensive assessment of data availability of population health indicators from multiple areas of concern, at the EU regional level. The results highlight the urgent need for sub-national data in several domains that are important to close the health gap between and within countries. Still, as data collection in EU is driven by a policy derived framework, it is essential to give awareness to the regional scale, prior to the policy development.

Key messages:

- There is an urgent need for sub-national data in several domains that are important to close the health gap between and within countries.
- As data collection in EU is driven by a policy derived framework, it is essential to give awareness to the regional scale, prior to the policy development.

How to build and share an experiential knowledge in public health?

Anne Laurent

A Laurent[1], C Ferron[2], P Lombrail[1], P Berry[3], MO Frattini[4], F Berdougo[1], E Rusch[1]
[1]SFSP, Laxou, France
[2]FNES, Paris, France
[3]Nantes, France
[4]Promo Santé Ile de France, Paris, France
Contact: anne.laurent@sfsp.fr

Health promotion stakeholders are encouraged to base their intervention strategies on evidence. However, the evidence produced by public health research is outcome-based and provides little information on ‘‘how to act?’’ It is necessary to complete this evidence with experiential data constituting an evidence of a different nature, answering questions about organizations, skills and tools mobilized to achieve the results, and valuing skilled actors' knowledge and good practice.

For two years, a group of 15 French organizations has been working on capitalization and sharing experiential knowledge. This work is part of the setting up of a national evidence platform. After a benchmarking phase, the group developed and tested a capitalization method which focuses on the collection and analysis of qualitative data and aims to explain the contexts and processes at work in the actions: knowledge and skills, strategies, perceived challenges and facilitating factors, key moments. The group also worked on the structure, content and use of a shareable document.

The test has shown the pedagogical interest of the method for the actors who were invited to develop a reflective thinking about their action, as well as the relevance of this method to build experiential knowledge. The ongoing group's work concerns the dissemination of collected data. A practical guide for stakeholders is being finalised. The group is defining the selection process of the initiatives to be valued, in particular with regard to results that make sense for all stakeholders.

The main difficulty of the approach - its low level of recognition and entrenchment in public health - will be discussed during the presentation, as well as the necessity to ensure the legitimacy of this approach in a context where the notion of evidence is centered on quantitative data produced with an objective defined ‘‘a priori’’ and in a controlled context.

Key messages:

- This work opens the way for an original reflection in public health to build a shareable experiential knowledge, and to valorize and strengthen field actors' practical expertise.
- This work has pedagogical, political, scientific and informational impacts. It contributes to knowledge transfer and provides self-training, a practical vision of policies, and questions for research.

5.R. Digital health and social media

Commuter e-bike use is associated with increased total physical activity over time

Bruno Chabanas

B Chabanas[1,2], C Praznoczy[2], M Duclos[1,2]
[1]CHU Clermont-Ferrand, Clermont Ferrand, France
[2]ONAPS, Clermont Ferrand, France
Contact: bruno.chabanas@uca.fr

Background:

Active commuting such as cycling has been recommended as a practical way to increase population physical activity levels and improve health. Beside positive health effects observed in experimental studies, less is known about how e-bikes can improve public health outcomes in real-life settings.

Objectives:

To describe the patterns over time in physical activity, sedentary behavior, cardiorespiratory fitness and psychophysiological well-being in a population of new commuter e-bike users.

Methods:

This was a population-based prospective longitudinal study in France. 33 new users of e-bike were recruited and measured at 4-time points (T0, T1, T2, T3), from before the effective beginning of the e-bike use (T0) until a mean of 4.6 months of use (T3) (min: 3.2, max: 7). Repeated measures multilevel modeling was used on 4 waves of measurements to assess variations over time of e-bike use, total moderate and vigorous physical activity (MVPA) and total sedentary time (SED-time). Pre-post comparisons between T0 and T3 were performed to detect change in cardiorespiratory fitness, markers of adiposity, self-esteem, quality of life (SF12-v2), and physical activity motivations (EMAPS).

Results:

Adherence to e-bike commuting was high and stable, with a mean of 82% (3%) of weekly use. Multilevel modeling indicated that MVPA followed a significant increasing curvilinear trajectory over time, plateauing after 90 days (+ 21 MET-h/week compared to mean T0 at 33 MET-h/week). No significant change was found in SED-time, averaging a mean of 8.6 hours/day. Greater adherence to using an e-bike was associated with greater increases in MVPA. Several markers of physical and mental health improved.

Conclusions:

New commuter e-bike users undergo a significant increase in MVPA while being already at a high level before e-bike use onset. This increase in MVPA could be meaningful to attenuate detrimental effects of a persistent high sedentary behavior.

Key messages:

- MVPA significantly increases among new commuter e-bike users, along with improvements in physical and mental health.
- High SED-time is persistent, making increase in MVPA in a population with a moderately high initial level still crucial.

Using e-health to shorten treatment delay in patients with severe aortic stenosis

Morgane Michel

M Michel[1,2], J Hammami[1,2], MA Vinet[1,2], C Picot-Ngo[2], NA STOP-AS Investigators, F Debroucker[3], M Gilard[4], K Chevreul[1,2]
[1]URC Eco, Assistance Publique-Hôpitaux de Paris, Paris, France
[2]UMR 1123, INSERM, Université de Paris, Paris, France
[3]Économie de la Santé & Remboursement, Medtronic France SAS, Boulogne-Billancourt, France
[4]Department of Cardiology, University Hospital of Brest, Brest, France
Contact: morgane.michel@urc-eco.fr

Background:

Transcatheter aortic valve replacement (TAVR) is a relatively new alternative to open surgery in patients with a severe aortic stenosis at high risk of surgery but there are important variations in treatment delay which can lead to increased morbidity and mortality. Those delays have many causes, including patients' unawareness of the urgency, delays in obtaining the necessary preoperative tests and organizational factors at the hospital level. The aim of our study was to co-construct an e-health tool for patients and their families to empower them and improve knowledge on the disease and TAVR to ultimately decrease the delay between the medical decision for TAVR and the actual procedure.

Methods:

A prospective study was first carried out to identify organizational factors associated with variations in treatment delay (both at the patient and hospital level). A preliminary survey was sent to all TAVR centers in France to understand and describe their organization. Descriptive analyses were then carried out on the answers. In a second step, two focus groups were carried with, the first with patients and carers and the second with healthcare professionals in order to elaborate the e-health tool.

Results:

A website has been developed for patients and their families. It includes information in video form on aortic stenosis and its different treatments, on TAVR, the necessary tests required prior to TAVR (with a geolocalisation of available facilities nearby so that patients may know where to go), and what they can expect during the hospital admission and after their release. Patients undergoing TAVR will be informed of the website's existence by their cardiologist. Web pages intended for healthcare professionals who are not TAVR specialists (general practitioners…) will also be available on the website.

Conclusions:

A cluster randomized controlled trial will now test the efficacy and efficiency of the e-health tool in reducing TAVR treatment delay.

Key messages:

- We built a e-health tool in collaboration with patients, carers and healthcare professionals to increase patients' knowledge on aortic stenosis and TAVR.
- The website will provide information through videos to empower patients and ultimately decrease treatment delay and its associated morbi-mortality.

The use of digital devices in the field of healthcare in Bulgaria

Kristina Kilova

K Kilova[1], *D Milkov*[2], *N Mateva*[1]

[1]Department of Medical Informatics, Biostatistics and e-Learn, Faculty of Public Health, Medical University of Plovdiv, Plovdiv, Bulgaria

[2]Faculty of Public Health, Medical University of Plovdiv, Plovdiv, Bulgaria

Contact: k_kilova@yahoo.com

Background:

The opportunities that information and communication technologies provide in the field of healthcare are many and constantly growing. Thanks to them, consumers have access to health information, consultations and remote treatment and connection with medical centers. They help to improve health promotion activities, whose mission is to promote health as a core value. The aim of the present study is to explore the attitudes regarding the use of digital devices in the field of healthcare of Bulgarian population.

Methods:

A direct anonymous survey was conducted among 356 respondents, randomly selected and with an average age of 38.26 ± 0.15 (110 men and 246 women). The study was conducted from October 2018 to April 2019. The data analysis was performed using the statistical software SPSS v.23.0.

Results:

The results showed that 78.9% of respondents have used or are willing to use digital devices to search for and record health information. A statistical gender difference was found in the answer to the question of using a digital device for self-registration of information ($\chi2 = 28.6$, $P < 0.05$), as women are more likely to do so. More than 75% of respondents are willing to share health information with a medical professional in real-time via the internet. Older people are more reserved and hesitant about providing health information to a state agency (66.7%). The smartphone and computer/laptop are among the most preferred digital modalities in the healthcare field, with men and younger respondents more likely to use digital devices in relation to their health ($\chi2 = 39.9$, $P < 0.05$). Women are more critical about the use of information and communication technologies in healthcare ($\chi2 = 48.2$, $P < 0.05$).

Conclusions:

The present study found a positive attitude among all respondents towards the introduction of modern technologies in the healthcare field and the opportunity of remote contact with medical professionals, using personal digital devices.

Key messages:

- The opportunities that information and communication technologies provide in the field of healthcare are many and constantly growing.
- The aim of the present study is to explore the attitudes regarding the use of digital devices in the field of healthcare of Bulgarian population.

Assessment of the e-health system in the Kaunas City Outpatient Clinic

Snieguole Kaseliene

S Kaseliene[1], *L Blazeviciute*[1], *O Mesceriakova-Veliuliene*[1]

[1]Department of Health Management, Lithuanian University of Health Sciences, Kaunas, Lithuania

Contact: skaseliene@gmail.com

Background:

The Lithuanian National Electronic Health (e-health) System was only launched in 2015. The aim of this study is to evaluate the e-health system in the Kaunas City Outpatient Clinic using a system of balanced performance indicators.

Methodology:

The survey was carried out from October until December, 2018, at the Kaunas City Outpatient Clinic (Lithuania). The study included 264 medical staff members and 384 patients.

Results:

62% of the patients and 100% medical staff of the clinic used various e-health system services. The most often used services by the patients were SMS reminder (75.5%), online registration (70.8%) and electronic prescription (59.3%). The physicians took the most advantage of assigning electronic prescriptions (88.2%), filling the sickness certificates (78.9%), booking laboratory tests and receiving their results electronically (63.9%). Majority of the medical staff and patients stated that the e-health services are of high quality (77.6 and 89.5%, respectively), reliable (86 and 90.8%) and have a wide spectrum of services (75.3 and 93.7%). The most common problems that patients faced when using the e-health system services were the malfunctions and failures of the system (68.9%) or missing health data of the patient (59.7%). According to the medical staff, e-health system technologies do not cover the needs of employees in full extent (95.1%), also, the e-health system is still not completely reliable (97.7%). Only 56.7% specialists stated, that they have enough skills to work with the e-health system, 77.7% would like to improve their professional qualifications in this field. The Clinic used the funds of the institution, municipality or EU structural funds to develop the e-health system, update the computer equipment and software, and acquire licenses.

Conclusions:

More efficient and effective e-health services and developing the capacity of the e-health usage are required to promote high-quality health care in Lithuania.

Key messages:

- Although majority of the patients and medical staff members use various e-health system services and are satisfied with their quality, there still are problems with the operation of the system.

- Specialists feel the lack of skills to work with the e-health system.

E-health and governance models - a scoping review

Line Linstad

L Linstad[1], *AG Ekeland*[1,2]
[1]University Hospital North Norway, Norwegian Centre for Ehealth Research, Tromsø, Norway
[2]UiT The Arctic University of Norway, Department of Clinical Medicine, Tromsø, Norway
Contact: line.linstad@ehealthresearch.no

Background:

Research has shown that national large-scale e-health projects are rarely defined as successful. **Methods:** We have conducted a search in the PubMed database on governance models.

Results:

Our search resulted in 220 hits, 11 papers included. We sorted these in four health systems Governance takes three different paths. 1) governance of e-health - how governments govern e-health programs through national and regional strategies, standards, incentives, legislation 2) governance through e-health - e-health as a strategic tool to obtain national health policy goals 3) governance in e-health - governance in medical networks initiated bottom-up and run by clinicians.

In the Single-Payer we find two papers. Both these describe governance of e-health. When the processes had been running for a period of time it shifted to governance through e-health. Two papers from New Zealand describe top-down governance model of e-health. Under the Multi-Payer health system we find a paper that describes the experiences of realizing a national telehealth network in Australia through a governance model in e-health. Under Unknown health system and national governance models, we include a paper that describes a governance model of e-health in Haiti. Two other papers describe the tension between non-profit and for-profit organizations on access to health data and domain names. The authors questions how governments shall realize governance models which captures these new aspects in healthcare. The second paper describes the challenges faced by the authorities' governance of the purchase and sale of health domains when public health institutions do not have an overview of this. The papers in this category may question if there is a need for a fourth governance model in e-health on the global level.

Conclusions:

The development of governance models are not static but part of processes and context dependent. Need for a fourth governance model on the global level.

Key messages:

- Research has shown that national large-scale e-health projects are rarely defined as successful.
- Currently scattered knowledge on how large-scale e-health projects that bring economic, clinical and societal benefits are governed.

How effective is AAL? Results from an RCT among older persons in Austria

Kerstin Loeffler

L Schmidt[1], *K Majcen*[2], *K Löffler*[3], *E Schuster*[4], *T Augustin*[1], *S Murg*[2], *C König*[1], *J Steiner*[4]
[1]Health, Joanneum Research, Graz, Austria
[2]Digital, Joanneum Research, Graz, Austria
[3]GGZ, Graz, Austria
[4]Sozialverein Deutschlandsberg, Deutschlandsberg, Austria
Contact: kerstin.loeffler@stadt.graz.at

Background:

Many older people wish to remain in their own environment for as long as possible; an aim shared by the wider community. Here the results of the RegionAAL study (Steiermark, Austria) are reported.

Methods:

An RCT was implemented to evaluate a programme of interventions (e.g. medication, drink and physical activity reminders, automatic light systems, watches to detect falls, video telephone with carers). Data was collected via quantitative questionnaires at baseline, 6 months and 1 year regarding quality of life and carers' burden.

Results:

111 persons and 104 carers took part in the intervention group; 110 participants and 100 carers in the control group. Participant characteristics were similar at baseline. Average age was 76 years. Around 1/3 were formal carers. A tendency for more persons in the control group to require assistance after one year could be observed. The subscales autonomy and participation of the WHOQOL-OLD showed some significant declines in the control group (no deterioration in the intervention group). No differences between study arms regarding general health, chronic conditions or hospital admissions were observed. Expected reduction in worry among carers could not be observed, although there was a tendency for some aspects of burden to be reduced. The interventions did not lead to a reduction in carers' workload; neither did the carers see any direct improvement of their situation.

Conclusions:

Some technologies such as cognitive games on the tablet, portable door bell and automatic light sensor were positively assessed. The participants in the intervention group scored better on autonomy and participation subscales than the control group; the intervention group also fared somewhat better regarding independence. The technologies had little influence on general health states or quality of life of participants or carers. Further good quality studies are needed before AAL technologies are considered as a public health initiative.

Key messages:

- AAL may reduce aspects of worry among carers and prevent age-related decline in autonomy, participation and independence among older persons but not have an effect on general health status or burden.
- AAL has only a very limited impact upon general health status or quality of life of older persons and the general burden experienced by carers.

Visualising Q - from the bootstrap to interactive graphics

Anthony Staines

A Staines[1], *S Gauttier*[2], *R Connolly*[1], *P Davis*[1], *J Connolly*[1], *D Weston*[3], *A Boilson*[1]

Introduction:

The MIDAS (Meaningful Integration of Data Analytics and Services) project is developing a big data platform to maximize the use of health & social care data. The goal is to link data sources to support senior managers & policy makers in delivering services. The project includes 4 case studies, in 4 countries. As part of the evaluation, we need to understand the perspectives of the users, developers, and senior managers involved, and to see how these change over time. We employ Q-methodology, an objective mixed method for the study of human perspectives, to do this. In this paper we describe the use of bootstrap methods, and visualizations to assist in the execution and interpretation of the first round of our Q study.

Methods:

A concourse of 36 items was developed from the literature, a logic model for the project, and a series of semi-structured interviews with project participants. Sixteen people (3 female, and 13 male) took part in the Q study, six developers, five managers, two health professionals, and 3 others. The 36 statements on the concourse were ranked online, by each participant, using the HTMLQ software, in order of their agreement with each statement. These are then subjected to a form of factor analysis, but by person, not by statement, using the qmethod package in R.

For each Q-sort 1,000 bootstrap replications were done, using sampling with replacement. A range of visualisations were prepared, using ggplot2.

Results:

Visualizations of bias and variability showed modest levels of both, suggesting that the Q-method model fitted well. Interactive visualizations of the factors, and respondents, were done. These showed distinct clusters of respondents, with divergent perspectives on the project. These assisted in making final decisions, both on the number of factors to report on, and the interpretation of those factors.

Further use of advance visualisations is recommended for future Q-studies.

Funded by the European commission under contract 727721

Key messages:

- Q methodology is useful across many areas of public health, and is a valuable way of studying individual perspectives.
- Modern statistical visualisation tools can enhance the interpretation of Q methodology studies.

Training on health communication and social media: European public health residents' perceptions

Francesca de Nard

F de Nard[1], *E De Vita*[2], *F Quattrone*[2], *R Thomas*[3,5], *L de la Torre*[4,6]
[1]Biomedical Sciences for Health, University of Milan, Milan, Italy
[2]Traslational Research, New Technologies in Medicine, University of Pisa, Pisa, Italy
[3]Public Health Sciences, University of Turin, Turin, Italy
[4]Servei de Medicina Preventiva i Epidemiologia, Hospital Clinic de Barcelona, Barcelona, Spain
[5]Euronet Leads, EuroNet MRPH, Paris, France
[6]Euronet Board, EuroNet MRPH, Paris, France
Contact: francesca.denard@unimi.it

Background:

Theoretical knowledge about health communication (HC) and expertise in planning, implementation and evaluation of HC interventions are essential tools for Public Health (PH) specialists. In the social media (SM) era, specific abilities and digital communication skills are gaining importance.

Objective:

Our aim is to describe European PH residents' perceptions regarding their training in the HC field, with a focus on SM. We piloted a survey using Google Forms during the European Network of Medical Residents in PH (EuroNet MRPH) meeting in Turin, April 2019. We then spread the survey to other PH residents across Europe in July 2019. The survey consists of 25 questions (Likert scales from 1 = strongly disagree to 5 = strongly agree, or multiple-choices) divided in 5 thematic sections (HC theory, public speaking, traditional media based HC, SM based HC, HC impact evaluation). Questions aim to map HC topics covered in residency educational programs, learning methods, and the perceived importance of HC skills.

Results:

The study included 114 residents from 10 countries (37% Italy, 23% Portugal, 10% UK, 9% Spain, 8% France, 13% other). Participants perceived they receive the best training in the areas of public speaking, impact assessment and HC theory (median 3, IQR 2-4). Conversely, for traditional and SM based HC, training was perceived as unsatisfactory (median 2, IQR 1-4 and 1-3 respectively) with self-education as main learning method (51%). Public speaking and traditional HC were identified as the most important HC skills for PH specialists (median 5, IQR 5-5), while less importance was attributed to SM based HC (median 3,5, IQR 3,25-5).

Conclusions:

Despite SM are playing a crucial role in public HC, specific training seems to be scarce in this sample. Although residents perceive SM based HC skills as important, they consider them less important than other HC skills. Further analysis is needed in order to explore the perceived relevance of SM in PH residents training.

Key messages:

- Training on health communication via social media is scarce among European public health residencies. Common training programs across European residencies in PH should address this educational need.
- European public health residents perceive social media based health communication skills as important, but not as important as traditional media based health communication skills.

A digitalized methodology to strengthen health equity: control, influence and participation

Moa Hallmyr

M Magnusson[1,2], *C Bertolino*[1], *M Hallmyr*[1]
[1]Public Healt Unit, Angered Hospital, SV Hospital Group, Region Västra Götaland, Sweden
[2]School of Health and Education, University of Skövde, Skövde, Sweden
Contact: moa.hallmyr.lewis@vgregion.se

Problem:

Angered Hospital is situated in the northeast of Gothenburg, Sweden, serving municipalities with high prevalence of ill health. Dedicated to increase health equity, the hospital has established a Public Health Unit (PHU) to support residents to healthier lives. PHU found that lack of transparency concerning strategies, reflections and results hindered knowledge-exchange between public health practitioners. Also, information from the execution of public health interventions and programs needed to be more accessible for policy-makers and researchers.

Description:

PHU developed a digitalized methodology for systematic steering. It draws on control, influence and participation, using Social Cognitive Theory to plan for strategies. The evaluation build on norm-critical reflections of structured reports. Themes include: How to improve efforts on the structural level? What measures do we plan for and conduct to enhance participation from residents? Quantitative goals were set.

Results:

222 activity reports were launched and discussed by team members, leading to professional development. Strategies to support self-efficacy were used throughout. The strategy ''reciprocal determinism'' was planned for more than used, due to giving floor to participants to raise their issues. Methods that draw on transparency, sound evidence and continous collaboration allow for residents to rethink their lifestyle and strive for change. Issues for future development included the importance og giving time for trust and shared values to emerge. Quantitive goals were reached.

Lessons:

Quality assurance of public health work enables formative and summative evaluation, increases potential to close the health gap, provides policy-makers with valuable knowledge and opens for research. Trust and shared values are vital at all levels. The methodology allows for organizations to develop their health literacy in order to include and give voice to people in underserved areas.

Key messages:

- Public health units aiming at health equity should use tailored evidence based methods, including norm-critical reflections.
- Digitalizing a methodological instrument increases accessability and transparency which enables common knowledge development.

Social network and grief: a text mining analysis

Elisabetta Corvo

E Corvo[1], *W De Caro*[2]
[1]School of Allied and Public Health Professions, Canterbury Christ Church, Canterbury, UK
[2]CNAI Italian Nurses Association, Milan, Italy
Contact: elisabetta.corvo@canterbury.ac.uk

Introduction:

Grief represents a multifaceted response to loss. Several dimension such as physical, cognitive, social, spiritual and philosophical are involved while an individual is experiencing loss. Often bereavement and grief are used interchangeably, however they are two very different concepts, bereavement refers to the state of loss while grief is the reaction to that loss. Each individual experiences loss differently, this is often connected to the culture of the individual in terms of culture per se or religion. Furthermore loss pertains not only to the individual who is directly involved and to its family but the entire environment of the person, in terms of community for instance. How individuals live and communicate death, loss and grief on online social network seems to have a role in coping and managing the loss itself.

Methods:

Text mining analysis was performed using web tools and Taltac 2.11. A text analysis of posts and discussion on open online social network was carried out in order to better detect which kind of coping activity was developed by participants. Specifically 149 losses post and more than 10.000 comments were analyzed.

Results:

Loss, bereavement and grief represent one of the most relevant topics on social network. Two main themes were identified. The first is focused on religion and spiritual support in faith, while the second on emotional support and affective-type closeness in which friends (virtual or not) support other individual having previously experienced the same losses. Analysis suggests that individuals are able to support peers in a wide range of way, furthermore virtual support is easier and more straight forward with respect to traditional and face to face relationship.

Conclusions:

This study display that individuals recognized a new way to be supported through social network. Individuals feel to be with close friends and at the same time to have the opportunity to live the loss by themselves without a face to face relationship.

Key messages:

- Social network 4 grief.
- Virtual friend give support.

Media Freedom is the Primary Culprit for Depressive Disorders: A Cross-National Analysis

Yuchun Lin

YC Lin[1], HT Yan[2]

[1]Chinese Medicine Department, China Medical University Hospital, Taichung City, Taiwan

[2]Department of Government, University of Essex, Colchester, UK

Contact: yclinjoyce@gmail.com

Background:

There has been much speculation about social environments causing an epidemic of depression. The objectives of this study are to examine how media freedom influences prevalence of depressive disorders. A direct effect of free media is great levels of information complexity causing poor mental health. Two indirect effects are that media freedom facilitates modernization, which is associated with competition-related stress, and government investment in social protection, which impedes the person's ability to manage stress.

Methods:

The study used a cross-sectional analysis on determinants of prevalence of depressive disorders in 2015 covering 98 democratic countries. Media freedom was measured as the degree to which a country allows the freedom of news and information of print media, television, and radio broadcasting (0-100: least to most free). Control variables were then added, including GDP per capita growth, population density, country latitude, and religious affiliations. Further, a mediation analysis was applied to test if there is a causal pathway that links the degrees of media freedom and the levels of economic development or/and social protection to prevalence of depression.

Results:

We found that an increase in the score of media freedom by 10 resulted in a 0.20 percentage point increase in prevalence of depressive disorders (%) (0.20, CI = 0.10-0.30). Our theoretical expectations were still confirmed when this study examined the relationship for each year between 2011 and 2014 (e.g. in 2014, 0.19, CI = 0.09-0.29), used an alternative index of media freedom from a practitioners' view (0.17, CI = 0.02-0.32), or measured each country's level of internet and digital media freedom (0.30, CI = 0.10-0.49). Further, a mediation test showed that 39.88% and 21.38% of the total effect was mediated through the economic and social pathway respectively.

Conclusions:

The findings suggest that great levels of media freedom matter in increasing prevalence of depression.

Key messages:

- Great levels of media freedom matter in increasing prevalence of depression.
- There are direct and two indirect effects of media freedom on prevalence of depression.

Parents and health professionals' opinions on information tools on mandatory childhood vaccines

Pierre Verger

CH Hennequin[1], CV Vergelys[1], LC Chauvet[1], SC Cortaredona[3,4], ED Dube[2], PV Verger[1,3,4]

[1]ORS PACA, Southeastern Health Regional Observatory, Marseilles, France

[2]Anthropology Department, Laval University, Quebec City, Canada

[3]Aix Marseille University, IRD, AP-HM, SSA, VITROME, Marseilles, France

[4]IHU-Méditerranée Infection, Marseilles, France

Contact: pierre.verger@inserm.fr

Background:

South-eastern France is marked by insufficient vaccination coverage for several vaccines and some mistrust of its population towards vaccination. In this context and given the application of new vaccination obligations for early childhood, we carried out a qualitative survey to study opinions of parents and health professionals (HPs) on information tools on vaccination (ITV).

Methods:

An inventory of French existing ITV was conducted to select a diverse set of 17 ITV for our qualitative evaluation. In 2018, we carried out 26 individual interviews with parents of young children (recruited in nurseries and kindergartens) and 5 focus groups with HPs (nurses, general practitioners, midwives and pediatricians; n = 33).

Results:

Most parents appreciated videos for their convenience: they used them to discover new/complex subjects in an entertaining way. Paper ITV remained essential mostly among parents with high socio-economic status (SES) or marked vaccine hesitancy, who also requested detailed information and scientific sources. Some parents of low SES considered ITV difficult to understand because of their length, quantity of information and scientific language. For HPs, giving their patients a paper ITV is a way to show the importance they attach to their patient's questions. HPs reported reluctance using videos during consultations. Some HPs stated their need for guidance on two aspects: 1) key discussion points to use when giving an ITV to parents and 2) most appropriate timing to give ITVs: prescription, injection. . .

Conclusions:

In the pool of tested ITV, articulation and formatting of arguments are not always optimal for HP and parents use. Tailored ITV should be available for the different needs of HP and parents, especially, for the latter, according to their SES and hesitancy profiles. ITV adapted to use during consultation are necessary.

Key messages:

- Information tools on vaccination (ITV) are not always optimal for HP and parents use.
- ITV should be tested and better adapted to the patient profile and consultation context.

The professional experience of a public health intern: How to promote health through a comic strip

Laetitia Leuci

L Leuci[1]
[1]Ireps, Cote-d'Or, Dijon, France
Contact: laetitia.leuci@gmail.com

Issue/problem:

Public health is a complex discipline often misunderstood by medical students. The way these future professionals get to grips with this subject may impact their career.

Description of the problem:

Starting in November 2018, a young public health intern, who also happens to be an illustrator, shares with us her medical journey through a comic broadcasted online. This innovative approach aims to demystify public health to medical students and could potentially raise their interest in the profession. The author started her residency training at the French Regional Authority of Health Promotion and Education (Instance Régionale d'Éducation et Promotion de la Santé - IREPS).

Results:

She recounts some of her professional anecdotes: an empowerment project for struggling young people, a survey on environmental health... The chapters of her comic are periodically shared on social media to professional members and public health interns in Dijon. The French organization of Public Health Interns (Collège de Liaison des Internes de Santé Publique de France - CLISP) has been contacted to publish the comic nationally. An English translation has been considered as well. A printed edition will be distributed to medical students of the region during an introductory course in public health.

Lessons:

This experiential comic strip enables the intern to conduct a self-analysis of her work. The short format of each chapter obliges the author to focus on some understandable key messages. The comic strip receives a warm welcome as well as by the professional members of IREPS, and the young and skilled co-interns who all appreciate this discipline being presented under a new light.

Key messages:

- The comics strip represents a great tool to transfer knowledge in public health as it is attractive and ludic.
- It is essential to provide a better understanding of public health.

5.S. Health at work, sickness absence and disability pension

Empowerment: a key to promote the health of people with disabilities

Séverine Lafitte

S Lafitte[1], *C Ferron*[1], *L Mussillier*[1], *S Poli*[1,2], *C L'Horset*[1,3], *M Masrouby*[1,3], *L Bidaux*[4], *F Alias*[1,5]
[1]FNES, Saint Denis, France
[2]Ireps Nouvelle-Aquitaine, Bordeaux, France
[3]Ireps Bourgogne-Franche-Comté, Dijon, France
[4]Institut Départemental de l'Enfance, de la Famille et du Handicap pour l'Insertion, Canteleu, France
[5]Ireps Occitanie, Toulouse, France
Contact: severine.lafitte@fnes.fr

In France, health public policies for people with disabilities are based on specific laws, recommendations and systems of reference. This population is under the responsibility of the medico-social sector, which governs specialized institutions and services. These services favor a medical approach to health focused on access to care. Their main missions are to take care of disabled people with kindness on a daily basis and to adapt the care to each person's special needs, whatever the disability. They create links with families, organize the services offered and the living environments, administer their staff and collaborate with health professionals. As they ensure safety and health at all levels, from every individual project to collective life, they have a real opportunity to act on a set of health determinants.

The Ottawa Charter for Health Promotion refers to the empowerment and participation of the population as fundamental principles; this is also true as far as people with disabilities are concerned. With the principal stakeholders on a national level, we wrote a handbook in order to support the implementation of these principles in medico-social institutions and services: 'Promoting health and well-being in the medico-social field in cooperation with people with disabilities'' and their families.

In this presentation, based on concrete examples, we will outline how the five intervention strategies of the Ottawa Charter can apply to people with disabilities, their families and their communities, especially inside specialized institutions and services. We will pay particular attention to the intervention methods and pedagogical tools which can be used to initiate or to improve the participation of disabled people in decisions, through the valuing of their experiential expertise, the development of their social skills, the strengthening of their health literacy, family-professional co-education, and cooperative strategies.

Key messages:

- Specialized institutions and services can promote the health of the people with disabilities they care for, by acting on the determinants of their health and by mobilizing participatory strategies.
- To strengthen disabled people's participation, using their experiential expertise, developing their social skills and health literacy, and mobilizing co-education, are the best strategies.

How often do partial disability pensioners end up on a full disability pension?

Anu Polvinen

A Polvinen[1], *M Laaksonen*[1]
[1]The Finnish Centre for Pensions, Helsinki, Finland
Contact: anu.polvinen@etk.fi

Background:

Extending working lives and deferring retirement have been important topics of discussion in recent years. Full disability pensioners seldom work, but most partial disability pensioners continuing working while receiving a pension. However, very little is known about how often partial disability pensioners end up on a full disability pension. The aims of this study were to investigate to what degree partial disability pensions become full disability pensions, and how age, gender, marital status, education, unemployment or a disability diagnosis are associated with that.

Methods:

The register data included 2,969 Finns who were aged 18-59 years and whose partial disability retirement started in 2010. The follow-up period ranged from 2010 to the end of 2015. Cox models were used to estimate hazard ratios for full disability retirement.

Results:

Approximately 40 per cent of the partial disability pensioners ended up on a full disability pension during the follow-up period. Partial disability pensioners who were older, had a lower educational level or a history of unemployment, or who suffered from mental disorders ended up on a full disability pension more often than others. The risk of full disability retirement was 1.5-fold among those with mental disorders compared to those with musculoskeletal diseases.

Conclusions:

Partial disability pensioners with a low education, a history of unemployment or who suffer from mental disorders experience a higher risk of ending up on a full disability pension. More focus should be paid to improving education, preventing mental health problems and unemployment in order to help the disabled work longer.

Key messages:

- Preventing partial disability pensioners from ending up on a full disability pension can extend their working lives.
- Partial disability pensioners with a low education, a history of unemployment or poor mental health more often stop working altogether. More focus should be paid to improving these issues.

Sickness absence and disability pension sequences before and after a bicycle crash; a Swedish study

Linnea Kjeldgård

L Kjeldgård[1], H Stigson[1,2,3], K Alexanderson[1], E Friberg[1]
[1]Division of Insurence Medicine, Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden
[2]Vehicle Safety Division, Department of Applied Mechanics, Chalmers University of Technology, Gothenburg, Sweden
[3]Folksam Research, Stockholm, Sweden
Contact: linnea.kjeldgard@ki.se

Background:

In recent years, bicycle injuries have increased, yet little is known about impact of such injures on sickness absence (SA) and disability pension (DP). The aim was to explore the long-term patterns of SA and DP among injured bicyclists.

Methods:

A longitudinal register-based study was conducted, including all individuals aged 18-59 years and living in Sweden, who in 2010 had incident in- or specialized out-patient healthcare for injuries sustained in a bicycle crash. Information about sociodemographics, the injury, SA, DP, and deaths were obtained from several nationwide registers. Weekly SA/DP data for four years: one year before and three years after the crash were used in sequence and cluster analyses. Multinomial logistic regression was used to estimate odds ratios (OR) and 95% confidence intervals (CI) for factors associated with each sequence cluster.

Results:

Among all 6465 individuals injured in a bicycle crash 2010, five clusters were identified: No SA or DP (60.2%), Immediate SA (17.7%), Episodic SA (15.3%), Part-time DP (1.6%), and Full-time DP (5.2%). Compared to the cluster No SA or DP, all other clusters had high ORs for female sex, older age, living in small cities/villages, and inpatient care. Immediate SA also had high ORs for cyclists who sustained a fracture (OR 5.53; CI 4.47-6.83), dislocation (3.26; 2.29-4.65), sprains and strains (2.29; 1.68-3.10), and internal injuries (4.39; 1.95-9.90). Episodic SA had high ORs for other traumatic brain injury than concussion (6.27; 2.23-17.64) and injuries located in the spine and back (3.52; 2.12-5.86), torso (1.78; 1.29-2.45), upper extremities (1.95; 1.54-2.46), and lower extremities (1.85; 1.43-2.41).

Conclusions:

Having SA in direct connection to the crash was associated with type of injury, in contrast to Episodic SA where the injured body region was of more importance, in particular other traumatic brain injuries and injuries to the spine and back.

Key messages:

- This nationwide study of new bicycle crashes found five clusters of sickness absence (SA) and disability pension (DP) sequences; No SA or DP, Immediate SA, Episodic SA, Part-time DP, and Full-time DP.
- The type of injury was more important for SA in direct connection to the crash, while the injured body region was of more importance for continued and repeated SA up to three years after the crash.

Sickness absence trajectories following labour market participation patterns in Catalonia, 2012-2014

Julio Cesar Hernando Rodriguez

JC Hernando-Rodriguez[1,2,3], L Serra-Saurina[1,2,3], FG Benavides[1,2,3], M Ubalde-Lopez[1,2,3]
[1]Experimental and Health Sciences, Universitat Pompeu Fabra, Center for Research in Occupational Health, Barcelona, Spain
[2]IMIM - Parc Salut Mar, Barcelona, Spain
[3]CIBER of Epidemiology and Public Health, Madrid, Spain
Contact: juliocesar.hernando01@estudiant.upf.edu

Background:

Working life is characterized by transitions between different employment status which could affect future health status. Previous studies on sickness absence (SA) have focused on risk factors in the workplace; however, there is scarce evidence regarding labour market participation (LMP) patterns. The aim of this study is to examine the association between prior LMP patterns and the course of SA.

Methods:

Cohort study based on a sample of 11,968 salaried workers affiliated with the Spanish Social Security system, living in Catalonia, who accumulated more than 15 days on SA at least in one quarter during 2012-2014, from three working life cohorts according to the working life stage in 2002: early (18-25 years), middle (26-35 years) and late (36-45 years). Sequence analysis was used to identify LMP patterns (2002-2011). Latent class growth analysis was applied to identify SA trajectories (2012-2014). Finally, crude and adjusted odds ratios (aOR) were estimated using multinomial logistic regression models.

Results:

Overall, four SA trajectories were identified: low stable (83%-88% of the workers), decreasing (5%-9%), increasing (5%-11%) and high stable (7%-16%) accumulated days on SA, for men and women. Similarly, seven LMP patterns were obtained: stable employment (63%-81%), increasing employment (5%-22%), delayed employment (7%-8%), decreasing employment (4%-10%), varying employment (13%-14%), steeply decreasing employment (9%), and steeply labour market exit (8%). No significant associations were observed among LMP patterns and SA trajectories, except for young men, where an increasing employment pattern was significantly associated with a lower risk to increase days on SA over time (aOR: 0.21 [95% CI: 0.04-0.96]).

Conclusions:

A prior 10 years of LMP pattern does not seem to show an effect on the course of SA. A closer working life to the SA course could be considered to assess this relationship.

Funding: Grants FIS PI17/00220 and PI14/00057

Key messages:

- A longitudinally approach is warranted to evaluate the relationship between working life and sickness absence.
- Extended prior working lives are not related to the course of future sickness absence.

Sick leave and disability pension before and after breast cancer diagnosis: a Swedish cohort study

Lingjing Chen

LC Chen[1], KA Alexanderson[1]
[1]Division of Insurance Medicine, Karolinska Institutet, Sweden, Sweden
Contact: lingjing.chen@ki.se

Background:

Most working-aged women are, after diagnosed with breast cancer (BC), on some sickness absence and/or disability pension (SADP). We aimed to explore possible trajectories of their previous and subsequent SADP days and risk factors for consistently high levels of future SADP.

Methods:

In a longitudinal cohort study of all 3536 women in Sweden aged 19-64 with a first BC diagnosis in 2010, we calculated their annual SADP net days from two years before to three years after BC diagnosis date. A group-based trajectory model was applied to depict SADP patterns. Logistic regressions were used to calculate odds ratios (OR) with 95% confidence intervals (CI) for having >90 or > 180 SADP days/year in the three postdiagnostic years.

Results:

Three trajectories of SADP days/month over the five years were identified: ''high'' (30% of all)'', ''increase only around diagnosis'' (61%), and 'constant very high' (9%). Across the study period, the risk factors associated with constantly high levels of SADP days (>90 or > 180 days/year) were similar. Particularly, factors significantly associated with having annual SADP >90 days during all the three postdiagnostic years were: stage II cancer (OR = 4.59; 95% CI 2.98-7.07), stage III+IV (OR = 26.57; 13.52-52.22), prediagnosis SA 1-30 days (OR = 2.73; 1.30-5.70), prediagnosis SA > 90 days (OR = 24.52; 12.25-49.08), and prediagnosis DP (OR = 659.97; 292.52->999.99).

Conclusions:

When diagnosed with BC, SADP increased significantly postdiagnosis, however, decreased with time and the absolute majority had no SADP the third year after BC diagnosis. Advanced cancer stage and previous high SADP were the highest risk factors for later SADP.

Key messages:

- Most breast cancer survivors' work capacity (sickness absence (SA) and disability pension (DP) is only affected shortly post-diagnosis. Prior SADP and high cancer stage were strongest risk factors.
- Register-based information on breast cancer patients and their sickness absence and disability pension before and after diagnosis are useful to identify different types of return-to-work patterns.

Effects of a work-stress intervention in Swedish primary care versus treatment as usual: RCT-study

Christine Sandheimer

C Sandheimer[1], T Hedenrud[1], G Hensing[1], K Holmgren[2]
[1]Department of Community Medicine and Public Health, University of Gothenburg, Gothenburg, Sweden
[2]Institute of Neuroscience and Physiology, University of Gothenburg, Gothenburg, Sweden
Contact: christine.sandheimer@gu.se

Background:

Work stress is an increasing burden in society. To identify early symptoms of work stress in primary health care (PHC) could result in earlier and better adjusted care. A work stress questionnaire (WSQ) was developed in PHC for this task. We aimed to evaluate if the use of WSQ, in combination with physician's feedback, results in differences in health care visits and treatment compared to treatment as usual (TAU) in patients reporting high stress. Our hypothesis was that patients receiving the intervention would generate more visits to rehabilitation providers during follow-up compared to TAU.

Methods:

A two-armed RCT was conducted at seven primary health care centres (PHCC) in Region Västra Götaland, Sweden. One group received the WSQ-intervention and the controls received TAU. Employed not sick-listed persons aged 18-64 that sought care for mental and physical health complaints at the PHCCs participated. Register data on health care visits and treatments 12 months prior inclusion and 12 months after was obtained and analysed with Fisher's exact test together with questionnaire data (WSQ and background features).

Results:

A total of 271 participants were included in the study, 132 intervention and 139 controls. The proportion that visited psychologists/psychotherapists was higher among the intervention group with high stress (19.5%, n = 87) during follow-up compared to corresponding controls (7.2%, n = 97) (p = 0.048). Collaborative care measures were more common among the stressed intervention participants (23%) post-inclusion compared to the stressed controls (11.3%) (p = 0.048).

Conclusions:

Significant differences were found between the WSQ intervention group and the controls reporting high stress in visits to psychologists and in amount of received collaborative care. This confirms our hypothesis that the WSQ can help physicians to identify work stress and give suitable rehabilitative measures at an earlier stage in the care process compared to TAU.

Key messages:

- The use of WSQ with physicians' feedback generated more visits to psychologists and more received collaborative care compared to treatment as usual.
- Findings of the study indicate that the WSQ can assist in identifying work stress in primary care and accommodate rehabilitative measures compared to treatment as usual.

Work disability before and after incident myocardial infarction and subsequent common mental disorder

Syed Rahman

K Bokenberger[1], S Rahman[1], M Wang[1], M Vaez[1], TE Dorner[1,2], M Helgesson[1], T Ivert[1,3,4], E Mittendorfer-Rutz[1]
[1]Insurance Medicine, Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden
[2]Medizinische Universitat Wien, Institute of Social Medicine, Centre for Public Health, Viena, Austria
[3]Department of Cardiothoracic Surgery and Anesthesiology, Karolinska Institutet, Stockholm, Sweden
[4]Department of Molecular Medicine and Surgery, Karolinska Institutet, Stockholm, Sweden
Contact: syed.rahman@ki.se

Background:

This study investigated the extent to which work-disability patterns including sickness absence and disability pension (SA/DP) before and after acute myocardial infarction (AMI) were associated with subsequent common mental disorders (CMDs) such as depression and anxiety in AMI patients without previous CMD.

Methods:

A cohort of 11,493 patients aged 26-64 years without previous CMD with incident AMI during 2008-2010 were followed up for CMD measured as antidepressant prescription through 2013. Four SA/DP trajectory groups during the 3 years pre-AMI and 1 year post-AMI were identified. Hazard ratios (HR) and 95% confidence intervals (CI) were estimated in Cox models.

Results:

Higher pre-AMI SA/DP levels (>1-12 months/year), compared to the majority of patients (78%) following low increasing annual levels (increasing up to 1 month/year) of pre-AMI SA/DP, were associated with a 40-60% increased CMD rate. Regarding post-AMI findings, constant high (~25-30 days/month) and steeply decreasing SA/DP levels within the first 3 months were associated with a 76% and 35% higher CMD rate, respectively, compared to constant low (<1 days/month) levels. Conversely, a gradually decreasing pattern of post-AMI SA/DP over a 12-month period suggested protective influences for CMD (HR = 0.80), even after adjusting for sociodemographic and medical factors.

Conclusions:

This is the first study to demonstrate that pre- and post-AMI work disability patterns are associated with subsequent CMD risk in AMI patients. Work disability patterns should be considered in clinical practice as an indicator of AMI prognosis in terms of CMD risk.

Key messages:

- Increasing and high persistent levels of pre-AMI work disability are associated with higher risk of subsequent

CMD, while gradually decreasing post-AMI work disability has a favourable CMD prognosis.
- Pre- and post-AMI patterns of work disability (sickness absence and disability pension) can be a useful marker in terms of CMD prognosis.

Childhood adversities and chronic pain among midlife employees
Aino Salonsalmi

A Salonsalmi[1], *T Lallukka*[2,1], *E Lahelma*[1], *O Pietiläinen*[1], *O Rahkonen*[1]
[1]Department of Public Health, University of Helsinki, Helsinki, Finland

Contact: aino.salonsalmi@helsinki.fi

Introduction:

Chronic pain is common among employees. Childhood adversities are known determinants of adult health but their association with chronic pain in adulthood is largely unknown. We aimed to examine the associations between childhood adversities and chronic pain among midlife employees.

Methods:

Data on seven childhood adversities and chronic pain (pain having lasted at least 3 months) were derived from the baseline survey of the Helsinki Health Study collected in 2000 to 2002 among 40 to 60-year-old employees of the City of Helsinki in Finland. The study included 8140 employees of whom 80% were women. The analyses were made by logistic regression and the results are presented as odds ratios (OR) and their 95% confidence intervals (CI). Age, gender, father's education, own education, marital status, working conditions, sleep problems and common mental disorders were included as covariates.

Results:

Economic difficulties in the childhood family (OR 1.60, 95% CI 1.41-1.81), childhood illness (1.74, 1.45-2.08), parental divorce (1.26, 1.07-1.48), parental alcohol problems (1.34, 1.18-1.52) and bullying in school or among peers (1.59, 1.37-1.89) were associated with an increased odds of chronic pain in midlife. Adjusting for father's education, own education and marital status did not contribute to the associations. Working conditions, sleep problems and common mental disorders slightly attenuated the associations between childhood adversities and chronic pain.

Conclusions:

Childhood adversities associate to chronic pain in midlife. The results suggest that promoting well-being among children might lead to less pain decades after childhood.

Key messages:
- Childhood adversities are associated with chronic pain in adulthood.
- Considering well-being among children might lead to less pain decades after childhood.

Job demands & control among employees in Sweden aged 55-64 and labour market status 11 years later
Kristin Farrants

K Farrants[1], *K Alexanderson*[1]
[1]Division of Insurance Medicine, Department of Clinical Neuro, Karolinska Institutet, Stockholm, Sweden
Contact: kristin.farrants@ki.se

Background:

As discussions about extending working lives are ongoing, more knowledge is warranted on how psychosocial working conditions are associated with labour market status in older age.

Aim:

Among employees aged 55-64 years, explore associations between job demands/control with their labour market status 11 years later, using a job exposure matrix (JEM).

Methods:

A population-based prospective cohort study using nationwide register data. All 616,818 individuals in Sweden who in 2001 were in paid work and aged 55-64, were categorized using JEM into 9 groups, based on tertiles. They were followed up in 2012 regarding their labour market status (main income from: paid work, old-age pension, marginalised (no income/social assistance), sickness absence >183 net days, emigrated, dead) using multinomial logistic regression for odds ratios (OR) and 95% confidence intervals (CI), controlling for labour market status and sociodemographics in 2001. Analyses were stratified by sex.

Results:

The majority (women: 84.9%, men: 80.3%) had main income from old-age pension at the 11-year follow-up; 4.7% from paid work (women: 3.9%, men: 5.6%). Those initially in jobs with high demands were less likely to be marginalised at follow-up (OR women high demands/medium control 0.51, CI 0.38-0.68, high demands/high control 0.68, CI 0.50-0.92; OR men high demands/medium control 0.55, CI 0.31-0.96, high demands/high control 0.47, CI 0.30-0.73). Those in occupations with low demands were less likely to be in paid work (OR women low demands/low control 0.56, CI 0.51-0.62, low demands/medium control 0.63, CI 0.58-0.69; OR men low demands/low control 0.56, CI 0.51-0.63, low demands/medium control 0.63, CI 0.58-0.69).

Conclusions:

High job demands with high job control among people aged 55-64 in 2001 were associated with higher rate and OR of having main income from paid work in 2012, and high job demands regardless of level of job control were associated with less marginalisation.

Key messages:
- Levels of job demands when aged 55-64 were associated with labour market status 11 years later for women and men, while levels of job control were less so.
- High job demands were associated with a higher likelihood of being in paid work and lower likelihood of being marginalised at the end of follow-up.

Health inequality and self-employment in South Korea
HyeJin Kim

HyeJin Kim[1], *Jin-Young Min*[2], *Kyoung-Bok Min*[1]
[1]Department of Preventive Medicine, College of Medicine, Seoul National University, Seoul, South Korea
[2]Institute of Health and Environment, Seoul National University, Seoul, South Korea
Contact: okimhj@snu.ac.kr

Background:

Self-employed persons work for themselves as owners of a business rather than for an employer. Although self-employed persons have autonomy and flexibility, they are vulnerable to workplace health and safety hazards. However, there has been little interest in the health of self-employed persons, especially in small business owners. This study investigated the health status of small self-employed business owners compared to standard workers.

Methods:

The third Korean Working Conditions Survey for a total of 32,630 workers aged 20-59 were analyzed. A small business was defined as self-employment with 0-4 workers. Standard employment included full-time employment with a permanent or one-year contract. Health outcomes included the presence of depressive symptom and 8 types of physical health; hearing problems, skin problems, backache, muscular pains (upper limbs), muscular pains (lower limbs), headaches/eye strain, injuries, and overall fatigue.

Results:

Among 32,630 workers, 10,652 (32.64%) were small business self-employed. Compared with standard employed workers, small business self-employed had a 1.2-fold [adjusted OR (Odds Ratio) =1.20, 95%CI (Confidence Interval) 1.09-1.32] increased likelihood for depression after adjustment for potential covariates. Small business self-employed was at higher risk of work-related physical health problems: backache (OR = 1.16, 95%CI 1.06-1.26), muscular pains in upper limbs (OR = 1.19, 95%CI 1.12-1.27), and muscular pains in lower limbs (OR = 1.14, 95%CI 1.07-1.22).

Conclusions:

Our study found health inequality of small business self-employed, showing higher odds for mental and physical health problems in small business self-employed than in standardly employed workers.

Key messages:

- The current study showed vulnerability of self-employed in small business to health problems.
- Our study would be helpful to build up better working environment for small business owners and improve occupational health inequalities in South Korea.

Age-group differences in associations of working hour characteristics and short sickness absences

Annina Ropponen

A Ropponen[1], A Koskinen[1], S Puttonen[1], M Härmä[1]
[1]Finnish Institute of Occupational Health, Helsinki, Finland
Contact: annina.ropponen@ttl.fi

Background:

Working-hour characteristics are linked to disturbed sleep, but little is known about their association with short sickness absences (SA). We investigated the association between working hour characteristics in shift work and the incidence of short (1-3 days) SA in three age groups.

Methods:

The data was from the hospitals' electronic working time records. The final sample was restricted to the first incidence of short SA (1-3 days) from 2008 to 2015 and to shift working employees (n = 12156, 89% women). Age groups were < 35 (n = 5652), 35-49 (n = 3592) and ≤ 50 years (n = 2545). Work shifts (morning, day, evening, and night), quick returns (< 11 hours between two work shifts), length of work shift and weekly working time were calculated for case-crossover study design to compare the working hour characteristics of the 28 days preceding SA (exposure window) and those of the 28 days before the exposure window (control window). Conditional logistic regression models were run for odds ratios (OR) with 95% Confidence Intervals (95%CI).

Results:

Working hour characteristics, especially length of working hours, played the clearest role among those < 35 years of age. In this age group, exposure to > 25% of > 40 weekly working hours associated with an increased likelihood of short SA (OR 1.30, 95%CI 1.17-1.44), whereas weekly working hours had OR 1.02 (95%CI 1.02-1.03). Having only a few (≤ 4) quick returns decreased the likelihood of SA (ORs 0.31-0.54), whereas having ≥25 quick returns increased it (OR 2.75, 95%CI 2.44-3.11). The results showed mostly similar trends among those of 35-49 years of age whereas among older workers (≤ 50 years) only an association for quick returns was observed.

Conclusions:

Long working hours increase the risk of short SA among those ≤ 49 years of age and several quick returns among all age groups. These working-hour characteristics should be avoided to minimize SA and increased costs for the employer, but also to maintain public health.

Key messages:

- Unhealthy working-hour characteristics should be paid special attention in shift scheduling to avoid sickness absence.
- Good shift scheduling could assist in maintaining work-ability and therefore public health.

Gender and psychological distress: contribution of work-family balance

Satu Viertiö

S Viertiö[1,4], O Kiviruusu[1,4], M Piirtola[2], J Kaprio[2,3], T Korhonen[2], M Marttunen[1,4], J Suvisaari[1]
[1]Mental Health Unit, National Institute for Health and Welfare, Helsinki, Finland
[2]Institute for Molecular Medicine Finland, Helsinki, Finland
[3]Department of Public Health, University of Helsinki, Helsinki, Finland
[4]Psychiatry, University of Helsinki and Helsinki University Hospital, Helsinki, Finland
Contact: satu.viertio@thl.fi

Background:

Women suffer from psychological distress more often than men. Our aim was to investigate the potential contribution of work-family balance to this gender difference.

Methods:

Questionnaire data from the nationally representative 2013 Finnish Regional Health and Well-being Study (target population all adults aged 20 years or over, n = 88 377, response rate 53%), was restricted in the current analysis to those who were working and who had minor children (n = 26 442). Psychological distress was assessed using the Mental Health Index (MHI-5, cut off value< = 52). Participants answered six questions on balancing work and family demands (yes/no). We used logistic regression adjusted for age, education and marital status.

Results:

Women reported more distress than men (12.4% and 10.2% respectively, p = 0.000). We found statistically significant interactions between gender and two work-family demands (both p = 0.010): "I sometimes neglect my family when I am wholly absorbed in my work" was associated with distress in women (OR = 1.29, 95%CI 1.11-1.49), but not in men (OR = 0.95, 95%CI 0.79-1.14). "I feel inadequacy as a parent" had stronger association with distress in men (OR = 3.07, 95%CI 2.56-3.69) than in women (OR = 2.31, 95%CI 2.00-2.65). Both men and women had less psychological distress if they reported stopping thinking about their work at home or having more energy to be with the children when they also went to work. Correspondingly, they had more psychological distress if they felt they were neglecting home issues because of work or found hard to concentrate on work because of home issues. Common-law marriage was associated with psychological distress in women (OR = 1.43, 95%CI 1.22-1.68), but not in men (OR = 1.11, 95%CI 0.91-1.36).

Conclusions:

Women felt distress about neglecting family due to being absorbed in their work while men did not. Feelings of inadequacy as a parent were associated with distress more in men.

Key messages:

- Both women and men struggle to coordinate work and family, but expectations how job is divided may differ by gender.
- Actions to improve coordination between working life and family life are needed, both within families and by political decisions.

6.R. Mother and child health

Preterm delivery is associated with long-term risk of maternal renal disease

Peter Barrett

P Barrett[1,2], FP McCarthy[2], M Evans[3], M Kublickas[4], IJ Perry[1], P Stenvinkel[3], K Kublickiene[3], AS Khashan[1,2]
[1]School of Public Health, University College Cork, Cork, Ireland
[2]INFANT, University College Cork, Cork, Ireland
[3]CLINTEC, Karolinska Institutet, Stockholm, Sweden
[4]Department of Obstetrics, Karolinska Institutet, Stockholm, Sweden
Contact: peterbarrett1@hotmail.com

Background:

Preterm delivery is an independent risk factor for maternal cardiovascular disease. Little is known about the association between preterm delivery and maternal renal function, and whether any association is independent of preeclampsia or intra-uterine growth restriction. This study aimed to examine the association between gestational age and long-term maternal chronic kidney disease (CKD) and end-stage kidney disease (ESKD).

Methods:

Using data from the Swedish Medical Birth Register, singleton live births from 1973-2012 were identified and linked to data from the Swedish Renal Register and National Patient Register (up to 2013). Women with pre-pregnancy CKD/ESKD, cardiovascular disease, diabetes, hypertension, systemic lupus erythematosus were excluded. Gestational age at delivery was the main exposure, treated as a time-dependent variable. Primary outcomes were maternal CKD or ESKD. Cox regression was used, adjusting for maternal age, year of delivery, country of origin, education, parity, interpregnancy interval, smoking, BMI, gestational diabetes. Models were stratified by exposure to preeclampsia or small for gestational age (SGA).

Results:

There were 3,847,694 pregnancies among 1,990,273 unique women. Nine percent of women ($n = 172,915$) had at least one preterm delivery (<37 weeks). Exposure to preterm delivery was associated with higher risk of CKD (aHR 1.48, 95%CI 1.41-1.54) and ESKD (aHR 2.52, 95%CI 2.17-2.92). Earlier gestational age at delivery was associated with increasing risk of CKD and ESKD. Women with spontaneous preterm delivery were at higher risk of CKD (vs. normal term, aHR 1.33, 95% CI 1.26-1.40) and ESKD (aHR 2.02, 95%CI 1.69-2.40) independently of preeclampsia/SGA. Associations persisted after excluding women who developed postpartum cardiovascular disease, hypertension or diabetes.

Conclusions:

Women who gave birth at earlier gestation were at higher risk of later CKD and ESKD. This association persisted independently of preeclampsia and SGA.

Key messages:

- Preterm delivery is an independent predictor of long-term maternal renal disease.
- Obstetric history should be considered as part of overall risk stratification for chronic kidney disease in women.

Global trends in incidence and mortality of neonatal encephalopathy due to birth asphyxia and trauma

Kathryn Lau

K Lau[1]
[1]Department of Global Health, University of Washington, Seattle, USA
Contact: klau314@uw.edu

Background:

Neonatal encephalopathy due to birth asphyxia and trauma is a leading cause of premature death and long-term disability as estimated by the Global Burden of Disease (GBD) 2017 study. To evaluate comparative improvements in prevention and survival, this analysis evaluated GBD 2017 mortality to incidence (MI) ratios as a proxy for case fatality over time, location, and socio-demographic status.

Methods:

We derived estimates of cause-specific mortality and incidence at birth from GBD 2017, calculating MI ratios of neonatal encephalopathy in children <1 year. We analyzed temporal, geographic, and socio-demographic trends in incidence, mortality, and MI ratio.

Results:

Neonatal encephalopathy incidence shows little change over time, with global incidence in children under one essentially the same in 2017 (1,996 cases per 100,000 (1,334-2,912)) and 1990 (1,996 cases per 100,000 (1,331-2,926)). Regions show the same trend, though a large difference exists between the highest and lowest regional incidence, with incidence in Central Sub-Saharan Africa over 20 times higher than in Australasia. Over the same period, MI ratios for neonatal encephalopathy have decreased across all regions. Model input data represented 52 countries for prevalence and 145 countries for mortality, with notable data sparsity in Africa and Eastern Europe.

Conclusions:

Case fatality of neonatal encephalopathy, as approximated by MI ratio, has declined worldwide over the past three decades, but incidence has shown little change. This suggests treatment of neonatal encephalopathy has improved, but more research is needed on risk factors in order to increase prevention. Continued work is also needed to reduce disparities in incidence and mortality between countries with different levels of SDI. Improving data coverage in lower SDI regions will be critical to accurately monitor progress toward reducing inequity.

Key messages:

- Neonatal encephalopathy is a leading cause of premature death and disability. Incidence of neonatal encephalopathy has changed little since 1990, indicating more work is needed on prevention.
- Case fatality of neonatal encephalopathy can be approximated by the mortality to incidence ratio, and has declined worldwide over the past three decades, suggesting improvements in treatment.

Breastfeeding and Birth mode: comparative analysis between elective and in-labor caesarean section

Margherita Napolitani

M Napolitani[1]*, C Lorenzini*[1]*, L Kundisova*[1]*, F Crescenzo*[2]*, L Alaimo*[2]*, N Nante*[1,3]
[1]Post Graduate School of Publich Health, Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[2]Degree Course in Obstetrics, University of Siena, Siena, Italy
[3]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
Contact: napolitani1005@hotmail.it

Introduction:

Evidence in literature suggests that the outcomes of children born by in-labor non-emergency caesarean section (CS) are better if compared to those born by programmed CS. The aim of this work was to evaluate impact of type of CS on neonatal outcomes and breastfeeding.

Materials and methods:

The cross-sectional study was performed in the Siena province (hospital of Siena and Poggibonsi) during the period January-December 2015. All females that gave birth by CS were included, except those that had emergency CS from severe medical indication (pre-eclampsia/eclampsia, fetal distress, intrauterine growth retardation, etc) or due to multiple pregnancy.

The sample was divided in two groups (programmed CS/CS in the presence of labor). The outcome variables were: necessity of hospitalization in neonatal intensive therapy unit (NITU) or resuscitation; weight loss after birth (%), hours passed between birth and first attack to the breast, type of breastfeeding at discharge (exclusive/mixed). The statistical analysis was performed with Stata 12.

Results:

In total 446 females were included (53.6% programmed CS). Any association between the type of CS and admission to NITU or resuscitation was observed.

Among the newborns born by CS in the presence of labor, there was a greater proportion of babies who attached to the breast immediately after birth (82% vs. 71%; $p < 0.05$) and also those exclusively breastfed at the moment of discharge (71% vs. 60%; $p < 0.05$).

The weight loss was lower in babies born by CS in the presence of labor ($8\% \pm 1.8$; 95% CI 7.7%-8.2% vs. $8.53\% \pm 1.7\%$; 95% CI: 8.3%-8.8%; $p < 0.05$).

Conclusions:

Our study confirmed the negative impact of the CS in the absence of labor on the breastfeeding initiation, probably due to incomplete activation of neuroendocrine mechanisms (release of oxytocin; etc). The CS in the presence of labor is more stressful from the organizational point of view, but it helps promotion of health through the facilitation of breastfeeding.

Key messages:

- In-labor non-emergency caesarean section is more physiological and helps to initiate and maintain breastfeeding.
- The CS in the presence of labor is more stressful from the organizational point of view, but it helps promotion of health through the facilitation of breastfeeding.

Maternal obesity and severe preeclampsia among immigrant women: a mediation analysis

Elie Azria

[10]Maternity Unit, Notre Dame de Bon Secours -Paris Saint Joseph Hospital, University Hospital Department (DHU) Risks in Pregnancy, Paris Descartes University, Paris, France
Contact: eazria@hpsj.fr

Background:

Severe preeclampsia is known to be associated with both maternal place of birth and obesity. However, the role of prepregnancy obesity has not been well elucidated on the causal pathway between maternal origin and severe preeclampsia. We aimed to test for and quantify a mediation effect of obesity in this association.

Methods:

A secondary analysis of the PreCARE prospective French cohort of pregnant women (n = 9,579). Adjusted path analysis logistic regression models tested for a mediation effect of obesity in the association between maternal place of birth and severe preeclampsia. Adjusted odds ratios and 95% confidence intervals for the total exposure-outcome association and for the direct and indirect/obesity-mediated components were calculated in addition to an estimate of the indirect/obesity-mediated effect.

Results:

95 (0.99%) women developed severe preeclampsia: 47.6% were non-European immigrants, 16.3% were born in Sub-Saharan Africa, and 12.6% were obese. Obesity was both associated with Sub-Saharan African place of birth and severe preeclampsia. Women from Sub-Saharan Africa had an increased risk of severe preeclampsia compared to European-born mothers (aOR 2.53, 95% CI 1.39-4.58). The obesity-mediated effect of the association was 18% (aOR 1.18, 95%CI 1.03-1.35).

Conclusions: Sub-Saharan African immigrant women have a two-fold higher risk of developing severe preeclampsia as compared to European-born women, one-fifth of which is mediated by prepregnancy obesity. Our results provide estimates of the benefit of decreasing obesity among at-risk women.

Key messages:

- Obesity, a modifiable risk factor, is a target for interventions to prevent severe preeclampsia among immigrant women from Sub-Saharan Africa.
- Future investigations should focus on better elucidating the role of other modifiable mediators such as interaction with the health care system and quality of prenatal care.

Combined effect of adverse childhood experiences and young age on self-harm ideation after birth

Satomi Doi

S Doi[1], T Fujiwara[1]
[1]Department of Global Health Promotion, Tokyo Medical and Dental University, Bunkyo-ku, Japan
Contact: doi.hlth@tmd.ac.jp

Background:

Suicide among postpartum women is a new and emerging issue in developed countries. However, little is known about the combined effect of risk factors on self-harm ideation, although various risk factors have been found. The aim of this study is to examine the combined effect of maternal adverse childhood experiences and maternal age on self-harm ideation among postpartum women.

Methods:

The study comprised a cross-sectional study of 8,074 mothers participating in a 3-month health checkup between September 2013 and August 2014 in City A, Prefecture A, Japan. Main outcome was self-harm ideation assessed using the Edinburgh Postnatal Depression Scale (EPDS), item 10. Possible risk factors were maternal adverse childhood experiences (ACEs), maternal characteristics, relationship with husband/partner (e.g., feelings when pregnancy was confirmed), household characteristics, child characteristics (e.g., age, sex, birth weight), and postpartum characteristics, and postpartum depression status other than self-harm ideation.

Results:

Postpartum women with 3 or more ACEs and younger age (<25 years old) were 10.3 times more likely than those with no ACEs and older age to have self-harm ideation (95%CI = 5.3-20.2). This combined effect was also found in first-time mothers (OR = 7.6, 95%CI = 3.2-17.9).

Conclusions:

Postpartum women with 3 or more ACEs and who were younger than 25 years old were at a high risk for self-harm ideation. Providing prevention strategies aimed at mothers with multiple risk factors, especially younger age and ACEs, is warranted.

Key messages:

- Mothers with 3 or more ACEs and younger age had a high self-harm ideation risk.
- Providing prevention strategies for mothers with multiple risk factors is warranted.

The impact of psychosocial factors on breastfeeding duration in the BaBi cohort study, Germany

Celine Miani

A Grosser[1], I-M Doyle[2], A Löffler[3], J Breckenkamp[1], J Spallek[3], O Razum[1], C Miani[1]
[1]School of Public Health, Bielefeld University, Bielefeld, Germany
[2]Institute for General Practice, Hannover Medical School, Hannover, Germany
[3]Department of Public Health, Brandenburg University of Technology, Senftenberg, Germany
Contact: celine.miani@uni-bielefeld.de

Background:

Breastfeeding is considered beneficial for both mother and child. In Germany, national guidelines recommend fully breastfeeding for at least 4 months, a goal reached by only 34% of mothers in 2012. The WHO's recommendation of exclusively breastfeeding for six months was met by 19% only. Hardly modifiable factors such as socio-economic status and migration background have been associated with duration of breastfeeding but little is known about the impact of psychosocial factors such as personality traits and social support. We hypothesise that there are differences in the psychosocial profiles of mothers regarding the duration of breastfeeding.

Methods:

We analyse baseline and follow-up data of the Bielefeld BaBi birth cohort (2013-16). They include detailed migration and socio-economic backgrounds, as well as three measures of psychological characteristics: the optimism scale, the Big Five inventory and the locus of control scales. We perform bivariate and multivariate analyses in order to identify psychosocial determinants of fully breastfeeding for four and six months.

Results:

Out of 780 BaBi study participants, 548 fully breastfed for four months (70.3%), of which 279 continued until at least six months (35.8%). Logistic regression analyses show that fully breastfeeding for at least four or six months is independently associated with the intention to breastfeed and the attendance of antenatal class during this or previous pregnancies. Personality characteristics, social status and migration background show however no significant association with breastfeeding duration.

Conclusions:

Our study results support the promotion of individuals' breastfeeding intention and attendance to antenatal classes to increase breastfeeding duration. Since differences in breastfeeding practices have the potential to create inequalities in maternal and child health, more efforts are needed to intensify research on modifiable factors influencing breastfeeding duration.

Key messages:

- Neither psychosocial factors nor socioeconomic status were associated with breastfeeding duration.
- Two modifiable factors, breastfeeding intention and attending antenatal classes, were the main predictors of breastfeeding duration.

Postpartum women's experience of abuse in childhood, postnatal depression, and thoughts of self-harm

Sung-Hyun Cho

SH Cho[1], YH Khang[2], KJ June[3], JY Lee[4], HJ Cho[5], YM Kim[6]
[1]College of Nursing, Seoul National University, Seoul, South Korea
[2]College of Medicine, Seoul National University, Seoul, South Korea
[3]Department of Nursing, Soonchunhyang University, Cheonan, South Korea
[4]College of Nursing, Kangwon National University, Chuncheon, South Korea
[5]College of Medicine, University of Ulsan, Asan Medical Center, Seoul, South Korea
[6]College of Medicine, Dong-A University, Busan, South Korea
Contact: sunghcho@snu.ac.kr

Background:

Postnatal depression threatens the health of both mothers and babies. To improve maternal and child health in Seoul, South Korea, a nurse home visitation program for pregnant women and new mothers and babies has been implemented since 2013.

Methods:

Cross-sectional data collected from 9,124 mothers while they were visiting a public health center for prenatal services or a nurse was visiting their home within 6 weeks after birth between 2014 and 2018 were analyzed. Mothers were asked whether they had experienced physical, emotional, or sexual abuse in their childhood. Postnatal depression and thoughts of self-harm were measured using the Edinburgh Postnatal Depression Scale (EPDS). Postnatal depression was defined as a total EPDS score of 13 or higher; thoughts of self-harm were defined as a response of ''yes, quite often,'' ''sometimes,'' or ''hardly ever'' to the corresponding item, excluding the response of ''never".

Results:

Overall, 3.2% of mothers had experienced child abuse; 8.1% experienced postnatal depression and 5.4% reported thoughts of self-harm. Postnatal depression was more common in mothers who had experienced child abuse than among those who had not (24.2% vs. 7.6%). A similar pattern was found for thoughts of self-harm (21.1% vs. 4.9%, respectively). When controlling for mothers' age, economic status, history of receiving treatment for mental health problems, and other factors, having experienced child abuse was associated with a 2.73-fold increase in the odds of postnatal depression (odds ratio, 2.02-3.70) and a 3.58-fold increase in the odds of thoughts of self-harm (odds ratio, 2.58-4.96).

Conclusions:

Mothers should be screened for having experienced child abuse when providing public health perinatal care to improve mothers' mental health and parenting practices and to promote their children's growth and development.

Key messages:

- Child abuse may have a lifelong negative effect on victims, and the effect extends to the next generation's health and development.
- Public health policy and interventions to prevent child abuse are needed to tackle health inequality beginning in early childhood.

Prenatal care: missed opportunity for HBV prevention in women of childbearing age in rural Senegal

Tchadine Djaogol

Contact: tdjaogol@gmail.com

Background:

Perinatal transmission of hepatitis B virus (HBV) constitutes an important risk in highly endemic countries including Senegal. Although the prevalence of chronic HBV infection is estimated at 11% in this country, specific data on women of childbearing age are sorely lacking. We described in this study the prevalence of the HBV antigen (HbsAg) in women of childbearing age in rural Senegal, as well as general knowledge on HBV and hepatitis B status awareness.

Methods:

A cross-sectional study including HBV screening was conducted at home in the rural Niakhar area. Chronic HBV infection was determined through HBsAg detection using dried blood spots. Socio-demographic and behavioral data were collected through standardized face-to-face questionnaires. The analyzes included 368 women aged 15-49 (67% married; 65% with at least 1 child) enrolled from October 2018 to March 2019.

Results:

Preliminary results show that 49 women (13%) had positive HBsAg. Only 68 women (18%) have already heard about HBV. Among them, 53% knew that there exists an HBV vaccine and 78%, 75% and 67% correctly answered that HBV can be transmitted through blood contact, childbirth and sexual intercourse, respectively.

Among the 233 (63%) women who had already given birth, 76% had attended at least 4 antenatal care sessions and 74% had given birth in a healthcare facility for their last pregnancy. However, only 1% reported to have already been screened for HBV. Main reasons reported for not having been screened were having never heard about this test (80%) and not having been offered screening during antenatal care sessions (10%).

Conclusions:

General knowledge and awareness of HBV status are particularly low in women of childbearing age living in rural Senegal, despite high antenatal care sessions attendance. Given the high prevalence of chronic HBV infection found in this population, it is urgent to ensure systematic HVB screening and to provide adequate information to women during pregnancy.

Key messages:

- The prevalence of chronic HBV is high in women of childbearing age in Senegal.

- National recommendations for women attending antenatal care sessions should include HBV screening and counselling.

Perception of health risk linked to environmental factors by pregnant women

MP Sauvant-Rochat

M Sauvant-Rochat[1], NGL Kouamé[1], L Bernard[1], C Marie[1], D Lémery[2], F Vendittelli[2]
[1]UMR 6602, Université Clermont-Auvergne, CNRS, SIGMA Clermont, Institut Pascal, Clermont-Ferrand Cedex 1, France
[2]UMR 6602, Université Clermont-Auvergne, CHU Clermont-Ferrand, CNRS, Institut Pasca, Clermont-Ferrand, France
Contact: m-pierre.sauvant-rochat@uca.fr

Bacground:

Recently, the International Federation of Gyneco-Obstetrics (FIGO) advocates limiting exposure to chemicals present in everyday products during pregnancy. To date, the chemicals, and the risks related, are not well-known, as well by perinatal health professionals (PHP) as by pregnant women (PW). AIMS: to estimate the sensitivity to the environment and the perception of risks related to chemical substances by pregnant women.

Methodology:

A descriptive cross-over study was carried out among pregnant women ((followed or hospitalized in different health establishments in Auvergne). The collection of data (socio-demographic characteristics, sensitivity to the environment, use of cosmetics, perception of environmental risks) was carried out by interviewers, using a standardized questionnaire. The statistical analysis (logistic regression) was performed with Modalisa® 8.0 (Kynos, Paris).

Results:

Three hundred questionnaires were analyzed. The sensitivity to the environment is estimated at 6.3 ± 1.7 (scale 0 to 10). For the majority of women, exposure to chemicals is primarily related to the use of cleaning products, DIY products, and gardening products. Food can also be a source of exposure (especially for pesticides). On the other hand, cosmetics are not perceived as products containing chemical substances, with potential risk to health. This vision of chemical substances is related to age, educational level, socio-professional category and sensitivity to the environment. Only 5% (19/300) of PW considered health professionals as referents on chemical substances and environmental problems.

Conclusions:

This study highlighted the sensitivity of pregnant women to environmental issues, but a lack of knowledge of chemicals and the risks which they represent for health. It is important to reinforce the information given to pregnant women by perinatal health professionals about healthy behaviors.

Key messages:

- Pregnant women don't know all sources of exposure to chemical substances.
- Training in environmental health must be increased for perinatal health professionals.

Effect of smoking behaviour before and during pregnancy on Low head circumference at birth

Olga Kharkova

O Kharkova[1], J Odland[2]
[1]ISPHA, Arkhangelsk, Russia
[2]Norwegian University of Science and Technology, Trondheim, Norway
Contact: harkovaolga@yandex.ru

Background:

Smoking during pregnancy leads to adverse pregnancy and birth outcomes. Compared to the number of studies on low birth weight, the influence of maternal smoking on low head circumference at birth is not well documented. The aim of the study was to assess an effect of smoking behavior before and during pregnancy on low head circumference at birth.

Methods:

The study is based on the Murmansk County Birth registry. Our study includes women who delivered a singleton pregnancy after 37 weeks of gestation (N = 44,486). Smoking information was self-reported and assessed at the first antenatal visit during pregnancy. Low head circumference was defined in according to the World Health Organization as Mean value minus 2 standard deviations for girls and boys separately. Using logistic regressions we adjusted for maternal age, residence, ethnicity, education, marital status, alcohol abuse, year of delivery, body mass index, pregnancy diabetes, gestational age, and excessive weight gain.

Results:

A dose-response relationship was evident between the number of cigarettes smoked per day during pregnancy and the odds of low head circumference at birth (adjusted OR1-5 cig/day = 1.69 with 95% CI: 1.31-2.19; OR6-10 cig/day = 2.08 with 95% CI: 1.63-2.65; and OR $\geq$ 11 cig/day = 5.19 with 95% CI: 3.89-6.92). Compared to non-smokers, quitting smoking during the first trimester of pregnancy had no significant effect on low head circumference at birth (adjusted ORquitters = 1.04 with 95% CI: 0.80-1.34).

Conclusions:

Despite dose-response relationship was observed between maternal smoking and low head circumference at birth, women who stopped smoking during the first trimester were at no higher risk of having a baby with the low head circumference as compared to non-smokers. Our findings underline a continued need for actions against maternal smoking.

Key messages:

- women who stopped smoking during the first trimester were at no higher risk of having a baby with the low head circumference as compared to non-smokers.
- A dose-response relationship was evident between the number of cigarettes smoked per day during pregnancy and the odds of low head circumference at birth.

Does the over-medicalisation of pregnancy help to improve neonatal outcomes?

Claudia Cuccaro

L Kundisova[1], N Nante[1,2], C Cuccaro[1], E Mariottini[3], L Alaimo[3]
[1]Post Graduate School of Public Health, Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[2]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[3]Degree Course in Obstetrics, University of Siena, Siena, Italy
Contact: claudia.cuccaro@student.unisi.it

Introduction:

The over-medicalization of pregnancy is frequent, especially in high-income countries and comports unnecessary costs for health systems. In Italy the national health service guarantees access to health care services, but still a lot of pregnant women search for private health care. This study aimed to analyse if the over-medicalization of pregnancy had an impact on neonatal outcomes.

Methods:

The cross-sectional study was conducted in Siena (Italy), data were extracted from medical records. All women that gave birth between January 2016-May 2018 and were classified as ''low/moderate risk'' pregnancy were included. Examined variables were: age, number of obstetrics and ultrasound (US) visits ($\leq$9/$\geq$10), timing of the first visit (<12weeks/>12weeks of pregnancy), health facility (public/private), previous spontaneous abortions (SA) or voluntary interruptions of pregnancy (VIP). The outcome variables were preterm birth (PB) and admission in neonatal intensive therapy unit (NITU). Analysis was performed with Stata 12.

Results:

A total of 2392 women were included; 22% with$\geq$10 obstetrics visits; 19% with$\geq$10 US visits; 87% had the first visit before 12 weeks of pregnancy and 57% were followed by a private healthcare facility. Six percent of babies were born preterm and 11% were admitted in NITU. The PB condition appeared associated with SA (OR:2.4, 95%CI 1.6-3.6 $p < 0.001$) and VIP (OR:1.8, 95%CI 1.2-2.8 $p < 0.005$).

Admission in NITU was associated with previous VIP (OR:1.4, 95%CI 1.01-2.03 $p<0.05$) and PB (OR:2.16 95%CI 1.37-3.41 $p = 0.001$). Multiple logistic regression identified only PB as associated with this outcome.

Conclusions:

Neonatal outcomes do not show association with number of obstetric/US visits and the type of health facility. It seems that controlled pregnancy does not help to reduce the risk of adverse events as premature birth or admission in intensive therapy.

Key messages:

- The over-medicalization of pregnancy is frequent, especially in high-income countries and it has an important impact on health-related costs.
- More controlled pregnancy does not help to reduce the risk of adverse events as preterm birth and necessity of recovery in neonatal intensive therapy unit.

Maternal dietary patterns during early pregnancy and birth weight in Japan

Takahiro Yamashita

T Yamashita[1,2], Y Yonezawa[1,2], T Obara[1], M Ishikuro[1], T Usuzaki[1], K Murakami[1], A Noda[1], F Ueno[1], H Suganuma[2], S Kuriyama[1]
[1]Tohoku Medical Megabank Organization, Tohoku University, Sendai, Miyagi, Japan
[2]Innovation Division, Kagome Co., LTD., Nasushiobara, Tochigi, Japan
Contact: takahiro_yamashita@kagome.co.jp

Background:

The average birth weight in Japan has decreased by 200 g in the last 40 years. Only three studies were reported for the association between maternal dietary patterns and birth weight in East Asia, whose results were inconsistent. We examined what maternal dietary patterns were associated with the birth weight in Japan.

Methods:

Totally 22,493 pregnant women were recruited between July 2013 and September 2016 into the Tohoku Medical Megabank Project Birth and Three-Generation Cohort Study. We included 17,287 women who had a full-term single healthy baby into the analysis. Consumption of food and beverage items was evaluated based on food frequency questionnaire at the first-trimester. Dietary patterns were analyzed using a machine learning method of k-means clustering algorithm. Birth weight was obtained from the medical record. The association between dietary patterns and birth weight was analyzed using multiple liner regression model adjusted for potential confounders with multiple imputation method for missing values.

Results:

Dietary patterns were classified into seven groups by cluster analysis: ''high in rice (reference) ($n = 8046$)'', ''middle in vegetables, beans, mushrooms, seaweeds and miso-soup ($n = 4842$)'', ''high in fruits ($n = 1176$)'', ''high in bread, dairy and alcohol ($n = 1091$)'', ''high in meat and fish ($n = 1049$)'', ''high in coffee, black tea, soft drinks and confections (high in coffee) ($n = 585$)'', and ''high in vegetables, beans, mushrooms, seaweeds and miso-soup ($n = 498$)'' groups. In multiple liner regression models, birth weight was 22.6 g (95%CI: 0.1 to 45.2 g) heavier in ''high in fruits'' group than in reference group and 39.4 g (95%CI: 8.6 to 70.3 g) lighter in ''high in coffee'' group than in reference group. The other groups were not statistically significant.

Conclusions:

High consumption of fruits and high consumption of coffee, black tea, soft drinks and confections during early pregnancy were associated with increased and decreased birth weight, respectively.

Key messages:

- We found maternal dietary patterns during early pregnancy using a machine learning method of k-means clustering algorithm.
- We found maternal dietary patterns which associated with the birth weight in Japan.

Capacity Building in Nurturing Care in Serbia

Anđelka Grujičić

S Mladenovic Jankovic[1], D Matijevic[1], G Tamburkovski[1], A Grujicic[1], M Markovic[1]
[1]Institute of Public Health of Belgrade, Belgrade, Serbia
Contact: andjelka.grujicic@zdravlje.org.rs

Background:

Training program for home visitors on early child development was developed and implemented within UNICEF supported projects involving 25 primary health centers. Training content was notably based on resource modules ''Supporting Families for Nurturing Care'', adapted according to the local context. Health professionals are seen as the critical actors to support development of young children and their families. Family-centered approach that addresses social as well as medical dimensions of problems became priority in their practice with a special focus on working with children from socially deprived settings and children with disabilities.

Objectives:

The main objective was to improve knowledge and practice of home visitors on early child development based on most recent scientific evidence. Broad spectrum of topics was covered including engaging fathers, early detection of postpartum depression, attachment, developmental monitoring, age-appropriate play, home safety, stigma and discrimination. Training were organized as interactive face to face sessions and online courses and attendees were actively engaged in reflection. Comprehensive check list with various assessment instruments was developed to provide guidance to home visitors in implementation of gained skills.

Results:

Increase in knowledge of 150 home visitors was between 57.6% and 82.9%. Enhanced knowledge and skills have been applied in 14912 families of which socially deprived was 34.5% during 2-year period of implementation. Parent-child interactions, assessed by visiting nurses, were improved by 32.6%, responsive feeding practices by 27.4%, while age-appropriate play by 34.4% after interventions during home visits.

Conclusions:

Well-developed monitoring system was crucial for implementation of gained knowledge and skills in practice of home visitors.

Key messages:

- Home visitors were empowered to take a strengths-based approach in their work with families.
- Developed tools facilitated prioritization of most vulnerable families and tailoring support according to needs.

Breastfeeding-related social media: an online survey of UK mothers' perceptions

Shelina Visram

S Visram[1,2], T Hunter[1]
[1]Faculty of Medical Sciences, Newcastle University, Newcastle-upon-Tyne, UK
[2]Fuse (Centre for Translational Research in Public Health), Newcastle University, Newcastle-upon-Tyne, UK
Contact: shelina.visram@newcastle.ac.uk

Background:

Breastfeeding is beneficial for both maternal and infant health, contributing to reduced risk of infections and chronic disease. Despite public health efforts, just 1% of mother-infant dyads in the UK meet international recommendations to breastfeed exclusively until six months. Numerous studies have investigated the influences on suboptimal breastfeeding rates, exposing a myriad of interconnected physiological, psychological and social barriers. Conversely, social support has been shown to be positively associated with breastfeeding duration. The objective of this study was to determine whether and how

UK mothers use social media to access breastfeeding advice and support.

Methods:

An online survey was developed, piloted and distributed via social media using a snowball sampling approach. Responses to closed questions were analysed using SPSS and appropriate statistical tests performed. Free-text responses were analysed manually using thematic analysis.

Results:

The survey was completed by 1012 mothers, with 992 (98%) reporting use of social media for breastfeeding advice and/or support. Responses revealed a largely positive perception of breastfeeding-related social media. Supportive peer networks and easily accessible information were highlighted as unique features that help to encourage and normalise breastfeeding. Non-university educated mothers were significantly more likely to report this support as ‘‘very influential’’ with regard to how comfortable they felt breastfeeding in public (p = 0.006). Peer-led groups were preferentially used over professional-led groups, particularly by younger women (p = 0.007).

Conclusions:

There is growing interest in social media as a health platform, particularly in light of recent funding cuts impacting on access to formal support services. By supporting mothers and normalising breastfeeding, social media may help to increase UK breastfeeding rates and reduce health inequalities.

Key messages:

- Many mothers successfully use breastfeeding-related social media for information and support, with a preference for peer-led as opposed to professional-led groups.
- Future research should explore how public health services can update their practice to better harness these platforms for breastfeeding promotion.

6.S. Environmental health

Monitoring air pollution effects on children for supporting public health policies (MAPEC_LIFE study)

Elisabetta Ceretti

E Ceretti[1], *F Donato*[1], *D Feretti*[1], *A Carducci*[2], *M Moretti*[3], *A De Donno*[4], *E Carraro*[5], *A Biggeri*[6], *U Gelatti*[1]
[1]Unit of Hygiene, Epidemiology and Public Health, University of Brescia, Brescia, Italy
[2]Department of Biology, University of Pisa, Pisa, Italy
[3]Department of Pharmaceutical Sciences, University of Perugia, Perugia, Italy
[4]Dep of Biological and Environmental Science and Technology, University of Salento, Lecce, Italy
[5]Department of Public Health and Pediatrics, University of Torino, Torino, Italy
[6]Department of Statistic, Computing and Application, University of Firenze, Firenze, Italy
Contact: elisabetta.ceretti1@unibs.it

Background:

Children are at high risk of suffering health consequences of air pollution and childhood exposure can increase the risk of developing chronic diseases in adulthood. The MAPEC_LIFE project, funded by EU Life+ Programme (LIFE12 ENV/IT/000614), aimed to evaluate the association between air pollution exposure and biomarkers of early effect in children and to propose guidance for implementing environmental policies.

Methods:

The study was carried out on 6-8-year-old children. Micronucleus (MN) frequency was investigated in buccal cells of children and its association with air pollution exposure was assessed applying multiple Poisson regression mixed models, including socio-demographic and lifestyle factors as confounders. We also dichotomize air pollutants concentration according to the EU Ambient Air Quality Directives and WHO Air Quality Guidelines in all Poisson regression models to assess their risk predictive capacity.

Results:

The project involved 1149 children providing buccal cells in winter and spring. 2139 biological samples were included in the analysis (1093 collected in winter, 1046 in spring). The analysis of the association between MN frequency and air quality parameters found positive associations for PM10, PM2.5, benzene, SO2 and ozone. Considering EU Directives, an association was found between MN frequency and PM10 exposure higher than the annual limit value, with an increase of the risk of 17.9% (95%CIs: 0.6-38.1%). Considering WHO Guidelines, the exposures to levels of PM10, benzene and BaP higher than the annual limits were associated with MN frequency, with a risk increase of 22.5%, 27.8% and 59.8% (95%CIs: 3.9-44.3%, 3.8-57.3%, 21.0-111.1%), respectively.

Conclusions:

The analyses conducted showed an association between MN frequency in buccal cells of children and levels of some air pollutants, even at concentration below EU and WHO thresholds, which hence seemed to be insufficient for protecting children from this type of damage.

Key messages:

- Air pollution exposure induced chromosomal damage in buccal cells of children, even at concentration below the law limits.
- Early biological damage detected might be predictive of the occurrence of future harmful effects in humans, at a population level.

Neighborhood disparities in stroke and socioeconomic, urban-rural factors using stroke registry

Cindy Padilla

C Padilla[1], *O Grimaud*[1], *E Nowak*[2], *S Timsit*[3]
[1]University Rennes, EHESP, REPERES, EHESP, Rennes, France
[2]Centre d’Investigation Clinique, INSERM CIC 1412, Brest, France
[3]Service de Neurologie et Unité Neuro-Vasculaire, CHRU, Brest, France
Contact: cindy.padilla@ehesp.fr

Introduction:

Despite major improvements in management over recent decades, stroke remains a devastating disease in Europe and geographic disparities persist. Determining the spatial distribution of stroke may be useful for both epidemiological research and health services planning. The aim of this study was to estimate stroke incidence rates in Pays de Brest (Western France) and to explore the presence of geographic clusters associated with socioeconomic and urban-rural characteristics.

Methods:

The study included incidence stroke cases aged 60 years and more from the Stroke Brest registry for the period 2008 to 2013 aggregated at the census block level. Poisson and negative binomial regression models were used to explore determinants of disease risk. Geographically weighted regression (GWR) was used to allow estimation of local regression coefficients.

Results:

Between 2008 and 2013, 3088 cases aged 60 years were identified in Pays de Brest. The incidence of stroke was 6.67 per 1 000 inhabitants. Living in a rural neighborhood with a higher level of blue collar and of farmer was associated with higher age adjusted stroke incidence rate ratio (IRR) 1.23, [95%CI 1.09-1.39]. Higher risk was also found in a city center neighborhood with a higher level of blue [IRR 1.22, 95%CI 1.04-1.49]. Local Poisson GWR models achieved the best fit and suggested evidence of spatially varying regression coefficients and clusters of higher incidence.

Conclusions:

Our study contributes to a better understanding of the relationship between stroke risks and contextual characteristics such as socioeconomic circumstances and urban rural setting. This will help targeting areas for specific public health prevention.

Key messages:

- Variations of stroke were marked according to socioeconomic and urban-rural setting of the living area.
- This study will help targeting areas for specific public health prevention.

Individual and process factors influencing user's satisfaction with Housing First services

Sandrine Loubiere

S Loubiere[1,3], A Tinland[2], M Boucekine[1,3], V Girard[3], P Auquier[3,1]
[1]APHM, Marseille, France
[2]MARSS, APHM, Marseille, France
[3]CEReSS, AMU, Marseille, France
Contact: sandrine.loubiere@univ-amu.fr

Objectives:

Housing First models aim to give homeless with severe drugs and mental health problems a permanent home and assertive care team support. Concern persists that user satisfaction and retention rate are key values in the evaluation of such inclusive-care programs, to secure good outcomes. The aims of this study were 1) to explore user's satisfaction with Housing First services, and 2) to determine individual or contextual factors influencing user's satisfaction.

Methods:

Based on the French Un Chez Soi d'Abord sample, we analysed data from homeless people with severe mental problems assigned to the Housing First and followed during 3 years. Measures included team tracking frequency, service users' needs, and a Client Satisfaction Questionnaire (CSQ-8). Generalized estimating equations were used with a random effect for site to identify relevant baseline confounders for the CSQ score.

Results:

At 36-month follow-up, 131 HF participants completed the services user's needs and CSQ-8 questionnaires. 94% were still housed. Respondents reported needs from the HF team for managing housing (74%), administrative assistance (63%) and mental illness (43%). The mean total CSQ-8 score was 25.6 (SD = 5.2) out of 32. Four predictors of a higher CSQ score were: higher frequency of visits (regression coefficients 8.2), lower user's education (-2.2), ever been a tenant (1.4), and suffering of schizophrenia disorder (0.9) (p<.001).

Conclusions:

The users' perception of the quality of HF services appears to be high. Our results underscore the interaction of individual and process factors influencing user satisfaction. These findings suggested that HF intervention in France is a promising strategy for high quality of services to homeless people with mental illness.

Key messages:

- He users' perception of the quality of Housing First services appears to be high.
- Housing First intervention in France is a promising strategy for high quality of services to homeless people with mental illness.

Comprehensive unhealthy lifestyle is associated with alcohol consumption as J-shaped curve

Ippei Shimoshikiryo

I Shimoshikiryo[1], R Ibusuki[1], K Shimatani[2], D Nishimoto[1], T Takezaki[1], K Wakai[3], J-MICC Study Group
[1]Department of International Island and Community Medicine, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan
[2]Department of Nursing, Tokyo Healthcare University Postgraduate School of Nursing, Tokyo, Japan
[3]Department of Preventive Medicine, Nagoya University Graduate School of Medicine, Nagoya, Japan
Contact: ippei.35sh@gmail.com

Background:

Alcohol consumption is a confirmed risk factor for cancer as well as cardiovascular and other diseases. Decreased and increased risks with light and heavy consumption, respectively (J-shaped associations), were reported for total mortality. However, whether alcohol itself or its related-factors are involved in this association, is unclear. This study examined the background characteristics of comprehensive lifestyles and clinical factors according to alcohol consumption, using data from a baseline survey of large-scaled cohort study conducted among the general Japanese using Breslow's healthy lifestyle index.

Methods:

The study subjects were 23,885 males and 28,165 females aged 35 to 69 years, who were enrolled in the Japan Multi-Institutional Collaborative Cohort (J-MICC) Study. To determine unhealthy lifestyle scores, smoking, exercise, sleeping duration, breakfast consumption, eating between meals, and obesity were combined. The odds ratios (ORs) of unhealthy lifestyles and clinical factors according to alcohol consumption were estimated using a logistic regression model.

Results:

The ORs of combined unhealthy lifestyles decreased among light drinkers in males (0.73, 0.67-0.80) and females (0.88, 0.82-0.95), and increased among heavy drinkers (1.52, 1.27-1.83; 2.15, 1.44-3.20, respectively). These associations were not found for each unhealthy lifestyle and atherosclerosis-related factors, except for less breakfast intake in males and less frequent habitual exercise in females.

Conclusions:

The present study suggests that the J-shaped association between comprehensive unhealthy lifestyle and alcohol consumption may be an important background factor of the association between alcohol consumption and risk of total mortality. Further study for total mortality with them is warranted.

Key messages:

- This study showed comprehensive unhealthy lifestyles were observed not only among heavy drinkers, but also among non-drinkers.
- Light drinkers have more healthy lifestyles, which contribute to their better health.

Prenatal exposure of extra vitamin D from fortification and later risk of inflammatory bowel disease

Katrine Sidenius Duus

KS Duus[1,2], CM Moos[1,2], P Frederiksen[1], V Andersen[2,3], BL Heitmann[1,4]
[1]Research Unit for Dietary Studies, Parker Institute, Bispebjerg and Frederiksberg Hospital, Copenhagen University Hospital, Copenhagen, Frederiksberg, Denmark
[2]Research Unit for Molecular Diagnostic and Clinical Research, IRS-Center Soenderjylland, University Hospital of Southern Denmark, Aabenraa, Denmark
[3]Institute of Molecular Medicine, University of Southern Denmark, Odense, Denmark
[4]Department of Public Health, Section for General Practice, University of Copenhagen, Copenhagen, Denmark
Contact: katrinesideniusduus@gmail.com

Introduction:

Inflammatory bowel disease (IBD) is a chronic immune-mediated inflammatory disease that can affect the entire digestive tract. Approximately 1% of the Danish population has IBD today. Both the incidence and prevalence of IBD are increasing globally, but the etiology of IBD is still not fully understood. Some, but not all studies find that vitamin D has both protective and therapeutic effects on IBD. To our knowledge, no other study has investigated prenatal exposure to extra vitamin D from either fortified food, diet or supplements in relation to IBD. The aim of this study was to investigate whether a small extra dose of vitamin D from fortification during gestation, was associated with a lower risk of developing IBD in the offspring.

Methods:

In 1985 mandatory fortification of margarine with vitamin D in Denmark was canceled. To investigate the effect of this policy change we selected all individuals from 2 full year birth cohorts before and after the termination of the mandatory fortification. All individuals were followed for 30 years. By merging data from the Medical Birth Registry with the Danish National Patient Registry, we identified individuals with IBD.

Results:

217,249 individuals were included in the analysis. 875 among the exposed and 1102 among the unexposed fulfilled the criteria for being diagnosed with IBD. A lower odds ratio OR = 0.867 (95% CI: 0.792;0.947) for IBD was observed among those who had been exposed to extra vitamin D from fortified margarine during gestation, compared to those who had not been exposed. The analysis was adjusted for sex and season of birth, but results were essentially similar before and after this adjustment.

Conclusions:

This study shows, that a small extra dose of vitamin D from fortified margarine during gestation may lower the risk of developing IBD in the offspring, until the age of 30. If these results can be replicated, fortification with vitamin D could be recommended to prevent IBD on a public level.

Key messages:

- Prenatal exposure of vitamin D from fortified food could lower the risk of IBD later in life.
- Fortification with vitamin D even at a relatively low level could have public health benefits.

Individual-level high definition spatial distribution of mammography uptake in Geneva (Switzerland)

José Luis Sandoval

JL Sandoval[1,2], *R Himsl*[1,2], *S Joost*[1,2], *I Guessous*[1,2]
[1]Unit of Population Epidemiology, Geneva University Hospitals, Unit of Population Epidemiology, Geneva, Switzerland
[2]GIRAPH Lab, Geneva University Hospitals, Geneva and Ecole Polytechnique Fédérale de Lausanne (EPFL), Geneva and Lausanne, Switzerland
Contact: jose.sandoval@cantab.net

Background:

The local social and physical environment influences health outcomes and individual behaviour. It remains unknown if the environmental influence is independent of individual socioeconomic status (SES). We studied the spatial distribution of mammography screening uptake in the Swiss urban population of Geneva and determined its independence from SES.

Methods:

We used individual-level geo-referenced data (n = 5 002) from the participants in the Bus Santé study, a population-based cross-sectional study ongoing in Geneva since 1992. Data from 1992 to 2014 have been included in this study. Local indicators of spatial association (LISA) were calculated and used to assess the spatial dependence of mammography uptake (defined as having had a mammography in the past). We report unadjusted spatial clusters; adjusted for neighbourhood income and individual educational attainment; and for demographic variables (age and Swiss nationality). Furthermore, we evaluated the association between the distance to the nearest screening centre and the identified spatial clusters.

Results:

Mammography uptake was not randomly distributed, with spatial clusters overlapping with those of SES. Spatial clusters were reduced to 56.2% of their initial size (n = 1,033) after adjustment for SES variables. Adjustment for age and nationality further reduced the proportion of individuals exhibiting spatially-dependent behaviour (to 36.5% of the initial size). Distance to the nearest screening centre was not associated with the spatial distribution of mammography uptake.

Conclusions:

High definition spatial distribution studies using analysis of individual data allow identifying spatial clusters which are not based on pre-determined administrative units (e.g. postal code) but rather on individual behaviour. Persistent spatial clusters after adjustment for SES and demographic confounders suggest additional area-level determinants influencing the spatial distribution of mammography uptake.

Key messages:

- High definition spatial studies can help uncover new patterns of health outcomes distribution independent of SES and based on individual behaviour, rather than administrative units.
- While SES explains a great proportion of the spatial distribution of mammography uptake, other still elusive factors may be contributing to the observed spatial inequalities in mammography uptake.

Prognostic and Predictive biomarkers in a Mediterranean cohort (Review from Atena Project)

Fabiana Rubba

F Rubba[1], *M Gentile*[1], *MS Scamardo*[1], *G Iannuzzo*[1], *C Panico*[1], *M Pacilio*[1], *G D'Onofrio*[1], *S Panico*[1], *P Rubba*[1], *M Triassi*[1]
[1]AOU Federico II, Naples, Italy
Contact: fabiana.rubba@unina.it

Background:

Atena project involved 5,062 women aged 30 to 69 years living in the area of Naples. The purpose of this study is to investigate the causes of those chronic diseases that have a major impact on the female population. As a part of the design (scheduled in 2002-2004). After 10 years, in 228 women, some biochemical measurements were performed.

Methods:

This systematic review and meta-analysis biomarkers were evaluated in studies nested into the Atena cohort. Studies were searched using MEDLINE/PubMed. The search was performed by entering individually or in combination: Atena, Mediterranean woman, biomarkers. The preferred reporting of systematic reviews and meta-analysis (PRISMA) guidelines were used for the review. Studies selected for this review are conducted in the Atena project Cohort and reported the study of biomarkers. Disagreements on data extractions between the two investigators were solved by consensus. The extracted data were entered and analyzed using REVMAN software. The original articles were described using forest plot and table. Heterogeneity was computed by Cochran's Q test.

Results:

The search strategy retrieved 13 potential articles, 11 were screened as full text articles and 6 were included in the pooled estimates. Among the articles included, biomarkers chosen as predictors were Lipids, Hcrp, as prognostic where predictive of IMT; and cycle length and LPa as predictive of an augmented LDL cholesterol mean. According to the comparability of data presented, for the first comparison we selected 3 of the 5 studies that assed IMT, for the second we selected 2 of the three studies that analyzed for LDL mean. Results were shown into forrest plots. The pooled estimates verified the potential of biomarkers as predictor of IMT, the significance seemed lower for prediction of LDL cholesterol.

Conclusions:

Both results, consistent with the multifactor profile of the CV risk, identify the impact of secondary prevention according to biochemical profiles.

Key messages:

- Biomarkers studied in nested cohort stufies have predictive potential.
- pooled estimates may identify the impact of secondary prevention according to biochemical profiles.

Against lead poisoning: effectiveness of housing first and counselling in the home

Remi Laporte

R Laporte[1]*, H Barberin de Barberini*[2]*, E Jouve*[2]*, K Hadji*[3]*, S Gentile*[2]
[1]PASS Mèr-Enfant, Assistance Publique - Hôpitaux de Marseille, Marseille, France
[2]CEReSS - EA 3279, Aix Marseille Université, Marseille, France
[3]Département Santé Environnement, Agence Regionale de la Santé PACA, Marseille, France
Contact: remijulien.laporte@ap-hm.fr

Background:

Removing lead sources is the main measure against child lead poisoning. Medical treatment is ineffective for most mild cases and particularly against long-term complications in neurological development. However, the effectiveness of interventions to eliminate sources of lead exposure has not been fully established, mainly because of the diversity of situations. The objective of this study was to determine the influence of several interventions (housing counselling, rehabilitation and relocation) on blood lead levels in two situations (stable unhealthy housing with old flaked lead paints, slums with family recycling practices by incineration).

Methodology:

A historical cohort of lead poisoning in children has been established in Marseille, France. Medical follow-up followed national guidelines. Environmental interventions followed legal procedures, where available. In slums, counselling was adapted to the exposure. A generalized mixed model was developed to study the kinetics of blood lead levels after the interventions.

Results:

151 children were included; age = 5.4 (SD = 7.8) years; 85 (56%) lived in stable unhealthy housing, others lived in slums. Medical follow-up included 492 blood lead levels. For children living in stable unhealthy housing, blood lead level decrease was significantly associated with every intervention: housing counselling, rehabilitation and relocation (respectively $p < 0.005$; $p < 0.05$ and $p < 0.005$). For children living in slums, blood lead level decrease was only associated with relocation in a stable housing ($p < 0.005$).

Conclusions:

Several interventions are effective to decrease blood lead levels in unhealthy housing. In slums, access to a stable housing first is a prerequisite for any intervention against child lead poisoning, even when related to family practices.

Key messages:

- In stable unhealthy housing, several interventions against lead exposure can be effective to raise a strategy.
- But, environmental health and access to housing first needs to be addressed for their implementation.

7.R. Health systems and economics

The Public Health Implications of Brexit: A Health Impact Assessment Approach

Liz Green

L Green[1]
[1]Public Health Wales, Wrexham, UK
Contact: liz.green@wales.nhs.uk

On March 29th 2019, the United Kingdom (UK) was due to exit the EU in a process known informally as 'Brexit'. This exit and entry into a 2-year transition is a period of unprecedented political and social upheaval - with many unknowns and much uncertainty attached to the outcomes and future impact.

In preparation for Brexit, Public Health Wales commissioned the Wales HIA Support Unit to carry out a health impact assessment of Brexit in Wales to support and inform its and other public bodies planning and future work.

This paper examines the unique HIA carried out between July and December 2018 on the impact of the UK withdrawal from the EU in Wales. It discusses the robust, participatory process undertaken, the stakeholders involved and the benefits reaped from this. It highlights the evidence gathered and analysed including the collection methods, the complex nature of the work and disseminates the main findings from the HIA including the potential determinants of health and population groups identified.

Finally, it describes the challenges faced, how these were overcome, and the huge benefits, impact and influence it has had to date across a wide range of UK and Welsh organisations and public bodies. This work demonstrates continued leadership in the field of impact assessment and spearheads the requirement for public bodies to carry out HIAs as part of the forthcoming statutory requirements of the Public Health (Wales) Act 2017 an can inform practice at a global level.

Key messages:

- HIA can inform and influence action in response to important strategic decisions.
- The Brexit HIA is a unique example which can inform international HIA practice.

Unpaid carer inequalities: a public health concern

Susan Carr

S Carr[2,3]*, A Woklowski*[1]*, M Parkinson*[2]
[1]Dove House Hospice, Hull, UK
[2]Faculty of Health & Life Sciences, Northumbria University, Newcastle upon Tyne, UK
[3]Fuse, Centre for Translational Research, Newcastle upon Tyne, UK
Contact: sue.carr@northumbria.ac.uk

The number of unpaid carers is rising globally and is anticipated to grow given predictions on life expectancy, morbidities and limitations on care alternatives. The estimated number in England is 5.5 million. Significant international evidence exists of potential negative impact on employment, health and wellbeing which have individual and societal consequences. This presents a major public health concern, especially as much of the experience and health consequences remain a largely hidden issue.

Drawing on two doctoral studies undertaken in the UK we expose the potential for significant health and social inequalities to be experienced by unpaid carers and offer models to enhance understanding and potentially more effective responses. The presenting author provided supervision and continues to research the topic.

Both studies were set in a translational paradigm to maximise timely utility. The experiences of the participants were privileged while attempting to ensure that the clinical, education and policy potential of the research was incorporated. Study participants were care givers for family members with life limiting illnesses, principally cancers and dementia. Qualitative methodologies were employed in both studies; one drawing significantly on realist approaches and the other on grounded theory.

There is generally a lack of consensus concerning when and how carers can best be supported. Although some support interventions were valued there are some fundamental tensions in service models which limit their potential. Specifically the centrality of the relationship is needs to be acknowledged and nurtured. Often, professionals often predominately draw on a medical model as the default intervention position when attempt to tackle carers' health inequalities. These findings suggest that greater attention should be afforded to the potential of social coping strategies to create a more enabling rather than burden dominated perspective.

Key messages:

- unpaid (family)carers are at risk of being exposed to a range of health inequalities which can have individual and societal consequences.
- Interventions that acknowledge the relationship and draw on social dimensions may off coping may offer effective ways forward.

Shifting the Gravity of Spending: Assessing the impact of PHE's Prioritisation Framework

Gregory Maniatopoulos

G Maniatopoulos[1], *D J Hunter*[1], *J Gray*[2]
[1]Institute of Health and Society, Newcastle University, Newcastle upon Tyne, UK
[2]Health and Life Sciences, Northumbria University, Newcastle upon Tyne, UK
Contact: gregory.maniatopoulos@ncl.ac.uk

Background:

Findings are presented from the evaluation of Public Health England's (PHE) new Prioritisation Framework (PF) conducted between September 2017 and December 2018 aimed to help local authority commissioners with their public health investment and disinvestment decisions. The study explored the take up of the PF in three early adopter local authority settings.

Methods:

Data collection was based on semi-structured interviews (n = 30) across three local authorities supplemented by participant observation of workshops and data concerning the implementation process as well as spend and outcomes both before and, where possible, after using the PF.

Results:

Participants acknowledged that the PF provided a systematic way to guide prioritisation decisions and one that encouraged transparency over investment and disinvestment decisions. The role performed by PHE and its regional teams in facilitating the process was especially welcomed and considered to be critical to the adoption process. However, uptake of the PF required a significant investment of time and commitment from public health teams at a time when resources were stretched. The impact of the political environment in local government was a major factor determining the likely uptake of the PF. Ensuring committed leadership and engagement from senior politicians and officers was regarded as critical to success.

Conclusions:

The study assessed the value of the PF and the processes surrounding its implementation and use. Further research could further explore the value of the tool in aiding investment and disinvestment decisions and its impact on spending.

Key messages:

- The PF provides a platform for engaged and informed deliberation about priorities and does so in an open, structured and transparent manner.
- Organisational and political context in which prioritisation occur shape the adoption of the PF tool.

Determinants of frequent use of primary care in the German healthcare system

Alexander Rommel

A Rommel[1]
[1]Robert Koch-Institute, Berlin, Germany
Contact: RommelA@rki.de

Background:

In Germany, patients are consulting general practitioners increasingly frequently, resulting in a high burden on the healthcare system. This study aimed to identify factors associated with frequent primary care attendance in the German healthcare system.

Methods:

The German Health Interview and Examination Survey for Adults (DEGS) is part of Germany's national health monitoring, and includes a large representative sample of the German population aged 18-79 years. We defined the 10% of participants with the highest number of physician contacts in the preceding 12 months as frequent attenders. Binary logistic regression models with average marginal effects were used to identify determinants for the frequent use of primary care services.

Results:

The sample comprised 7,956 participants. Significant effects on frequent use of primary care were observed for low socio-economic status, stressful life events, and factors related to objective need for medical care and subjective health status. In the full model, the number of non-communicable diseases and subjective health status had the strongest effect on frequent primary care use. We found an interaction effect between subjective health status and number of non-communicable diseases, indicating the association of disease with frequent use was highly moderated by subjective perception of health.

Conclusions:

We observed strong associations between frequent primary care attendance and objective and subjective health-related factors. These findings suggest that better coordination of care may be a preferred method to manage health services utilization behaviour and avoid redundant examinations and uncoordinated clinical pathways. Further research is needed to clarify moderating and mediating factors contributing to high utilization of primary care services.

Key messages:

- The number of NCDs diseases and subjective health had the strongest effect on frequent primary care use.
- The findings suggest that better coordination of care may be the preferred method to manage health services utilization.

Does the take up of public insurance programs improves health care consumption of poor individuals?

Benoît Carré

B Carré[1,2], *M Thomas*[1], *F Jusot*[2,3], *J Wittwer*[4], *C Gastaldi-Ménager*[1]
[1]Department of Studies on Patients and Diseases, French National Health Insurance, Paris, France
[2]Leda-Legos, Paris Dauphine University, Paris, France
[3]Institute for Research and information in Health Economics, Paris, France
[4]Bordeaux Population Health Research Center, Univerty of Bordeaux, Inserm UMR 1219, Bordeaux, France
Contact: benoit.carre@assurance-maladie.fr

Background:

The French health insurance system is universal but 95% of the population is also covered by a complementary private health insurance (CHI). The CHI take up is not uniform across the income distribution and health care access is partly conditioned by its coverage. The Complementary Universal Health Coverage (CMU-C) and the Health Insurance Vouchers Scheme (ACS) are mean tested programs providing CHI to the poor. The former is free while the latter takes the form of a voucher to buy private CHI. Our objective is to study and compare the evolution of health care use and consumption associated with the take up of the CMU-C or the ACS.

Methods:

In a nationwide cohort of ACS and CMU-C beneficiaries we compute bi-annual expenditures, out of pockets expenditures and rates of use for different types of care: outpatient, inpatient, dental, optical and audiology. We use panel data regression methods to model the evolution of health care use and expenditures before, during and after the coverage periods of both programs.

Results:

Our population is composed with about 10 million individuals benefiting at least once from either the ACS or the CMU-C on the 2012-2017 period. Preliminary results suggest that inpatient expenditures are increasing concomitantly with the take up of any program whereas outpatient expenditures tend to increase after. Results will be provided for the conference on the variations of the consumption according to the program

(CMU-C or ACS), type of care, individual characteristics and health status.

Conclusions:

Free or subsidized complementary health insurance may play an important role in the access to care for poor population, even in the presence of mandatory coverage. The take up of complementary health insurance for the poor population could be partly driven by the use of inpatient services but coverage may impact positively outpatient expenditures.

Key messages:

- Unlocking poor individuals financial constraint tends to increase their use of medical services.
- Generous insurance coverage targeting financially constrained individuals could be a tool to reduce health care use inequalities.

Evaluation of polypharmacy in Japan using the national health insurance claims database in 2015-2017

Jinsang Park

JS Park[1], T Okui[1], H Furuhashi[1], S Tokunaga[1], N Nakashima[1]
[1]Medical Information Center, Kyushu University Hospital, Fukuoka, Japan
Contact: park21@med.kyushu-u.ac.jp

Background:

There is growing awareness of polypharmacy as a global issue. Several countries have introduced policies to optimize multidrug prescriptions. In Japan, hospital prescription fee ‘‘F100’’ and outpatient prescription fee ‘‘F400’’ have been instituted to promote the correct use of drugs, the medical treatment fee is restricted when seven or more types of drugs are prescribed. However, non-polypharmacy patients who need multiple drugs are also comprehensively evaluated within the purview of the same drug insurance claim criteria. Thus, the current state of such policies is still unclear. This study identified the age group in which drug claims have changed based on drug insurance claim criteria and elucidated the relationship between policy interventions and multidrug prescriptions.

Methods:

We analyzed F100 and F400 cases using open data from the National Database of Health Insurance Claims and Specific Health Checkups of Japan from April 2015 to March 2017. These sources include a population of about 69 million patients. Moreover, the growth rate of the number of patients who were prescribed seven or more types of drugs was evaluated.

Results:

F100 prescription claims decreased by − 12.7% (n = 3,239,070) in 2016 as compared to 2015 (n = 3,700,396), and the number of F400 prescription claims decreased by − 7.7% (n = 28,745,468) in 2016 as compared to 2015 (n = 31,142,484), for seven or more types of drugs. The drug insurance claim rate among people over the age of 65 was 74.2% to F100 and 77.9% to F400, and this age group represented the highest proportion among all age groups.

Conclusions:

The rate of health insurance claims for multidrug prescriptions clearly decreased after the institution of policy interventions to optimize the use of seven or more types of drugs. The present study suggests that the prescription fee restriction could reduce the rate of multidrug prescriptions and consequent decreases the risk of adverse drug-related events in polypharmacy patients.

Key messages:

- Policy interventions related to the optimization of drug prescriptions encourage behavioral factors of healthcare providers.
- Polypharmacy treatment must be established through prescriptions information linkage between clinical practices and community.

Unmet dental health care needs among adults in Serbia, Survey on Income and Living Conditions 2017

Jovana Todorovic

Z Terzic-Supic[1], J Todorovic[1], K Vojvodic[2], P Piperac[3], M Santric-Milicevic[1]
[1]Institute of Social Medicine, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[2]Institute of Public Health of Belgrade, Department for Planning,Organizing and Analyzing Health System, Belgrade, Serbia
[3]Department of Humanities, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
Contact: jovana.todorovic@med.bg.ac.rs

Background:

Changes in the health insurance law in 2005 led to the changes in the organization of the provision of dental health care in Serbia. Prior to this law, dental health care was available for every resident covered by mandatory health insurance without additional out-of-pocket payments. Now the dental health care is available only for children under the age of 18, students under the age of 26, pregnant women and for emergency dental care. The aim of this study was to assess the prevalence of unmet dental health care needs among adults and to assess the factors associated with unmet dental health care needs.

Methods:

The study was the secondary analysis of the data from the Survey on income and Living conditions in Serbia, conducted during 2017. Multivariate logistic regression analysis was used to assess the association of unmet dental health care needs and socio-demographic and socio-economic factors.

Results:

Total of 1718/12437 (12.1%) adults reported unmet dental health care needs. The main reason reported was not being able to afford it (1014/1718, 59.0%), along with the fear of doctors or hospitals (260/1718, 15.5%). Multivariate logistic regression analysis showed the association of unmet dental health care needs and being employed (OR: 1.50, 95% CI: 1.24-1.80), unemployed (OR: 1.96, 95% CI: 1.65-2.33), having primary (OR: 1.47, 95% CI: 1.16-1.86), or secondary education (OR: 1.43, 95% CI: 1.21-1.69), being divorced (OR: 1.47, 95% CI: 1.17-1.85), having good (OR:1.44, 95% CI: 1.20- 1.74), average (OR: 2.36, 95% CI: 1.91-2.92), poor (OR: 2.29, 95%CI: 1.77-2.97), or very poor general health (OR: 2.42, 95% CI: 1.68-3.48), having limitation in daily activities (OR: 0.66, 95% CI: 0.60-0.77) and being materially deprived (OR: 1.67, 95% CI: 1.46-1.90).

Conclusions:

The prevalence of unmet dental health care needs in high among adults in Serbia. There is an association between social characteristics and health status with unmet dental health care needs in Serbia.

Key messages:

- There is a high prevalence of unmet dental health care needs in Serbia.
- Unmet dental health care needs are associated with social characteristics and health status.

Atlases of variation for elective surgery to tackle wasteful care

Brigitte Piso

B Piso[1], V Buhmann[1]
[1]Austrian National Institute for Quality in Healthcare, Austrian Public Health Institute, Vienna, Austria
Contact: brigitte.piso@goeg.at

Background:

In 2017, the OECD suggested robust information systems as one of five measures to tackle wasteful care. Atlases of variation identify variations that may not be medically justified. The aim of this study was twofold: 1. to identify atlases that target variations in the provision of elective surgery and 2. to analyse the interventions that have been addressed.

Methods:

We conducted an online search for atlases of variation on websites and by a selective literature search in PubMed. When necessary, we contacted public health institutes to retrieve further information. We included online and/or paper-based atlases that analysed data on elective surgery. Other atlases (e.g., epidemiological) were excluded. We transferred basic (e.g., on country, language and methods) and specific information on analysed interventions into a predefined data extraction scheme.

Results:

We identified 12 international atlases that fulfilled our inclusion criteria (2 from Germany, 1 from Belgium, France, Great Britain, Norway, The Netherlands, Switzerland, Spain, Australia, New Zealand and the US). In addition to reports/factsheets, 9 atlases provide additional interactive online applications. In total, about 70 different surgical interventions have been analysed, most often the following: Interventions to treat diseases of the musculoskeletal system (11 atlases: e.g.; knee (9), hip (7) and spinal (4) surgery), diseases of the digestive system (9 atlases: e.g., appendectomy (6), cholecystectomy (6), bariatric surgery (4)), diseases of the genitourinary system (8 atlases: e.g., prostatectomy (6), hysterectomy (5)), caesarean sections (8 atlases).

Conclusions:

Despite the large number of interventions, their pattern of analyses might point out known problem areas across countries. Atlases of variations cannot solve the problem of inappropriate care, but help prioritise areas of actions with the greatest need and the best chances to improve the quality of care.

Key messages:

- Atlases are commonly used to provide publicly available information on variations in elective surgery.
- The analysis of interventions across countries provides information on potentially most relevant areas.

Pay for performance scheme for general practitioners in France: results in 2018

Alice Atramont

AA Atramont[1], SC Coffy[1], SS Sebo[1], GD Debeugny[1]
[1]Caisse Nationale d'Assurance Maladie (CNAM), Paris, France
Contact: alice.atramont@assurance-maladie.fr

Methods:

A pay-for-performance scheme, known as Remuneration on public health objectives (ROSP) and based on meeting targets on quality and efficiency indicators, was introduced for general practitioners in France in 2012. Since 2017, following the 2016 medical agreement between Health Insurance and doctors' unions, ROSP has consisted of 29 indicators: 8 about chronic disease management, 12 about prevention and 9 about appropriate and efficient prescriptions. The aim of this work was to describe the 2018 results and the overall evolution of the indicators for office-based practitioners. Data are from the French national health system database.

Results:

Follow-up of diabetic patients is steady: diabetic retinopathy screening and regular HbA1c measurement have been performed in 63% and 79% of them since 2016, respectively. Screening for chronic kidney disease improved for diabetic patients (29% in 2015 to 39% in 2018) and hypertensive patients (6% to 11%) but remain low. Influenza vaccination among people over 65 years increased in 2018 (55%) while a downward trend has been observed since 2011 (58% in 2011, 53% in 2016). The number of antibiotic treatments has decreased since 2011, from 46 out of 100 adults without long-term disease to 36 in 2018. In contrast, breast cancer and cervical cancer screening indicators have stagnated for several years around 66% and 56%, respectively. In terms of efficiency, all the indicators improved, most of them consisting in biosimilar and generic drugs prescription. By 2018, ROSP represents 3% of doctors' revenue (including fee-for-service and lump sum payments).

Conclusions:

By promoting prevention, better management of chronic diseases and optimizing prescriptions in relation to standards, ROSP indicators contribute to improve medical practices. The indicators need to be regularly updated to take into account the evolution of practices and recommendations.

Key messages:

- By promoting prevention, better management of chronic diseases and optimizing prescriptions in relation to standards, ROSP indicators contribute to improve medical practices.
- The indicators need to be regularly updated to take into account the evolution of practices and recommendations.

Cost-effectiveness analysis of the Un Chez Soi d'Abord randomized controlled trial: a Markov model

Sandrine Loubiere

C Lemoine[1], S Loubiere[1,3], A Tinland[2,3], M Boucekine[1,3], P Auquier[1,3]
[1]Service Epidemiologie et Economie de la Santé, APHM, Marseille, France
[2]MARSS, APHM, Marseille, France
[3]CEReSS, AMU, Marseille, France
Contact: sandrine.loubiere@univ-amu.fr

Objectives:

Providing permanent supported housing (rent subsidies), integrating clinical and social services to homeless people may represent a financial barrier for building a healthier European public policy. Our objective was to conduct a cost-effectiveness analysis of the French Housing First program.

Design and methods:

Between 2011 and 2014, homeless people with severe mental illness from 4 French major cities were randomized to Housing First (HF, n = 353) or Treatment as Usual (TAU, n = 350) and followed over 24 months. Housing stability and survival were assessed. Costs incurred by health (ED visits, hospital admissions, physician consultations), social (shelters, supported accommodations, other residential structures), justice services (court appearances, detention and penitentiary centres), and welfare benefits were collected over 24 months. Markov models of 6-month transition probabilities were compared among HF group (offering an independent house and support from outpatient mental health and social team) and TAU group (receiving pre-existing dedicated homeless-targeted programs and services). Three Markov states were defined: stable housing (at least 90 nights in an independent housing), unstable housing (i.e. inverse) and death. A societal perspective and a life-time horizon were chosen. Robust sensitivity analyses were performed, including Tornado diagram and Monte-Carlo simulations.

Results:

There is evidence of changes (P<.001) in housing stability (246% more days housed) for the HF group compared with TAU group. From the societal perspective, HF was €10,163 (3%) more costly than usual care. ICER was €5.32 per additional night spent in independent housing. In sensitivity analyses, HF was less costly and more effective in 28% of iterations.

Conclusions:

HF proves to be cost-effective in homeless people with mental disorders and may assist decision-makers in defining conditions for further implementation of these innovations in Europe.

Key messages:

- Housing First model proves to be cost-effective in homeless people with mental disorders.
- Housing First model was less costly and more effective in 28% of ieration compared to treatment as usual.

Mathematical modeling of medical equipment needs for public health purposes

Marija Jevtic

J Gajic[1], I Gengeljacki[2], N Tesic[2], N Misanovic[2], M Zunji[2], N Bjelica[2], S Cocic[2], M Jevtic[1,3], Z Luzanin[4], D Jakovetic[4]
[1]Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia
[2]Faculty of Sciences, University of Novi Sad, Novi Sad, Serbia
[3]Institute of Public Health of Vojvodina, Novi Sad, Serbia

[4]Department of Mathematics and Informatics, Faculty of Sciences, University of Novi Sad, Novi Sad, Serbia
Contact: marija.jevtic@uns.ac.rs

Issue:

A public health challenge facing many developing countries is the lack of medical equipment, such as mammograms and CT scanners, as well as the unequal access to available equipment. In order to rationalize costs and provide patients with more equal access to preventive and diagnostic services, optimized distribution based on actual needs, considering factors such as population structure and private sector capacities is necessary. The suggested optimization was made in cooperation between students of public health, applied mathematics, and information technology.

Description of the problem:

Based on Open data released by the institutions of Republic of Serbia, pertaining to radiological equipment operated by state healthcare facilities over a period of three years (2015, 2016 and 2017) and projected population, by sex, age, and region, a mathematical model has been made, aimed at optimizing equipment distribution across the 4 regions. With the goal of finding an adequate model, region and year specific data were used for calculating the Gini coefficient. Multiple alternatives were tested over a period of a few months, with the results displayed graphically, using a web application presenting the equipment distribution.

Results:

In maximizing the territory covered, the availability of the equipment to the patients was increased, and with it, the equipment's utility. The results indicate savings can be achieved, taking into consideration the capacities of the private sector.

Lessons:

An adequate mathematical model can contribute to a better distribution of equipment, as well as cost saving. Taking into consideration that inadequate funding is one of the major challenges faced by state healthcare services worldwide, with appropriate data, the model would find use in other countries as well.

Key messages:

- Open medical data opens up new space for action by the interested parties.
- Inter-professional cooperation holds great potential in solving public health problems.

Economic burden of HIV disease from 2012 to 2017 based on the French national claim database (SNDS)

Laurence Pestel

LP Pestel[1], PC Constantinou[1], MN Nicolas[1], SR Rivière[1], AR Rachas[1], CGM Gastaldi-Ménager[1]
[1]Department of Studies on Patients and Diseases, French National Health Insurance (CNAM), Paris, France
Contact: laurence.pestel@assurance-maladie.fr

Background:

The aim of this study was to assess the economic burden of HIV disease in France, by analyzing structure and trends of expenditure between 2012 and 2017.

Methods:

We identified people with HIV disease among beneficiaries of the health insurance general scheme (covering more than 57 million people, 87% of the French population), applying algorithms combining inpatient and outpatient diagnoses and claims for specific drug treatments or laboratory examinations. The individuals' expenditure (26 different items) reimbursed for hospitalizations, ambulatory care and cash payments were included. A top-down method was used to attribute expenditure to HIV disease based on the average expenditure calculated for individuals with only HIV disease. To analyze trends, we applied the same methodology from 2012 through 2017.

Results:

In 2017, HIV disease was identified for 131 800 individuals (0.2% of the population) and expenditure attributed to HIV disease corresponded to €1.3 billion (1% of the 140.1 billion reimbursed by the general insurance scheme). Drug treatment accounted for 85% of total expenditure reimbursed (1.2 billion). Between 2012 and 2017, the number of HIV patients identified increased steadily (+16,800 patients with an annual growth rate of 2.8%) and expenditure attributed to HIV disease increased by €8 billion. However, annual expenditure growth was variable, as a result of instability in the average annual cost per patient, ranging from 9,700€to 11,100€per year per patient. This reflects changes in practice and drug prices.

Conclusions:

The detailed analysis of expenditures attributed to HIV disease showed that drug treatments account for the large majority of total reimbursements. Annual variation in total expenditure could therefore reflect evolution in prescription practices, such as the extension of treatment indications; or in drug prices, with the availability of combined treatments.

Key messages:

- Drug treatments account for the large majority of total reimbursements among HIV patients.
- Variation in total expenditure attributed to HIV disease is mainly driven by prescription practices and drug prices.

7.S. Infectious diseases control

The recent Italian vaccination law and the role of Local Health Authorities: the case of LHA Roma 1

Emanuela Maria Frisicale

EM Frisicale[1,2], MT Miceli[1], MR Romagnuolo[1], R Agostinacchio[1], F De Angelis[1], F Gangere[1], B Giudiceandrea[1], AM Rombolà[1], A Spadea[1], M Goletti[1]
[1]ASL Roma 1, Rome, Italy
[2]Department of Public Health, Università Cattolica del Sacro Cuore, Rome, Italy
Contact: emanuela.frisicale@aslroma1.it

Issue/problem:

The increase of vaccine hesitancy is leading to decrease vaccination coverage. In Italy, a new vaccination law was approved in July 2017 to contrast the spread of preventable infections. 10 vaccines became mandatory for children and unaccompanied foreign minors aged 0-16 and provided for free according to the national immunization schedule for each birth cohort. Being vaccinated is now required to attend schools and kindergartens even if a ban for students aged 0-6 or a fine for the other are previewed.

Description of the problem:

According to the law, in Lazio Region, a web platform was realized in May 2018 in order to permit schools to update the list of their pupils. Medical doctors from LHAs had to evaluate continuously the updated lists, verifying the vaccination status of each student in order to approve their enrolment at schools or to recall parents providing counseling about vaccination.

Results:

From August 2018 to March 2019 schools settled in the area of LHA Roma 1 registered 121.687 pupils (among those 105.720 pupils were also resident in the area of LHA Roma 1). After a preliminary check within data already present in the regional vaccination registry, around 30 healthcare operators, from the 6 healthcare districts of LHA Roma 1, were widely involved in order to evaluate pupils' vaccination status. The number of evaluations decreases in the same period from 19.634 to 4921, but 4908 out of these 4921 were pupils not found in the regional vaccination registry, probably for errors in the registration of personal data such as the fiscal code. Some students' families received vaccination counseling.

Lessons:

The web platform realization was an innovative way to monitor vaccination status: it facilitates a further collaboration among schools and LHAs in order to guarantee health in community and to increase awareness about vaccinations and their benefits. A great involvement of schools and healthcare operators was observed.

Key messages:

- Although some problems such as pupils not found in the regional vaccination registry persist, the way of working in a collaborative way addressing community troubles is clearly traced.
- Technology and information systems help community services in monitoring and improving health outcomes. Their use has to be improved and promoted.

Azienda Sanitaria Locale Roma 4: the external evaluation as strategy to improve vaccination services

Clara Fusillo

C Fusillo[1], *MT Sinopoli*[1], *L Morucci*[2], *C Marchetti*[1], *G Quintavalle*[1]
[1]ASL Roma 4, Civitavecchia, Italy
[2]Università degli Studi Tor Vergata, Rome, Italy
Contact: clara.fusillo@aslroma4.it

Issue:

Azienda Sanitaria Locale (ASL) Roma 4 is one of the ten local healthcare companies of Lazio Region. Vaccination Service (VS), organized in 15 ambulatories, is managed by dedicated and trained staff and this organization has led to high vaccination coverage over the years. In 2017, the National Immunization Plan and the new law on mandatory vaccination required a reshaping of VS. The Health Management of ASL Roma 4 has requested an external evaluation of the VS to a private company (PC) with the aim to highlight weaknesses and strengths.

Description of the problem:

The PC, through inspections and questionnaires addressed to personnel, analysed four features: amplitude of the access to the ambulatory; management of the access; communication; tools. The analysis focused specifically on vaccination for people under 18 years old.

Results:

The PC underlined these weaknesses: massive free access; strong influx of users from other adjacent ASL; computerized vaccination registry not available online; absence of a centralized booking and information request system; lack of targeted use of social networks. Best practices of the VS are: vaccination stocks centrally managed; preventive interview for travellers; structured procedures shared throughout the territory; focused vaccination campaigns; information material sent to the families of the new born; online portal available to users to view their personal data and download vaccination certificates; vaccination counselling; openings dedicated to specific user categories.

Lessons:

The PC suggested these solutions: division of ambulatory opening into free access and booking/active call; online computerized registry; unique call center constitution; creation of official social network pages. ASL Roma 4 activated the unique call center and taken corrective actions for the other weaknesses.

Key messages:

- Best practices can be used in other healthcare setting and the periodically external evaluations can improve the vaccination service.
- Continuously monitoring the activities improves the quality of the vaccination service.

A systematic review of factors influencing pregnant women's future vaccination choices

Annalisa Rosso

A Rosso[1,2], *A Massimi*[1], *G Adamo*[1], *V Baccolini*[1], *E Pitini*[1], *MR Vacchio*[1], *C Marzuillo*[1], *C De Vito*[1], *P Villari*[1]
[1]Department of Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy
[2]Azienda Sanitaria Locale Roma 2, Rome, Italy
Contact: annalisa.rosso@uniroma1.it

Background:

Over the last years, vaccine hesitancy has been increasing globally, leading to a decrease in vaccination coverage in several Countries, mostly in Europe. Several systematic reviews were conducted to assess the determinants of hesitancy and of vaccination choices, but none of them focused on pregnant women, which would represent an ideal population to promote correct information on vaccines.

Methods:

We conducted a systematic review of studies assessing knowledge and attitudes on paediatric vaccinations, vaccination choices and their determinants among pregnant women. We searched Medline, Scopus and Web of Science, adapting search terms to the different databases, following PRISMA Statement criteria. No time limits were set.

Results:

A total of 5,309 records were retrieved. After duplicates removal and title/abstract selection, 15 full texts were included in the narrative synthesis. Most studies (14/15) were quantitative surveys, 2 focused only on specific vaccines (rotavirus and HPV), 4 studies were conducted in European countries (Germany and Italy). The main factors associated with vaccine hesitancy or refusal were the fear of side effects, in particular for the most recent vaccines, the perception of a greater importance of natural immunity and a low perception of utility of vaccines, the lack of trust in health professionals, having obtained information on vaccines not from a doctor, primiparity and a low level of education (for these two last factors, with inconsistent results between studies).

Conclusions:

Available evidence shows that the perceived risks and importance of vaccinations and the information received during pregnancy can influence vaccination choices of future mothers, and that the determinants of hesitancy may vary in different contexts. Pregnant women represent a key population for the implementation of interventions aimed at increasing knowledge and acceptance of vaccinations, which should be based on an analysis of the specific context.

Key messages:

- The perceived risks and importance of vaccinations and the information received during pregnancy can influence vaccination choices of future mothers.
- Interventions aimed at increasing knowledge and acceptance of vaccinations should be based on an analysis of the specific context.

Are midwives ready to fight vaccine hesitancy? First results from an Italian cross-sectional study

Azzurra Massimi

A Massimi[1], *A Rosso*[1], *C De Vito*[1], *C Marzuillo*[1], *V Baccolini*[1], *E Pitini*[1], *D Barbato*[1], *P Villari*[1]
[1]Department of Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy
Contact: azzurra.massimi@uniroma1.it

Background:

Pregnancy is widely recognized as a 'teachable moment' since attitudes and beliefs about childhood vaccines are not completely structured. Among healthcare workers (HCWs), midwives play a pivotal role in the maternal care pathway and should have a key role also in promoting opportunities of discussion and correct information about vaccinations.

Methods:

We conducted a cross-sectional survey to assess knowledge and attitudes of a sample of Italian midwives towards vaccinations. A questionnaire was designed ad hoc and sent electronically to midwives members of the professional register of Rome.

Results:

Preliminary results on data collected from 140 midwives (mean age 37.32, DS ± 11.61; mean years on the job: 11.94 DS ± 12.78) who completed the survey showed a heterogeneous level of knowledge: only 50% of the sample indicated the correct threshold of vaccination coverage for herd immunity, while safety of multiple shots and of the additives contained in vaccines was reported by 61% and 31% of respondents, respectively. Only 41% of midwives had identified the pertussis vaccine as one of the vaccinations recommended during pregnancy. Attitudes were generally positive: 84% of respondents recognized recommended vaccines as effective and 86% as one of the safest health interventions. However, vaccinations against MMR and Varicella were perceived as useful by 86% and 71% of the midwives, while 89% and 77%, respectively, would recommend them to parents (compared to 96% in case of hexavalent). Globally, 79% of respondents would agree with the introduction of mandatory vaccinations for HCWs in maternity wards.

Conclusions:

Midwives show some gaps in the knowledge on vaccinations. The final results of this study will be used to build specific and tailored training programs directed to midwives involved in pregnancy management. This may help them to transfer the correct vaccination information for the empowerment and the growth of vaccine literacy.

Key messages:

- Pregnancy is a strategic teachable moment to influence attitudes regarding childhood vaccinations and healthcare professionals must be trained to be the vehicle of the most accurate information.
- Specific under- and post-graduate training courses on vaccinations directed to midwives are strongly needed to ensure good level of knowledge on this topic.

Healthcare Workers' attitudes towards mandatory influenza vaccination: a systematic review

Michele Corezzi

M Corezzi[1], MR Gualano[1], G Voglino[1], E Olivero[1], P Rossello[1], F Bert[1], R Siliquini[1]

[1]Department of Public Health Sciences, Università degli Studi di Torino, Torino, Italy

Contact: michele.corezzi@unito.it

Background:

Influenza affects approximately between 5 to 10% of general population every year, leading to 3 to 5 million cases of severe illness, and about 290 000 to 650 000 respiratory deaths. Healthcare Workers (HCWs) play a crucial role in spreading the infection to patients. Although the strong recommendations provided, influenza vaccination coverage rates among HCWs are globally well below the coverage target set by WHO. The aim of this study is to assess attitudes towards mandatory influenza vaccination programs among HCWs, in order to make a quantitative synthesis of the phenomenon.

Methods:

The present study systematically reviewed published cross-sectional studies investigating attitudes towards compulsory influenza vaccination in Healthcare Workers. PubMed and Scopus scientific databases were searched and 4,198 results were returned. Of these, 23 met the inclusion criteria for the review and 13 were eligible for the meta-analyses. PRISMA statements were followed.

Results:

Thirteen studies were conducted in North America, 4 were conducted in Europe, 3 in Asia, 2 were performed in Australia and one study collected data both from Europe and Asia. According to the assessed studies, the percentage of agreement ranged from 44% to 95% for different compulsory vaccination programs. A combined prevalence of 59.8% (95%CI 50.1-68.8) was found in the meta-analysis. Having been vaccinated against influenza in the previous year increases the likelihood (OR 4.1; 95%CI 2.8-6.1) of being in favour of mandatory vaccination policies.

Conclusions:

Compulsory influenza vaccination programs are generally accepted by the majority of health professionals, especially by those who have already been vaccinated previously. These results could be important to improve European vaccination strategies, in order to increase influenza vaccination rates among Healthcare Workers.

Key messages:

- Mandatory influenza vaccination programs are accepted by the majority of Healthcare Workers.
- Having been previously vaccinated against influenza increases the likelihood of being in favor of a mandatory vaccination policy.

Impact of hepatitis B vaccine in Tunisia 20 years after its introduction

Aicha Lahchaichi

A Lahchaichi[1], M Ben Hadj[1], H Bouguerra[1], K Talmoudi[1], A Bahrini[1], O Bahri[3], H Letaief[1], O Hazgui[2], N Hannachi[2], N Ben Alaya Bouafif[1]

[1]National Observatory of New and Emerging Diseases, Tunis, Tunisia

[2]Laboratory of Microbiology, Farhat Hachad Hospital, Sousse, Tunisia

[3]Laboratory of Microbiology and Virology, Aziza Othmana Hospital, Tunis, Tunisia

Contact: aicha.hechaichi@gmail.com

Introduction:

Vaccination against hepatitis B represents the most effective preventive measure to reduce the global impact of this infection. In Tunisia hepatitis B vaccination was introduced for health professionals in 1992 and for the general population in 1995. The objectives of this study were to evaluate the impact of vaccination twenty years after its introduction.

Methods:

It was a descriptive study of data provided by the national survey of prevalence of Hepatitis B in Tunisia, which was a household-based study conducted in 2015. Blood samples sent to the reference laboratory to test markers of hepatitis B virus infection. The Vaccine effectiveness rate was calculated using the following formula: VE = 1 - Odds-ratio (OR), where OR = ratio of odds of being vaccinated among subjects with positive HBsAg test results to the odds of being vaccinated among subjects with negative HBsAg test results.

Results:

Approximately a quarter of our population reported having been vaccinated against HBV, a coverage rate of 26.9%. Among subjects above 20 years of age, this rate was 85.3%. Besides, 83.7% of vaccinated subjects had received the three required doses of the HBV vaccine. Analysis of vaccination status by great regions of the country showed that the vaccination coverage rate was higher in the southern region. Regarding HBsAg prevalence, the rate was significantly higher among unvaccinated subjects 0.3% vs 2.2% in those vaccinated (OR = 0.11 [0.07-0.18]). We found that among vaccinated subjects, the serologic response rate at vaccination was only 63.2% which represented 16.2% of the total population. The vaccine effectiveness indicated that vaccination reduced by 88.6% the risk of HBV infection.

Conclusions:

These results demonstrate that vaccination against hepatitis B introduced in the national immunization schedule since 1995 has reduced the infection although the vaccination coverage rate remains below 90%.

Key messages:

- Importance of vaccination that reduced by 88.6% the risk of HBV infection.
- More effort required to raise awareness about vaccination against HBV.

Vaccine Prevention of Paediatric Chronic Lung Disease: Targeting Haemophilus

Magdalene Parkes

M Parkes[1,2,3], *KA O Grady*[2]
[1]Department of Medicine, Logan Hospital, Brisbane, Australia
[2]Centre for Children's Health Research, Institute of Health, Queensland University of Technology, Brisbane, Australia
[3]School of Public Health, University of Sydney, Sydney, Australia
Contact: magdalene.parkes@gmail.com

Background:

Chronic Suppurative Lung Disease (CSLD) is an emerging term encompassing a spectrum of chronic childhood respiratory disease. Characterised by early and severe infections and recurrent exacerbations, it is associated with progressive deterioration in lung function and quality of life. CSLD is highly unequally distributed and largely preventable, and is a major contributor to the global burden of chronic paediatric respiratory disease. Relatively few pathogens comprise the main culprit organisms identified in the aetiology of CSLD, over which Non-Typeable Haemophilus influenzae (NTHi) predominates.

Methods:

We review developments that establish the role of NTHi in disease progression, focusing on high-risk population subgroups with an established CSLD burden. We consider current studies examining the role of prenatal NTHi and pneumococcal vaccination in preventing CSLD through reducing infections in high-risk populations, and discuss current directions in future research, including the need for precise identification of the pulmonary microbiome in CSLD.

Results:

Early, repeated NTHi infections are clearly implicated in the aetiology of CLSD. Early results of current studies indicate NTHi vaccination may reduce the frequency of causal infections in high-risk groups. Clinical and immunological data show vaccination also reduces frequency of exacerbations and antibiotic usage in CSLD.

Conclusions:

We provide the first clinical and immunological data for H. influenzae vaccination in children with CSLD. Targeted vaccination strategies may prevent CSLD establishment, slow progression, and potentially reduce morbidity, healthcare presentations and antibiotic consumption. This implicates vaccination as a potential aid in both antimicrobial stewardship and prevention of chronic disease. In the face of threats posed to health systems by antimicrobial resistance and the growing burden of chronic disease, vaccination is again emerging as a uniquely powerful public health tool.

Key messages:

- Hi vaccination can reduce infective exacerbations and antibiotic use in children with CSL.
- Vaccines may have a role in preventing chronic disease progression and reducing antibiotic reliance.

Serologic antibody response to quadrivalent influenza vaccination in Polish elderly patients

Paulina Dubiel

P Dubiel[1], *M Ganczak*[1], *M Drozd-Dąbrowska*[1], *E Hallmann-Szelińska*[2], *K Szymański*[2], *LB Brydak*[2]
[1]Department of Epidemiology and Management, Pomeranian Medical University, Szczecin, Poland
[2]The Department of Influenza Research, National Influenza Center, The National Institute of Public Health – The National Institute of Hygiene, Warsaw, Poland
Contact: paulina.dubiel@pum.edu.pl

Background:

The effectiveness of immunization with subunit inactivated quadrivalent influenza vaccine (QIV) in the elderly has not been sufficiently estimated. The study objective was to evaluate QIV-induced antibody response and influencing determinants in Polish elderly patients.

Methods:

Consecutive patients $\geq$55 years old attending the Primary Care Clinic in Gryfino, Poland, received QIV (A/Michigan/45/2015 [A/H1N1/pdm09], A/Singapore/INFIMH-16-0019/2016 [A/H3N2/], B/Colorado/06/2017 [Victoria lineage], B/Phuket/3073/2013 [Yamagata lineage]) between October-December 2018. Hemagglutination-inhibition assays measured antibody response to vaccine strains before/after vaccination. Geometric mean titer (GMT)/titers ratio (GMTR), protection (PR) and response (RR) rates were calculated.

Results:

Among 108 participants (45.4% females; age 55-85, median 67 years) the highest GMTR after vaccination was observed for A/H3N2/(61.5-fold) followed by Victoria lineage (10.3-fold), A/H1N1/pdm09 (8.4-fold) and Yamagata lineage (3.0-fold). Most participants had a post-QIV protection for A/H3N2/ and Yamagata lineage vaccine strains (64.8%, 70.4% respectively); lower PR were observed for Victoria lineage (57.4%) and A/H1N1/pdm09 (41.8%). The RR was high for A/H3N2/ (91.7%) and Victoria lineage (68.5%), however, not satisfactory for A/H1N1/pdm09 and Yamagata lineage (59.3%, 52.8% respectively). Patients who received influenza vaccination in the previous year presented lower response to the both B strains compared to those who did not ($p < 0.0001$ and $p = 0.03$ respectively).

Conclusions:

Although vaccine-induced antibody response in the elderly Polish population was more effective against A/H3N2/and B Victoria, this introductory study supports the use of QIV. Prior season vaccination was associated with lower antibody response to the current vaccination; this was not consistent to vaccine strains. Further research to better investigate QIV effectiveness determinants in the elderly would be of value.

Key messages:

- Subunit inactivated quadrivalent influenza vaccine (QIV) is effective in elderly people and should be used.
- The response to vaccination is not consistent and depends on the strain of influenza virus.

Being Born during a Flu Pandemic as Risk Factors for Development of Schizophrenia

Francisco Guillen Grima

F Guillen Grima[1,2,3], *A Brugos-Larumbe*[1,3,4], *S Guillen-Aguinaga*[1,4], *MA Alvarez-Mon*[5], *V Pereira-Sanchez*[5], *F Ortuño*[5,3], *MJ Al-Rahamneh*[6], *L Onambele*[1,7], *I Aguinaga-Ontoso*[1,2]

[2]Department of Preventive Medicine, Clinica Universidad de Navarra, Pamplona, Spain
[3]Navarra Institute of Health Research, IDISNA, Pamplona, Spain
[4]Primary Health Care, Navarra Health Service, Pamplona, Spain
[5]Departmen of Psychiatry, Clinica Universidad de Navarra, Pamplona, Spain
[6]Global Health Devlopment (GHD), The Eastern Mediterranean Public Health Network (EMPHNET), Amman, Jordan
[7]École des Sciences de la Santé, Université Catholique d'Afrique Centrale, Yaoundé, Cameroon
Contact: f.guillen.grima@gmail.com

Background:

Schizophrenia is a neurodevelopmental disorder of complex etiopathogenesis involving genetic and environmental factors. Mother's exposure to infectious agents during pregnancy has been, implicated in the pathogenesis of schizophrenia. Studies in experimental models support that flu virus can cause embryonic neurodevelopment damage such as that described for embryos that later develop schizophrenia, but epidemiological studies of the association between schizophrenia and gestation in times of a documented flu pandemic) are contradictory.

Methods:

The study is a cross-sectional study within the APNA Study (Navarre primary health care prospective cohort) that included 470942 people over 18 years old in Navarre (Spain). Date of birth, sex, and schizophrenia diagnoses made by psychiatrist on the basis of ICD-10 were extracted. People were classified according if their birth dates occurred within or around periods of flu pandemics in the second half of the 20th century: 1957, 1968 and 1977. The dates for these groups were from January of the year of the pandemic until December of the subsequent year. Logistic regression of adjusted by sex, age, and month of birth was performed. Because the cohort only includes people over 18 years of age, data for patients born during the influenza A subtype H1N1 outbreak of 2009 were not available.

Results:

Males have a higher prevalence of schizophrenia than females (OR = 1.516, 95% CI:
1.388-1.655), Adjusting by gender, month of birth and age, subjects born during (or the year after) years of flu pandemic relative to subjects born in non-pandemic years (OR = 1.335, 95% CI = 1.199-1.486). The latter relationship held for each pandemic studied in isolation of the others, with ORs of 1.476 (95% CI: 1.244-1.750) for the 1957-59 pandemic, 1.261 (95% CI: 1.060-1.493) for the 1968-70 pandemic and 1.280 (95% CI: 1,072- 1,528) for the 1977-78 pandemic.

Conclusions:

Been born during a flu pandemic may increase the risk of developing schizophrenia.

Key messages:

- Exposure to the influenza virus during gestation may increase the risk of schizophrenia.
- Flu Vaccination in pregnant women may reduce the risk of schizophrenia in their children.

Severe outcomes following invasive pneumococcal disease in adults in France

Kostas Danis

K Danis[1], *MC Ploy*[2], *E Varon*[3], *D Levy-Bruhl*[1], *SIIPA group*[2], *J Gaillat*[4]
[1]Department of Infectious Diseases, Santé Publique France, Saint Maurice, France
[2]CHU de Limoges, University of Limoges, Limoges, France
[3]National Centre for Pneumococci, Centre Hospitalier Intercommunal Créteil, Créteil, France
[4]Centre Hospitalier Annecy Genevois, Annecy, France
Contact: costas.danis@santepubliquefrance.fr

Pneumococcal vaccine serotypes and host factors may increase the risk of severe invasive pneumococcal disease (IPD). In France, pneumococcal vaccination in adults is recommended for at-risk groups (immunosuppression or at-risk conditions/ diseases). In 2014-2017, we conducted a study of IPD in adults to identify factors/serotypes associated with disease severity.

We included IPD cases, excluding meningitis, in adults from 25 acute-care sentinel hospitals in six regions. Severe cases were IPD patients either admitted to an ICU or under mechanical ventilation or with severe sepsis or shock. Infectious disease specialists collected clinical/microbiological data on all cases. We calculated adjusted risk ratios (aRR) using binomial regression.

In 2014-2017, 908 cases (median age 71 (range 18-101) years) were diagnosed; 48%(431/908) were severe and 84%(764/908) were at-risk. Compared with non-risk individuals, the risk of severe disease increased from 20% (aRR 1.2; 95%CI 1.0-1.4) in cases with 1-2 chronic diseases to 30% (aHR 1.3; 95%CI 1.0-7.0) in those with >2 chronic diseases. The risk of severe disease was 42% (aRR 1.4; 95%CI 1.2-1.6) higher for PCV13 serotypes compared with non-vaccine serotypes. Among cases infected with PCV13 serotypes, the risk of severe disease did not differ (aRR 0.96; 95%CI 1.2-23) between no-risk or at-risk cases. However, among cases infected with non-vaccine serotypes, the risk increased 49% (aRR 1.5; 95%CI 2.1-22) in at-risk compared with no-risk cases (homogeneity test p = 0.03).

We observed a cumulative effect of concurrent comorbidities on severe IPD outcomes. The risk of severe IPD increased for vaccine serotypes regardless of risk status. However, non-vaccine serotypes increased the risk of severe outcomes only in risk groups, suggesting a different interplay between host factors and the pathogen in vulnerable groups. We recommend enhancing vaccination among risk groups and especially in those most at risk for poor IPD-related outcomes.

Key messages:

- Cumulative effect of concurrent comorbidities on severe invasive pneumococcal disease outcomes.
- Non-vaccine serotypes increase the risk of severe invasive pneumococcal disease outcomes only in vulnerable groups.

Improving access to post-exposure prophylaxis for Lyme disease: a role for community pharmacists

Geneviève Baron

G Baron[1,2,3], *L Pinsonneault*[1,2,3], *A Binet*[2], *C-A Philie*[2], *M Bonapace-Potvin*[2], *S Lio*[2]
[1]Eastern Townships Public Health Department, Sherbrooke, Canada
[2]Faculty of Medicine and Health Sciences, Université de Sherbrooke, Sherbrooke, Canada
[3]University Institute of Primary Care and Social Services, Eastern Townships Health and Social Services Center, Sherbrooke, Canada
Contact: genevieve.baron@usherbrooke.ca

Issue:

Virtually non-existent in Eastern Townships (ET) before 2010, Lyme disease incidence rate reached 52 confirmed cases per 100 000 in some districts in 2018, leading to post-exposure prophylaxis (PEP) recommendation by public health. To improve access to PEP, community pharmacists can now screen and initiate PEP under a collaborative practice agreement (CPA) with the regional Medical Officer of Health. Knowledge, attitudes and practices of pharmacists regarding Lyme disease PEP were surveyed after implementation of this measure.

Description of the problem:

312 community pharmacists practicing in ET were invited, in October 2018, to complete an online survey, based on Godin's integrative model (2012), with questions on professional characteristics, knowledge of CPA, attitudes about PEP, and facilitators and barriers to the use of CPA. Pharmacist's practices were evaluated using 8 clinical vignettes. Vignette-specific and a global score were calculated. Bivariate analyses were done to test the association between global score and knowledge, attitudes, facilitators and barriers.

Results:

Response rate was 13.8%. Most pharmacists knew (97.4%) and were in favor (93.1%) of the CPA, and believed it was effective to prevent Lyme disease (96.4%). The main barriers reported to using the CPA were related to the assessment of PEP criteria. With regards to practice, pharmacists answered correctly for clients presenting all criteria for PEP (80.6%), aged < 8 y.o. (51.6%), who had their tick removed for >72 hrs (67.7%), already presenting with symptoms (32.3%) or who had exposure in a non-endemic area (38.7%). Finally, none of the variables studied were associated with the global score.

Lessons:

This measure has now been expanded in other endemic regions in Quebec and a provincial CPA is under development. These results will help guide the development of the provincial CPA, specifically to better consider and to provide guidance regarding PEP contraindications.

Key messages:

- Pharmacist-initiated PEP is an innovative approach to increase timely population access to an essential preventive measure in the fight against Lyme disease in endemic districts.
- Additional guidance is required for pharmacists with regards to assessment of PEP criteria in future CPAs.

Advancement of hepatic fibrosis among general women with/without NAFLD

Rie Ibusuki

R Ibusuki[1], *I Shimoshikiryo*[1], *K Shimatani*[2], *D Nishimoto*[1], *S Maenohara*[3], *T Takezaki*[1]
[1]Department of International Island and Community Medicine, Graduate School of Medical and Dental Sciences Kagoshima University, Kagoshima, Japan
[2]Department of Nursing, Tokyo Healthcare University Postgraduate School of Nursing, Tokyo, Japan
[3]Kagoshima Kouseiren Medical Health Care Cente, Kagoshima, Japan
Contact: iburie@m2.kufm.kagoshima-u.ac.jp

Background:

Nonalcoholic fatty liver disease (NAFLD) is increasing, being prevalent at 30% of the general population worldwide. A part of NAFLD develops nonalcoholic steatohepatitis (NASH), liver cirrhosis and hepatocellular carcinoma. Hepatic fibrosis plays an important role in their pathogenesis. However, it is unclear how hepatic fibrosis is observed and advanced in NAFLD among general population. To investigate the hepatic fibrosis among general population, we prospectively observed hepatic fibrosis using serum markers.

Methods:

The subjects were 228 women who participated as a part of the Japan Multi-Institutional Collaborative Cohort (J-MICC) study in Kagoshima, Japan, and were followed from 2005 to 2014. NAFLD was defined as fatty liver by abdominal ultrasonography; consuming ethanol $<$ 20 g/day; and being none hepatitis B and C carriers. NAFLD were confirmed after two-time consecutive examination, because its disappearance is ambiguous in some cases. Hepatic fibrosis was evaluated using serum M2BPGi and Type IV collagen 7s. The comparison of their changed values between groups was done using the ANOVA adjusted for age. The association between their change and related factors was done using general linear regression model.

Results:

The prevalence of NAFLD was 31.6% at baseline. In the 5-year observation, the NAFLD + => NAFLD + (++) group was 23.7%; − +, 2.6%; + −, 7.9%; and - - (control), 65.8%. The values of M2BPGi and Type IV collagen 7s were higher in ++, -+, +- groups than controls at baseline. The change of M2BPGi values was observed in all groups, including controls, and the changed values were higher in ++ and -+ groups. Higher creatinine levels were positively associated with change of M2BPGi values. In contrast, the change of Type IV collagen 7s was not apparent.

Conclusions:

This study suggested hepatic fibrosis was advanced with age among general women without NAFLD, and the presence of NAFLD enhanced hepatic fibrosis more.

Key messages:

- Hepatic fibrosis may be slightly developing with age among general population, and will be enhanced with fatty liver.
- It is important to prevent fatty liver development to control risk factors, such as obesity and metabolic syndrome, to reduce the risk of NASH, liver cirrhosis and hepatocellular carcinoma.

8.R. Addiction and other matters

Treatment of the opioid use disorder in the primary health care in The City of Zagreb

Danijela Stimac

M Margreitner[1], *D Stimac Grbic*[2,3], *O Santini Manzin*[1], *V Bralic Lang*[4]
[1]Health Centre East, Family Practice, Zagreb, Croatia
[2]Dešpartment for Mental Health, Croatian Institute of Public Health, Zagreb, Croatia
[3]School of Medicine, University of Zagreb, Zagreb, Croatia
[4]Private General Practicioners Office, Family Practice, Zagreb, Croatia
Contact: danijela.stimac@hzjz.hr

Issue/problem:

Management of patients with opioid use disorder commonly includes opioid agonist therapy as a part of an integrated treatment plan. These interventions are associated with proven benefits to the individual and society. Treatment choices in opioid use disorder pharmacotherapy should be based on the needs of the individual and characteristics of medications.

Description of the problem:

The aim was to present the use of pharmacotherapy in the treatment of opioid use disorder in family medicine practice in Zagreb. We collected data from 30 family physician practices, on patients treated for opioid use disorder. We analyzed the epidemiological characteristics of the patient, the diagnosis according to ICD X rev., as well as the frequency of the medication use and the duration of the treatment.

Results:

Data about 100 patients treated for opioid use disorder were obtained, (88% men and 12% women). The average age of the patients was 37.9 years. From all patients, 31% had dg. F.60, 22% had dg. F19, 15% had dg. F32, 3% had dg. F29. 19% of patients was HCV positive. 62%of patients were treated with buprenorphine and 38% with methadone. In 5% of patients buprenorphine was only medication in therapy. 53% of patients with buprenorphine use diazepam, 30% use buprenorphine with antidepressant, and 12% use diazepam and antidepressant with buprenorphine. All patients who are on methadone therapy are using some other medication in therapy. Methadone is commonly prescribed in combination with diazepam and antidepressant (55%). The following combination is methadone and diazepam (34%), a combination of methadone, antipsychotics and pregabalin (7%) and a combination of methadone, antidepressants and antipsychotics (4%). The average duration of treatment for opiate addicts is 11.9 years.

Lessons:

Patients who use buprenorphine in the treatment of opioid use disorder have less need for additional medication in therapy than patients who use methadone.

Key messages:

- Patients who use buprenorphine in the treatment of opioid use disorder have less need for additional medication in therapy than patients who use methadone.
- Treatment choices in opioid use disorder pharmacotherapy should be based on the needs of the individual and characteristics of medications.

Risk factors for hazardous drinking in university students from South Africa and Belgium

Guido Van Hal

G Van Hal[1], *Y Larivière*[1], *Y Inaç*[1], *M Hoque*[2]
[1]Social Epidemiology and Health Policy, University of Antwerp, Antwerp, Belgium
[2]Graduate School of Business and Leadership, University of KwaZulu-Natal, Durban, South Africa
Contact: guido.vanhal@uantwerp.be

Background:

Previous studies have associated certain risk factors with hazardous drinking in students. However, big cultural and geographical differences exist regarding alcohol use. In this study, we compare the alcohol use and hazardous drinking in Belgian (BE) and South African (SA) university students.

Methods:

An online survey assessing alcohol use among university students in South Africa (University of KwaZulu-Natal) and Belgium (University of Antwerp) was conducted, using the shortened version of the Alcohol Use Disorder Identification Test (AUDIT-C). For male students a cut-off point of 5 was used for hazardous drinking and for female students a score of 4. In total, 499 students were included in the study (250 BE and 249 SA students). A comparative analysis between both universities was performed for men and women separately with a Pearson chi-square test or Mann-Whitney U test. Furthermore, the association between hazardous drinking and several exposure variables was explored using multivariable logistic regression analysis.

Results:

A significant higher amount of male (94.8%) as well as female (92.4%) BE students drank alcohol in the last year compared to the male (66.2%) and female (67.8%) SA students ($p < 0.001$). Additionally, a significant higher amount of BE students were hazardous drinkers, compared to the SA students ($p < 0.001$). Multivariate analysis showed that male BE students were approximately five times more likely to be hazardous drinkers than male SA students (OR = 5.057, 95% CI 1.378-18.556; p = 0.015). Female BE students were over twice more likely to be hazardous drinkers than female SA students (OR = 2.371, 95% CI 0.846-6.644; p = 0.099).

Conclusions:

BE students drink significantly more alcohol and a significant higher proportion of BE students were hazardous drinkers compared to SA students. Qualitative research in both groups has been conducted to get more insight into the reasons of these differences and will also be presented at the Conference.

Key messages:

- When studying alcohol use (disorders) in university students, it is of utmost importance to take into account the socio-cultural context.
- After finding quantitatively assessed differences in alcohol use (disorder) across different socio-cultural settings, it is evenly important to find out about the reasons why.

The role of unjust treatment for experienced unmet need for health care among Finnish Roma

Hannamaria Kuusio

H Kuusio[1], *R Lämsä*[1], *M Laalo*[1], *A Castaneda*[1]
[1]National Institute for Health and Welfare, Helsinki, Finland
Contact: hannamaria.kuusio@thl.fi

Background:

Finland is currently undergoing a major reform of social and health care, one aim of which, is to reduce inequalities between different population groups in access to care. Previous studies showed that Finnish Roma minority are more likely to experience unjust treatment in health services and other public services in comparison to other minorities in Finland. Unjust treatment may influence health behaviors, including the use of health services, by decreasing trust towards health professionals as well as decreasing social, emotional, and physical resources. This study examined the association between experienced unjust treatment in public services and self-assessed unmet need for health care among Roma in Finland.

Methods:

We used data from the Roma health and wellbeing study (Roosa), conducted in Finland (2017-2018). The data was collected by the snowball method in different areas of Finland including a health examination and a structured interview. It covers 365 adults, and of those 223 (61.1%) were women. The outcome measure for unmet health care need was based on the question: "Do you feel that you have adequately received primary care services during the past 12 months?" Logistic regression was used to test the association between unjust treatment and unmet need for health care. Potential confounders were gender, age, marital status, education, employment and self-estimated health.

Results:

The prevalence of unmet need for health care was 37.8 percent among men and 43.7 percent among women. Those who experienced unjust treatment in public services had higher odds (OR = 6.23; $p < 0{,}001$) for unmet need for health care than those who felt treated just. This association remained after adjustments for the confounders.

Conclusions:

Over every third of the Finnish Roma experienced unmet need for health care. Unjust treatment seems to be a significant risk factor in access to care among Finnish Roma and its role needs further studies.

Key messages:

- Unjust treatment in public services is an indirect indicator of systematic and/or institutional discrimination.
- It is important to study the extent, nature and consequences of unjust treatment and discrimination to allow vulnerable groups to be taken into account better when renewing health services.

Frailty as predictor for all-cause and cause-specific mortality: 11-year follow-up cohort study

Thomas Dorner

TE Dorner[1], *I Grabovac*[1], *C Mogg*[2], *M Oberndorfer*[1], *S Haider*[1]
[1]Department for Social and Preventive Medicine, Centre for Public Health, Medical University Vienna, Vienna, Austria
[2]Department of Sport Science, University Vienna, Vienna, Austria
Contact: thomas.dorner@meduniwien.ac.at

Background:

Frailty is a geriatric syndrome characterised by sarcopenia, malnutrition, and chronic inflammation that leads to adverse health outcomes including dependency, low quality of life, and higher risk for morbidity and mortality. It was the aim of this study to examine the relationship between frailty status and risk of all-cause and cause-specific mortality.

Methods:

The study is based on data from the Survey on Health, Aging and Retirement in Europe (SHARE) including 11 European countries with an 11-year follow up. 24,634 participants with a mean age of 64.2 (9.8) 53.6% female, were analysed. Frailty status was calculated using the SHARE- Frailty Instrument, categorizing the participants as robust, pre-frail, and frail. Cox Proportional Hazard models were used to estimate the risk of all-cause and cause-specific (stroke, heart attack, other cardiovascular disease, cancer, respiratory illness, infectious, digestive and other) mortality in frail and pre-frail subjects compared to robust persons.

Results:

14.7% and 6.9% were found to be pre-frail or frail at the baseline. During the follow-up, we observed both pre-frailty and frailty being associated with a higher risk of all-cause and cause-specific mortality in the unadjusted model. After adjusting for sex, age, education level, body mass index, smoking, alcohol consumption and a number of comorbidities, frailty was associated with a higher risk of all-cause mortality [HR 1.56 (95% CI 1.37-1.78)], and mortality due to other cardiovascular diseases [HR 1.88 (95% CI 1.27-2.76)], cancer [HR 1.47 (95% CI 1.14-1.90)], and respiratory disease HR [1.82 (95% CI 1.10-3.01)]. Furthermore, pre-frailty was associated with a higher risk of all-cause mortality [HR 1.27 (95% CI 1.14-1.42)] and other cardiovascular disease mortality [HR 1.70 (95% CI 1.22-2.35)].

Conclusions:

Our study showed that baseline pre-frailty and frailty are associated with increased all-cause and cause-specific mortality over an 11-year follow up.

Key messages:

- Frailty but also pre-frailty leads to a higher mortality, even when adjusted for morbidity, lifestyle factors, and socio-demographic factors.
- More effort is needed to prevent, detect, and treat frailty and pre-frailty, both, on individual and on community level.

Potential predictors of unmet health needs among the elderly: a population-based study in Serbia

Milena Šantrić Milićević

M Šantrić Milićević[1], *M Kostadinović*[2], *D Nikolić*[1,3], *J Todorovic*[1], *Z Terzic-Supic*[1]
[1]Faculty of Medicine University of Belgrade, Institute of Social Medicine, Belgrade, Serbia
[2]Clinical Centre of Serbia, Belgrade, Serbia
[3]Physical Medicine and Rehabilitation Department, University Children's Hospital, Belgrade, Serbia
Contact: milena.santric-milicevic@med.bg.ac.rs

Background:

This study assessed the prevalence of unmet health needs of the elderly and the associated factors regarding socioeconomic, health and functional status.

Methods:

A secondary analysis of the 2013 National Health Survey data was conducted on a representative sample of 3540 persons aged sixty-five and older (the lowest response rate was 99.7%). Participants characteristics such as socioeconomic status, health self-perception, diagnosed chronic disease, physical functional limitations, performing essential daily activities in the home and daily personal care were explored with logistic regression analysis (Odds Ratio - OR and 95% Confidence Interval) in relation to five aspects of unmet health needs.

Results:

15.8% participants had unmet health needs due to the long waiting times, 16.1%, had unmet needs for medical care, 17.7% for dental care, 15.2% for drugs prescription and 96.9% participants for mental health care. Common predictors exist for medical, dental drug prescription and due to long waiting times unmet needs including older age years, middle education, rural residence, lower wealth index, single persons, with average or bad self-perceived health, chronic disease and difficult daily performance of personal care and of home activities. Unmet mental health needs by 61% less likely had participants with average wealth index, while a greater likelihood had participants with average and bad self-perceived health by 3.7 times and 8.4 times ($p = 0.035$, $p = 0.001$) respectively, by 6.2 times those with difficulties ($p < 0.001$) and by 5.9 times unable ($p = 0.045$) to perform daily activities of personal care and by 1.7 times those with difficulties ($p = 0.037$) to perform home activities.

Conclusions:

Unmet health needs reported less than 20% of the elderly but almost all have unmet mental health needs. Unmet health needs are associated with negative health outcomes, age, low education level, single persons, rural settings, poorer households, and limited daily activities.

Key messages:

- Unmet mental health needs of the elderly are an extremely important problem for the health system and healthy ageing in Serbia.
- A strong association of unmet health needs of old, low educated elderly without partners, from rural settings and poor households with health and functional outcomes, requires responsive policies.

Changes in work stress among doctors in Norway from 2010 to 2019: a study based on repeated surveys

Judith Rosta

J Rosta[1], *OG Aasland*[1], *K Isaksson Rø*[1]
[1]Institute for Studies of the Medical Profession (LEFO), Oslo, Norway
Contact: judith.rosta@legeforeningen.no

Background:

Changes in the organization of health care can influence the doctorsˋ working conditions, which may in turn impact on doctorsˋ perception of work stress. Since high levels of work stress can affect both the doctors' own health and the quality of patient care, it is of importance for public health. We studied changes in work stress among Norwegian doctors from 2010 to 2018-19, and the associations of high work stress with job positions, self-rated health and sickness absence in 2018-19.

Methods:

The study populations consisted of representative samples of 1,500 to 2,200 doctors working as hospital doctors, general practitioners (GPs), private practice specialists and doctors in academia. Data were drawn from nationwide repeated postal surveys in 2010, 2016 and 2018-19 in Norway. Response rates were between 67%-73%. The main outcome measure was perception of work stress as measured by the validated short form of the Effort-Reward Imbalance Questionnaire (ERI). Linear mixed models, proportions with 95% confidence intervals and logistic regression model were used in the analyses.

Results:

From 2010 to 2018-19, the scores on the effort items (time pressure, responsibility, demands) increased significantly and the scores on the reward items (recognition, job stability, promotion prospects, prestige) decreased significantly for GPs, but remained stable for doctors in other positions. The proportion of doctors with high levels of work stress increased significantly for GPs. In 2018-19, high levels of work stress were associated with being a GP as compared with other job positions, younger age groups, average or poor health vs. very good or good health, but not with sickness absence or gender.

Conclusions:

During a nine-year-period, work stress increased significantly for GPs, but remained stable for other job positions. This may be partly due to several health care reforms. Less work stress may improve both the doctorsˋ own health and the quality of health care.

Key messages:

- From 2010 to 2018-19 in Norway, the proportion of GPs with high levels of work stress increased, while it remained stable for doctors in other job positions.
- This study supports previous findings on the association between high levels of work stress and health.

Midwifery matters: resilience and subjective wellbeing of midwives

Niccolò Vonci

D Caiazzo[1], *L Kundisowa*[2], *G Bocci*[3], *N Vonci*[2], *L Alaimo*[1], *S Ardis*[3], *N Nante*[4]
[1]Degree Course in Obstetrics, University of Siena, Siena, Italy
[2]Post Graduate School of Public Health, University of Siena, Siena, Italy
[3]Italian Society of Promotion of Health, Siena, Italy
[4]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
Contact: nicco.vonci@libero.it

Introduction:

Resilience is the ability to resist, cope with life positively after suffering a negative event. Midwifery has been defined as 'emotionally demanding'; midwives with an higher levels of resilience experience higher levels of subjective well-being (SWB). The aim of this study was to evaluate the relationship between resilience and SWB amongst midwives.

Materials and methods:

Data were collected using a questionnaire, distributed between September 2018-January 2019 in hospitals in the Tuscany region (Italy). For evaluation of SWB, we used OECD scale (2013) evaluating three items: actual happiness (AH); emotive wellbeing (BE) composed of positive (PA) and negative affect (NA) and life satisfaction (LS). Also, job satisfaction (JS) was evaluated. Resilience (RS) was evaluated using the Italian version of the Resilience Scale by Wagnild and Young. All items were expressed on the Likert scale, statistical analysis was performed with Minitab 18.

Results:

In total 123 questionnaires were analyzed. The average scores were: AH: 6.9±1.8; BE: 5.9±1.6; PA: 6.0±1.8; NA: 4.2±2.1; LS: 7.1±1.6; JS: 6.5 ± 2.4. Average R was 130.3±18.1. RS was correlated ($p < 0.001$) to AH (Coef = 0.4), PA (Coef = 0.4), BE

(Coef = 0.3) e LS (Coef = 0.4). The sample was divided into three groups according to RS: low (LR)<116, medium (MR):116-139 and high (HR) $\geq$140. MR represented 44%, followed by HR (35%). AH, PA, BE values were significantly higher in the HR group (ANOVA; Tukey; $p < 0.001$). For NA the highest values were observed in the LR group, but the difference was not significant. LS resulted significantly lower in LR group (ANOVA; Tukey; $p < 0.001$) and JS was significantly higher in medium resilience group in confrontation to other two groups (ANOVA; Tukey; $p < 0.001$).

Conclusions:

Our results confirmed, that the higher levels of RS influenced positively almost all components of SWB (AH, PA, BE, LS). On the other hand to achieve a higher level of JS the level of RS should not be nor too high, nor too low.

Key messages:

- Midwifery has been defined as 'emotionally demanding', higher levels of resilience influenced positively almost all components of subjective wellbeing.
- The medium resilience was correlated to higher level of job satisfaction.

Serum modified HDL was associated with cardiovascular disease in a Japanese community-based cohort

Tomonori Okamura

T Okamura[1], M Sata[1], M Iida[1], A Kakino[2], S Harada[1], A Hirata[1], Y Usami[2], D Sugiyama[1], T Sawamura[2], T Takabayashi[1]
[1]Preventive Medicine and Public Health, Keio University School of Medicine, Tokyo, Japan
[2]Molecular Pathophysiology, School of Medicine, Shinshu University, Matsumoto, Japan
Contact: okamura@z6.keio.jp

Background:

Previous studies have shown that high density lipoprotein (HDL) is protective against cardiovascular disease (CVD). However, recent studies suggested that function of HDL was more important than HDL cholesterol levels. The present study aimed to clarify the relationship between modified HDL levels and CVD incidence.

Methods:

LOX-1 (lectin-like oxidized LDL receptor) is the receptor that mediates modified LDL (low density lipoprotein) activity; however, some lipoproteins with apolipoprotein A1 (Apo A-1) are also bonded to LOX-1. In this study, serum LOX-1 ligand containing Apo A-1 was defined as modified HDL, which were measured by our new development method. We conducted a nested case-control study in a Japanese cohort study, involving 11,002 community dwellers. During 4.0 years follow-up, we observed 127 new CVD onsets. For each CVD case, age and sex matched three controls were randomly selected ($N = 381$). Serum samples collected at baseline survey stored at $-80\,^{\circ}$C were used for the measurement of modified HDL. We estimated multivariable-adjusted odds ratio (OR) and 95% confidence interval (CI) for the association between modified HDL levels and CVD by conditional logistic regression.

Results:

Modified HDL levels were associated with increased risk of CVD (OR for one unit increase of log transformed modified HDL, 2.05: 95% CI, 1.16-3.62) after adjustment for body mass index, hypertension, diabetes, LDL cholesterol, HDL cholesterol, lipid lowering agents, chronic kidney disease, smoking and alcohol drinking. The magnitude of OR was almost equivalent to those of hypertension and diabetes, which were 2.33 (95% CI, 1.37-3.98) and 2.61 (95% CI, 1.48-4.59), respectively. On the other hands, other lipids markers showed relatively weak associations with CVD.

Conclusions:

Serum modified HDL, i.e., LOX-1 ligand containing Apo A-1, might be a novel predictive marker for CVD in apparently healthy individuals.

Key messages:

- Recent epidemiologic studies suggested that function of high-density lipoprotein (HDL) was more important than HDL cholesterol level itself to predict cardiovascular disease.
- Modified HDL measured by a novel cell-free, non-fluorescent method as LOX-1 ligand containing Apo A-1, was a predictive marker for CVD after adjusting for other traditional risk factors.

8.S. Health workforce

Pharmacist to improve hypertension management: concordance between Europe and North America

Valérie Santschi

D Anker[1], RT Tsuyuki[2,3], G Paradis[4], A Chiolero[1,4], V Santschi[5]
[1]Institute of Primary Health Care (BIHAM), University of Bern, Bern, Switzerland
[2]EPICORE Centre, University of Alberta, Edmonton, Canada
[3]Faculty of Medicine and Dentistry, University of Alberta, Edmonton, Canada
[4]Department of Epidemiology, Biostatistics, McGill University, Montreal, Canada
[5]La Source, School of Nursing Sciences, HES-SO University of Applied Sciences and Arts of Western Switzerland, Lausanne, Switzerland
Contact: v.santschi@ecolelasource.ch

Problem:

Hypertension is highly prevalent but remains poorly controlled, notably in European countries where control rates are frequently worse than in Canada and the United States. One innovative solution for improving hypertension management is team-based care (TBC) with the involvement of a pharmacist.

Description of the problem:

We systematically compared recommendations for TBC in hypertension management in recent European (ESC/ESH), American (ACC/AHA), and Canadian (Hypertension Canada) guidelines and pinpointed potential roles and responsibilities of pharmacists.

Results:

The three guidelines recommend TBC for the management of hypertension, with the ACC/AHA Guidelines giving a stronger emphasis by providing a more exhaustive definition of TBC and by describing the composition of the team. The three guidelines assign roles and responsibilities in hypertension management at the team level, but no firm role is defined for each specific team member. The three guidelines also refer to evidence showing that the pharmacist's involvement can embrace several activities, that is, diagnosis of hypertension, blood pressure monitoring, medication management, education of patient and health care providers, and communication and organization within the care team. Recent systematic reviews have shown that a pharmacist's involvement in these steps in hypertension management improves hypertension control compared to standard of care.

Lessons:

International guidelines, including European ones, recommend using TBC in hypertension management, based on strong evidence that a pharmacist's involvement improves hypertension control.

Key messages:

- International guidelines recommend TBC and the involvement of pharmacists to improve hypertension management.

- Programs and policies to improve hypertension control in European countries should consider the involvement of pharmacists.

Teaching medical students multi-disciplinary team work through integrated course

Rabiga Khozhamkul

R Khozhamkul[1], L Kosherbaeva[1], A Kumar[1], K Bayildinova[2], S Sydykova[3]
[1]School of Public Health, Kazakh National Medical Unviersity, Almaty, Kazakhstan
[2]Kazakh National Medical University, Almaty, Kazakhstan
[3]Ministry of Health of Republic of Kazakhstan, Almaty, Kazakhstan
Contact: r.khozhamkul@kaznmu.kz

Healthcare reform in Kazakhstan has created a basis for shift from disease centered approach to person and prevention centered healthcare. In order to embrace that agenda, Kazakh National Medical University has developed and implemented project-based course in General practitioners (GP) training program at the internship level. The objective of the program is to acquire skills on work in multidisciplinary teams for health promotion and research. We used project-based learning pedagogical framework for the course. 6 ECTS course was integrated into curriculum of internship in the track of GP training, at the 7th year, for 1 semester. During the course participants were introduced to the theoretical concepts of health promotion and disease prevention program planning, created and implemented their own project. At the end of the course students were required to do a poster presentation. Main outcomes of educational program were that students will (1) gain understanding of health promotion and disease prevention concepts, (2) would be able to implement research skills, (3) and work in integrated multidisciplinary team. To measure results, we disseminated self-administered online based questionnaire for students after the last class (n = 122). Questionnaire consisted of 4 domains: self-development and team work, teaching, context and clinical practice. There were 17 domains that students assessed with 5-point Likert scale, where 1- strongly disagree, 2- disagree, 3- agree to some extent, 4 - agree, 5 - strongly agree. Questionnaire also included 1 open - ended question for overall comments on the course and demographic questions. The response rate was 68,8% (n = 84), overall satisfaction rate was 77.6% (3.88 out of 5), rate on team work and practical work was 86% (4.3) and 83.6% (4.18). Comments of students showed that there is still not enough understanding on integrated person-centered primary healthcare approach and lack of integrated team work at clinical sites.

Key messages:

- Education of future general practitioners should include training on teamwork in integrated teams and health promotion.
- Project based learning helps training multi-disciplinary team work skills not only within students but also in teams at involved sites.

Final clinical practicum of nursing education and transition experience of new nurses

Anu-Marja Kaihlanen

A-M Kaihlanen[1], M Elovainio[1,2], L Salminen[3], E Haavisto[3,4], T Sinervo[1]
[1]National Institute for Health and Welfare, Helsinki, Finland
[2]Department of Psychology and Logopedics, University of Helsinki, Helsinki, Finland
[3]Department of Nursing Science, University of Turku, Turku, Finland
[4]Satakunta Hospital District, Pori, Finland
Contact: anu.kaihlanen@thl.fi

Background:

Challenges in transitioning from a student to a registered nurse may contribute to new nurses high turnover rates. Final clinical practicum (FCP) before graduation is known for its importance in preparing students for the transition but little is known about the specific elements of FCPs essential for successful transition. We examined the associations between multiple FCP elements and transition experiences in new nurses and whether work characteristics modified these associations.

Methods:

The data were collected in 2018 with electronic survey. The sample comprised 712 Finnish nurses graduated within the last two years. Linear regression analyses was used to examine the association of five FCP elements (Preparing for demands; Being part of team; Systematicness of FCP; Teacher involvement; Quality of supervision) with the transition experience that was measured with four scales demonstrating its emotional, physical, socio-developmental and intellectual domains. Work characteristics were defined based on demand-control -model and multiple potential confounders were considered.

Results:

Several associations were found between the FCP elements and the four transition indicators (psychological distress, sleep problems, role conflict/ambiguity and perception of transition/educational preparation). Systematicness of FCP was, however, the only element associated with all the transition indicators, whereas quality of supervision was not associated with any. Multiple interactions were also detected between the FCP elements and job demands.

Conclusions:

Our results suggest that FCP experiences reflect to new nurses' first years of employment. Especially systematic planning and implementation of FCP, collegial work atmosphere and an opportunity for students to become an active member of the work community should be ensured for promoting a smoother transition from student to nurse. This could increase the chances to retain new nurses in the health care workforce.

Key messages:

- Well planned and implemented final clinical practicums with an opportunity to become an active member of professional team could help nursing students to obtain a smoother transition into nurses.
- The benefits of having a good final clinical practicum experience may be squandered if considerably high level of job demands (e.g. timepressure) is experienced in the first years of employment.

Health Communication needs of health professionals in Europe – the H-COM cross sectional study

Konstantina Zota

K Zota[1], P Karnaki[1], A Veloudaki[1], T Tsiampalis[1], A Linos[1]
[1]Institute of Preventive Medicine, Environmental & Occupational Health, Marousi, Greece
Contact: d.zota@prolepsis.gr

Background:

Effective communication between Health Professionals (HP) and patients is crucial for the overall functioning of the healthcare system with positive impacts on readmission rates, treatment outcomes, adherence and costs. However, health communication training is limited especially during medical training. In the framework of the EU H-COM project an exploration of health communication needs and gaps and preferred training methods was performed among HP.

Methods:

A cross-sectional online survey was conducted among 702 health professionals (Physicians: n = 315; Nurses: n = 258; Other: n = 129) through a purpose made questionnaire available in English, Greek, Polish, Spanish and German.

Results:

Health communication training is considered necessary for physicians (89.8%) and nurses (89.7%), although 42.4% of them never received relevant training in the past. Professional status ($p < 0.001$), age ($p = 0.079$), gender ($p = 0.090$) and years of experience ($p = 0.012$) affected the likelihood of not having received such training, with physicians, HPs aged 45-54 years old, males and those having 6-10 years of experience being most in need. At least 50.0% reported encountering problems in communicating with their patients and facing several barriers either in primary health care settings and hospitals or in private practice. The ability to listen and answer patients, deliver bad news and obtain medical history were the most important communication skills identified, while the most suitable training method was learning relevant practical skills. The availability of such trainings is reported as being fair or poor at all educational levels by the majority.

Conclusions:

Health communication training is considered important although currently not available to the extent needed. This research provides evidence concerning the preferred type, frequency and mode of health communication training providing also insight on differences between various HPs.

Key messages:

- Health communication training is crucial but inadequate in Europe. There are specific training needs and preferences among HP which need to be considered.
- Health communication training needs to be adapted and tailored to professionals' age, experience and status.

Engaging a wider public health workforce: bringing public health into architecture education

Rachael Marsh

R Marsh[1,2], *P Pilkington*[1,2], *E Marco*[3], *L Rice*[2,3]
[1]Department of Health and Social Sciences, University of the West of England, Bristol, UK
[2]WHO Collaborating Centre, University of the West of England, Bristol, UK
[3]Department of Planning and Architecture, University of the West of England, Bristol, UK
Contact: rachaelmarsh@nhs.net

Background:

Current public health challenges necessitate the closer working of public health with built environment professionals. Despite growing evidence of benefits, there remains little progress in practice. Architects can play a key role in ensuring urban and building design is health promoting, however there is no requirement to teach health by architectural accreditation bodies across Europe.

Objectives:

In the United Kingdom in 2010, the Public Health Practitioner in Residence programme (PHPiR) was established to address this situation. Public health professionals are embedded within the Faculty of Environment and Technology at the University of the West of England, and contribute to research, pedagogic programme development, teaching and mentoring. The aim was to embed public health concepts and issues into architecture training, to empower the profession as part of the wider workforce, to improve health and wellbeing when designing buildings and places. The PHPiR was evaluated using the Reach, Effectiveness, Adoption, Implementation, Maintenance (RE-AIM) framework. Data was collected (questionnaires, focus group, semi-structured interviews, programme documentation) on a Masters of Architecture cohort (N = 34) at intervals from 2011-2019 to see if the PHPiR has long lasting effects as students enter practice.

Results:

Public health concepts including; inequalities, life course approach, and social capital, became embedded into the architecture curriculum. Projects produced had increased reference to wider health promoting issues and participants thinking shifted from the building itself to who would use the building, suggesting the intervention achieved its aims.

Conclusions:

The PHPiR offers a novel approach for built environment professions to better understand public health issues and the relevance to their chosen fields. This model could be applied to other courses and replicated in educational institutions and public health training programmes across Europe.

Key messages:

- The PHPiR influenced the architecture curriculum, improved architects understanding and public health issues and concepts, and empowered them to create more health promoting environments.
- Embedding public health professionals into training for other disciplines may be an effective, sustainable method for increasing the wider public health workforce.

Delegation of medical services to specially trained medical practice assistants

Susanne Schnitzer

Contact: susanne.schnitzer@charite.de

Background:

Germany is one of the countries most affected by demographic change. Meaning the shift towards the population being older is growing. At the same time, the number of doctors is declining. In order to ensure adequate care in Germany, the delegation of medical services to specially trained medical practice assistants (MPAs) is currently discussed. The aim of this study was to assess the attitudes of the German population towards medical delegation.

Methods:

The analysis was based on a population survey of 6.105 German-speaking residents aged 18 years and over. Associations between respondents' attitudes towards the delegation and social determinants (age, gender, education, employment status, region, self-rated health) were assessed using standardised questionnaires. Bi- and multivariate (logistic regression) analyses were performed.

Results:

In case of a chronic disease half of the German-speaking population (51. 8%) would accept getting treated by a MPA. More older participants (65 years and above) than younger participants (18 to 34 years old) (OR: 1,64; KI [1,24-2,18]), more lower than higher educated participants (OR: 1,20; KI [1,04-1,39]) and more non-German than German participants (OR: 1,61; KI [1,24-2,10]) are significantly more likely to not accept medical delegation in case of a chronic disease. Discussion: In the debate on delegation models the present results should be taken into account in order to be able to address relevant target-groups. Further qualitative studies that investigate the reasons for the critical view on delegation are recommended.

Key messages:

- Approximately 50% of the German-speaking study population would accept treatment by a MPA for chronic disease.
- Especially older study participants, lower educated people and non-German participants would not accept medical delegation in case of a chronic disease.

Human Resources for Health challenges during health emergencies—low number of workers in El Salvador

Mirna Amaya Amaya

MP Amaya Amaya[1,2]
[1]Department of Environmental and Global Health, University of Florida, Gainesville, USA
[2]Emerging Pathogens Institute, University of Florida, Gainesville, USA
Contact: mirnaaa@ufl.edu

El Salvador is one of the 57 countries considered to be in Human Resources for Health (HRH) crisis according to the World Health Organization (WHO). El Salvador's healthcare worker density is 1.95 health professionals per 1,000 population, with even lower numbers in certain departments of the country. There have been improvements in the distribution of healthcare workers since 2010; however, on average it has remained ''in crisis'' based on the 2006 World Report

//blrnas3/cenpro/ApplicationFiles/Journals/OUP/EURP/Vol00000/190194/Comp/APPFile/OP-EURP190194.3d [24.10.2019–6:59pm] [299–384] Paper: OP-EURP190194

definition. The increase in vector borne diseases in the region, has resulted in an overwhelmed vector control system and public health sector in many Central American countries. This study aims to analyze whether the healthcare workers identify the numbers of HRH as a factor that affects the health system response during health emergencies.

Through an extensive review of scientific literature, country reports, 16 meetings and 34 in depth semi-structured interviews with key stakeholders; this paper explores the challenges healthcare workers faced and how they were influenced by the numbers of available HRH during recent arboviral epidemics in El Salvador, using the recent Zika epidemic as a point of comparison.

The study findings suggest that some of the barriers that the health workforce identified during health emergencies include factors related to the low availability of HRH such as feelings of tiredness, being overwhelmed, as well as a need to rely on doctors in their social year in some areas of the country. Despite this, they also recognize that the recent intersectoral work done by the government and the Ministry of Health, has helped to overcome the obstacles of a low healthcare workforce by involving other sectors of society into the emergency response. Therefore, there is not a clear consensus on how the low number of HRH affect the health emergency response.

Key messages:

- The study findings suggest that some of the barriers that the health workforce identified during health emergencies include factors related to the low availability of HRH.
- They also recognize that the recent intersectoral work done by the government and the Ministry of Health, has helped to overcome the obstacles of a low healthcare workforce.

Informal carer in Portugal: moving towards political recognition in Portugal

Ines Fronteira

I Fronteira[1], *J Simoes*[1], *G Augusto*[1]
[1]Global Health and Tropical Medicine, Institute of Hygiene and Tropical Medicine, Lisbon, Portugal
Contact: ifronteira@ihmt.unl.pt

Informal care represents around 80% of all long term care provided in EU countries. Nevertheless, the needs for this type of care are expected to increase in the coming years in all OECD countries.

Portugal is among the OECD countries with the highest ageing index (21.5% of the population was older than 65 years in 2017) due to high life expectancy and low fertility rates. As this demographic trend establishes, Portugal is expected to have more than 40% of the population over 65 years in 2037, and the expected prevalence of dementia is 3%, in 2050. In 2015 there were 2.1% of people over 65 receiving long-term care, representing 52% of all long-term care users. Around 38% were receiving care at home. It is estimated that 287,000 people in Portugal depend on informal carers.

The agenda towards the official recognition of informal cares has been push forward in the country. Since 2015, several recommendations have been issued by the Parliament as well as legislative initiatives and a proposal for a Status of the Informal Carer is currently under discussion. We analyse the process of formulation of this policy in terms of sectors and stakeholders involved, definition and scope of informal carer, rights and obligations, role of the person being cared for, formal protection (e.g., labor, social, financial, training) and implementation.

Recognition of the informal carer is a sector wide approach. One of the main features is the economic, social and labor protection mainly through reconciliation between work life and caring activities and promotion of the carer's well being. Notwithstanding, and from a health system perspective, community health teams are to be the focal point for informal carers, supporting and providing specific training whenever needed. Despite its relevance, informal care should not be professionalized and responsibility of care should not be shifted from health services to informal carers.

Key messages:

- Needs for informal care are expected to increase in the coming years in OECD countries.
- Recognition of the informal carer is a sector wide approach.

Older Patients in Emergency Departments. Challenges from the health care providers' perspective

Johannes Deutschbein

J Deutschbein[1], *M Möckel*[2], *L Schenk*[1]
[1]Institute of Medical Sociology and Rehabilitation Science, Charité - Universitätsmedizin Berlin, Berlin, Germany
[2]Departments of Emergency Medicine, Charité - Universitätsmedizin Berlin, Berlin, Germany
Contact: johannes.deutschbein@charite.de

Background:

Patients aged 65 and above are the fastest growing patient population in Europe. This is one of greatest challenges for almost all health services providers, including acute hospitals and their Emergency Departments (ED). As of today, older patients represent up to 30% of all ED patients, it is estimated. However, it is largely unclear to what degree EDs are currently prepared for older patients and how they need to adjust. This study analyses the present situation from the perspective of health care professionals caring for older ED patients.

Methods:

The study was embedded in a mixed methods design using qualitative expert interviews. N = 25 semi-structured, guided interviews were conducted with professional health care providers from 7 Berlin EDs (physicians, nurses), and adjacent health care sectors such as nursing homes, rehabilitation clinics, and medical practices. Interviewees were asked about their daily experiences with older ED patients and their ideas of health care deficits and potentials. Data was analyzed using content analysis and hermeneutics.

Results:

Health care providers assess the ED care situation for older patients and the necessity of adjustments in different ways but mostly as deficient. EDs are described as not elderly-friendly and partly as hazardous: older patients are at risk of adverse events such as developing a delirium. Risk factors are prolonged length of stay, the busy and noisy ED setting, and falls hazards. In general, ED staffing is not adequate to care for older patients with complex needs.

Conclusions:

Considering demographic change, German Eds need to concentrate on the growing number of oder patients and their specific needs. Further research and development of specific care concepts for older ED patients is strongly needed. Potential adjustments of ED structures and care concepts also need to involve patients' experiences and subjective needs. However, data on the patient perspective is still missing.

Key messages:

- Older patients and demographic change represent great challenges for EDs.
- Care concepts need to be developed to meet older patients needs and to avoid risks of adverse events.

Attitudes of social welfare professionals of the concept of positive health in the Netherlands

Cindy De Bot

N van der Meer[2], *JAJ Dierx*[1]
[1]Living in Motion Research Group, Avans University of Applied Sciences, Breda, Netherlands
[2]Avans Bachelor of Social Work, Avans University of Applied Sciences, Breda, Netherlands
Contact: cma.debot@avans.nl

The current definition of health from the World Health Organisation seems to no longer meet the changes in the current Dutch health system. An alternative approach which puts emphasis on health, not disease, is Positive Health. The current and future developments in the health care system in the Netherlands are demanding different mentality and practice methods of social work and welfare professionals. In order to measure the extent to which there is support for positive health among the social welfare professionals, research must be carried out into the attitude of the professionals. In this study, the attitudes towards the concept of Positive Health of social welfare professionals are examined.

Methods:

A mixed-method study was used, in which both quantitative and qualitative data were collected. By means of a survey (n = 128) and semi-structured interviews (n = 9), the attitude and working method of social workers were explored.

Results:

Social welfare professionals find that the concept Positive health can contribute to an increase in resilience and self-management in citizens and patients. However, social welfare professionals wonder if all citizens and patients have the ability to self-manage skills. In addition, social welfare professionals think all domains of the positive health concept are regarded as important in defining health.

Conclusions:

The concept of positive health is in line with the attitude of social welfare professionals and has support for implementation. In order to introduce the concept Positive Health further and to make it stand out in the social welfare domain, more attention needs to be paid to disseminating the concept, broadening the knowledge of the professionals and practical tools for practice.

Key messages:

- Positive Health concept connects professionals in health care and welfare.
- The concept of positive health is in line with the perceptions of health of the social welfare professionals.

9.R. Child health

Parental health literacy and health behaviors in children: a 2017 cross-sectional survey in Germany

Elke de Buhr

E de Buhr[1,2], *A Tannen*[1]

[1]Institute for Health and Nursing Science, Charité Universitätsmedizin Berlin, Berlin, Germany

[2]School of Public Health and Tropical Medicine, Tulane University, New Orleans, USA

Contact: elke.debuhr@gmail.com

Background:

Health literacy (HL) is closely associated with leading health indicators. Parents represent a critical subgroup among the adult population since they are not only responsible for their own health but also for the health of their children. Previous research suggests that parents with low HL are less likely to meet the preventive and health care needs of their children but the relationship between parental HL and child health is not yet well understood.

Methods:

A cross-sectional survey was implemented in 2017 in 28 public schools in Germany. The parent questionnaire was completed by 4217 caregivers and included the short form of the HLS-EU-Q16. The child questionnaire examined health knowledge, behaviors and outcomes. For children under 11 years, the caregiver reported on behalf of their children (N = 1518). In all other cases, the children completed the questionnaires (N = 2776). Bivariate and multivariate analyses were carried out.

Results:

Among the interviewed parents, 45.8% showed a problematic or inadequate HL. Parents with higher HL reported a better subjective health and quality of life, and they judged their children as being healthier. The major determinant of high parental HL was socio-economic status ($r = .088^{***}$). High parental HL was associated with positive health behaviors in children including higher consumption of fruits and vegetables, fewer sweetened beverages, regular tooth brushing and more physical activity. The relationships between parental HL and smoking, alcohol consumption, sexual activity among children and children's weight were not significant.

Conclusions:

The results confirm a relationship between low parental HL, SES and some problematic health behaviors in children. Strengthening the HL of vulnerable parents may contribute to improved health outcomes particularly in the areas of children's nutrition, exercise and dental health, and parents should be integrated in school-based activities of health promotion and prevention.

Key messages:

- There is a strong statistical relationship between parental health literacy and socio-economic status.
- Parental health literacy is associated with child health behaviors (e.g., nutrition, exercise).

Parents' socioeconomic position, psychological problems, and emotional neglect in childhood

Hrafnhildur Gunnarsdottir

J Löve[1], *K Mehlig*[1], *Å Källström*[2], *G Hensing*[1], *H Gunnarsdottir*[1,3]

[1]Department of Public Health and Community Medicine, University of Gothenburg, Gothenburg, Sweden

[2]School of Law, Psychology and Social Work, Örebro University, Örebro, Sweden

[3]Department of Health Sciences, University West, Trollhättan, Sweden

Contact: hildur.gunnarsdottir@gu.se

Background:

Despite high prevalence and severe consequences for health and wellbeing, emotional neglect (EN) in childhood is a neglected topic in epidemiological research. To enable prevention of neglect knowledge is important about conditions related to EN such as parental individual characteristics and social/economic situation. Aim to investigate the relationship between parental socioeconomic position (SEP), psychological problems, and EN in childhood.

Methods:

The sample comprised Swedish women, N = 976, mean age 22. EN was assessed by five indicators: maternal/paternal rejection, maternal/paternal lack of time, and occurrence of domestic violence. The associations between parental SEP/psychological problems and EN were examined by logistic regressions.

Results:

The odds of experiencing domestic violence in childhood was higher among women with parents with low (OR 3.1 95% CI 1.1-8.5) or medium SEP (OR 3.4 95% CI 1.7-6.9). Women who reported maternal psychological problems had higher odds of maternal rejection (OR 6.8 95% CI 3.5-13.0), maternal lack of time (OR 2.4 95% CI 1.2-5.0) and paternal rejection (OR 1.9 95% CI 1.1-3.5). Women who reported paternal psychological problems had higher odds of perceiving their father as rejecting (OR 4.0 95% CI 2.1-7.7), not having enough time for them (OR 4.9 95% CI 2.3-10.6), and experiencing domestic violence (OR 4.9 95% CI 2.1-11.6).

Conclusions:

Lower SES was not related to EN in form of parental rejection or lack of time but to the occurrence of domestic violence. Parental psychological problems were related to all indicators of EN but differently among mothers and fathers. Public health initiatives aiming at supporting parents should also embrace parental psychological wellbeing.

Key messages:

- Emotional neglect was clearly related to parental psychological problems but not parental socioeconomic status.
- Gendered structures need to be considered in studies of emotional neglect.

Parental mental vulnerability and use of healthcare services in infants

Signe Heuckendorff

S Heuckendorff[1], MB Johansen[2], C Overgaard[4], SP Johnsen[3,5], K Fonager[1,5]
[1]Department of Social Medicine, Aalborg Universitetshospital, Aalborg, Denmark
[2]Unit of Clinical Biostatistics, Aalborg Universitetshospital, Aalborg, Denmark
[3]Danish Center for Clinical Health Services Research, Aalborg Universitetshospital, Aalborg, Denmark
[4]Department of Health Science and Technology, Aalborg University, Aalborg, Denmark
[5]Department of Clinical Medicine, Aalborg University, Aalborg, Denmark
Contact: s.heuckendorff@rn.dk

Background:

Parental mental illness has been associated with a number of consequences for the health and use of healthcare services of the child. However, most research has focused on maternal depression. Research examining the impact of paternal mental vulnerability (MV) as well as different degrees of MV are needed to plan interventions. Therefore, the aim of this study was to examine the association between different categories of individual and combined parental MV and the child's use of healthcare services the first year of life.

Methods:

A population-based birth cohort study was conducted including all Danish children born from 2000-2016 using the Danish national registers. Exposure was parental MV of three categories according to the degree of MV: Group 1 ''minor MV'' with mental related contacts to primary healthcare and/or prescribed psychopharmaceuticals, group 2 ''moderate MV'' and group 3 ''severe MV'' both with contacts to psychiatric hospital. Outcome was contacts to GP the first year of life expressed as incidence-rate ratios (IRR) using Poission's regression analyses.

Results:

The analyses included 952,709 children. 21% of the mothers and 11% of the fathers were in the MV groups. Parental MV (any parent, any MV-group) was associated with an increased risk of GP contacts daytime and out-of-hour contacts. If both parents were classified as group 1 MV, IRR were 1.21 (CI95 1.20-1.22). IRR were 1.18 (1.17-1.18) resp. IRR 1.05 (1.04-1.06) if only the mother resp. father were in MV group 1. The same pattern were seen for out-of-hour contacts; IRR 1.28 (1.26-1.31) for both parents in group 1 and IRR 1.19 (1.18-1.20) resp. IRR 1.09 (1.08-1.11) for the mother resp. father.

Conclusions:

Maternal and paternal MV were associated with an increased risk of GP contacts daytime and out-of-hour contacts although maternal MV had the highest risk. Even minor MV had an impact on healthcare contacts and the risk increased further if both parents were classified as minor MV.

Key messages:

- Both maternal and paternal mental vulnerability has an impact on the child's healthcare contacts.
- Our results indicate the need for a focus also on minor mental vulnerability in the planning of interventions.

The effectiveness of a web-based Dutch parenting program to prevent overweight in children age 9-13

Emilie Ruiter

ELM Ruiter[1], GRM Molleman[1], GAJ Fransen[1], K van der Velden[1], RCME Engels[2]
[1]Academic Collaborative Center AMPHI, Integrated Health Polic, Radboudumc, Nijmegen, Netherlands
[2]Executive Board, Erasmus University, Rotterdam, Netherlands
Contact: emilie.ruiter@radboudumc.nl

Background:

We developed a web-based parenting program for parents entitled ''Making a healthy deal with your child''. This e-learning program can be incorporated into existing prevention programs, thereby improving these interventions by reinforcing the role of parenting and providing parents with practical tools for use in everyday situations in order to stimulate a healthy lifestyle.

Methods:

The effectiveness was studied in a two-armed cluster randomized controlled trial. We recruited 548 parent-child dyads of children 9-13 years in the Netherlands who participated in an existing school-based overweight prevention program. Primary outcomes included the child's dietary and sedentary behavior, and level of physical activity. Secondary outcomes included general parenting style, specific parenting practices (set of rules, modeling, monitoring), and parental self-efficacy. Multilevel multiple regression analyses in Mplus were conducted.

Results:

87% of the parent-child dyads participated in the study and 47% of the parents in the intervention group completed 2 or more episodes of the e-learning. The score that parents gave to the e-learning is a 7.Main effect analyses showed in the intention-to-treat analyses that the the parents in the intervention group have more strict rules regarding eating snacks (0.046) and children of parents in the intervention group drink more milk ($p = 0.018$) and less sugar sweetened beverages ($p = 0.024$). The completers only analyses showed that the children of parents in the intervention group eat more vegetables and fruit, drink more water and less sugar sweetened beverages, and had less screentime than the children in the control group.

Conclusions:

The e-learning program showed small indications to be effective. A second effectiveness study is currently being investigated. If the e-learning proves to be effective it can be easily incorporated into existing overweight prevention programs for children, as well as activities regarding Youth Health Care.

Key messages:

- The e-learning can easily incorporated into existing overweight prevention programs for children.
- www.gezondeafsprakenmetjekind.nl

Early socioeconomic circumstances and cardiometabolic health in 10-year-old children

Fraga Sílvia

S Soares[1,2], AC Santos[1,2], F Soares Peres[1], H Barros[1,2], S Fraga[1, 2]
[1]EpiUnit, Instituto de Saúde Pública, Universidade do Porto, Rua das Taipas, Porto, Porto, Portugal
[2]Dep. Ciências da Saúde Pública e Forenses e Educação Médica, Faculdade de Medicina, Porto, Portugal
Contact: silviafraga14@gmail.com

Background:

Social adversity is thought to become biologically embedded during sensitive periods of development, setting children on a trajectory of increased risk for later chronic diseases. Thus, social differences are expected to be expressed as biological alterations and might have their origins in early life. Therefore, we aim to estimate the association between early socioeconomic position (SEP) and cardiometabolic health during childhood.

Methods:

Data from 2962 participants in the population-based birth cohort Generation XXI, from Porto, Portugal, was collected following standardized procedures at all study waves. Early SEP definition included household income, parental education and occupation at child's birth. Cardiometabolic health was characterized at the age of 7 and 10, considering the triglycerides, cholesterol, fasting glucose, body mass index, systolic and diastolic blood pressure. Logistic regression was used to estimate the association between early SEP and a favorable cardiometabolic health profile.

Results:

A favorable cardiometabolic profile was observed in almost half of participants at both ages, particularly among high SEP children who remain more frequently without alterations. For girls, higher paternal education at 7 years (OR:1.49;95%CI:1.03-2.15) and higher SEP at 10 were associated with better cardiometabolic health profile. In boys, a better cardiometabolic health profile was observed with increasing levels in maternal and paternal education and occupation, but at the age of 10, social differences were more evident according to parental education.

Conclusions:

We provide evidence that children from more advantaged SEP at birth have an increased likelihood of presenting better cardiometabolic health at early ages. Social differences in cardiometabolic health biomarkers are already found in childhood, suggesting that the short-term impact of early life SEP on the physiology dysregulation takes place already in the first decade of life.

Key messages:

- Social differences in cardiometabolic health are already established in the first decade of life, with children from higher SEP presenting a better cardiometabolic health.
- Cardiovascular events are not expected to develop during childhood, however the underlying atherosclerotic process might already be in course as social differences appear to widen with age.

Early socioeconomic circumstances and adverse childhood experiences in 10-year-old children

Fraga Sílvia

F Soares Peres[1], *S Soares*[1,2], *H Barros*[1,2], *AC Santos*[1,2], *S Fraga*[1,2]
[1]EPIUnit, Instituto de Saúde Pública da Universidade do Porto, Porto, Portugal
[2]Departamento Ciências da Saúde Pública e Forenses e Educação Médica, Faculdade de Medicina, Universidade do Porto, Porto, Portugal
Contact: silviafraga14@gmail.com

Background:

Evidence showed that adverse childhood experiences (ACEs) are associated with the development of disease later in life and premature death. Examining the occurrence of these experiences at early ages would contribute to intervene and therefore to reduce health inequalities. This study aimed to assess the prevalence of ACEs among 10-year-children and to examine its association with early socioeconomic circumstances.

Methods:

At the fourth wave of the population-based birth cohort Generation XXI, from Porto, Portugal, 5153 children completed a self-report questionnaire on 9 experiences related to household dysfunction and physical and emotional abuse. Socioeconomic circumstances included household income, maternal and paternal education, and history of parental unemployment. Logistic regression was performed to calculate the Odds Ratios (OR) and 95% Confidence Intervals (95%CI).

Results:

A high prevalence of physical and emotional abuse was reported by children from low socioeconomic circumstances. A graded relationship between socioeconomic circumstances and cumulative ACEs was observed, for instance, low household income was associated with increased number of ACEs (one event [OR = 1.10; 95%CI: 0.89-1.36], two events [OR = 1.41; 95%CI: 1.15-1.73], three events [OR = 1.67; 95%CI: 1.34-2.06], and four or more events [OR = 2.05; 95%CI: 1.64-2.55]). Also, living with one parent or none of them increased the likelihood of reporting multiple ACEs (OR = 5.50; 95%CI: 4.23-7.13).

Conclusions:

Children from low socioeconomic circumstances were more likely to report multiple adverse experiences in the first decade of life. These findings support that children from less advantaged environments might be at a higher risk of co-occurrence of adverse experiences during their childhood.

Key messages:

- Prevalence of ACEs is high among 10-year-old children and is associated with low socioeconomic circumstances.
- Social inequalities in children should be prioritized by public health policy.

Spatial analysis and mapping of child malnutrition in Burkina Faso

Ying-Chih Chuang

Y Chuang[1]
[1]School of Public Health, Taipei Medical University, Taipei, Taiwan
Contact: yingchih@tmu.edu.tw

Background:

Approximately 45% of all child deaths are associated with malnutrition in sub-Saharan Africa. However, information on the geographical variations of child malnutrition in Burkina Faso is limited. This study examined the geographical distribution and the community characteristics associated with child malnutrition in Burkina Faso using spatial regression analysis.

Methods:

Data from the 2011 Burkina Faso Demographic Health Survey were analyzed. A representative sample of 572 communities and 6,120 children under age of five were in the survey. A general Kriging interpolation method was used to generate spatial malnutrition patterns. The Local Indicator of Spatial Autocorrelation was used to identify particular communities clustering with high and low child malnutrition scores. In the spatial regression analysis, we used a two-step procedure combining generalized estimating equation models (GEE) and spatial lag modeling techniques.

Results:

The average rates of stunting and wasting were 32.48%, and 15.05%, respectively. Stunting hotspots were observed to be in the eastern and northeastern part of Burkina Faso (i.e. Oudolan, Séno), while high rates of wasting were observed in the central-north part. The results of the spatial regression analysis revealed lower stunting rates in communities with a higher percentage of households with improved sanitation. Communities with higher rates of professionally assisted births were associated with low wasting rates while communities with higher rates of households with low wealth index reported higher rates of wasting. Spatial lag models appeared to estimate the relationship between community-level risk factors and stunting and wasting more accurately than the ordinary least squares models.

Conclusions:

This study revealed significant geographical patterns and community factors associated with childhood malnutrition. These factors should be considered for future programs aiming at reducing child malnutrition in Burkina Faso.

Key messages:

- The study identifies spatial trends and contextual factors associated with child malnutrition in Burkina Faso.
- Public health programs should focus on the regions identified as hot spots of child malnutrition in Burkina Faso.

Social-emotional problems among Swedish three-year-olds: an Item Response Theory Analysis

Marie Lindkvist

M Vaezghasemi[1], *E Eurenius*[1], *L R Sundberg*[1], *A Ivarsson*[1], *S-A Silfverdal*[2], *M Lindkvist*[1,3]
[1]Department of Epidemiology and Global Health, Umeå University, Umeå, Sweden
[2]Depatment of Clinical Science, Pediatrics, Umeå University, Umeå, Sweden
[3]Statistics, USBE, Umeå University, Umeå, Sweden
Contact: marie.lindkvist@umu.se

Background:

Young children's social-emotional problems can have a long-term effect if not treated early. In order to deepen our knowledge about children's social and emotional functioning, we utilized the Ages and Stages Questionnaires: Social-Emotional (ASQ:SE) among 3-year-olds in Sweden aiming: 1) to identify ASQ:SE items that are most commonly endorsed by children with high level of social-emotional problems; and 2) to assess whether certain ASQ:SE items differs between boys and girls at the same level of social-emotional problems.

Methods:

During 2014-2017 data was collected from 7179 three-year-old children through Child Health Care in a northern county of Sweden within the Salut Child Health Promotion Programme. Item Characteristic Curve (ICC) and Differential Item Functioning (DIF) were used to identify the characteristics of children with high social-emotional problems and to determine whether an item exhibit uniform between boys and girls at the same level of social-emotional problems.

Results:

Items regarding interest in sexual words, too little sleep, disinterest in things around, unhappiness and self-injury were more commonly endorsed by children with high levels of social-emotional problems. Additionally, on the same level of social-emotional problem girls were more likely to score high in items regarding difficulties to occupy herself, clinging behaviour and repetitive behaviour while boys were more likely to score high in items regarding difficulty to name friends, difficulty to express feelings and destruction of things on purpose.

Conclusions:

This study has increased our knowledge about Swedish young children's social emotional functioning already at the age of three by detecting which items are most closely connected to high level of social-emotional problems and differences between boys and girls. However, whether the results detected in this analysis are reflecting their parents' expectations more than child behaviour requires further investigations.

Key messages:

- Children with high level of social-emotional problems were rated high on items regarding interest in sexual words, too little sleep, disinterest in things around, unhappiness and self-injury.
- On equal levels of social-emotional problems, girls were more often reported with internalizing problematic behaviours and boys were more often reported with externalizing problematic behaviours.

Are neighbourhood characteristics associated with physical activity levels in schoolchildren?

Gulin Kaya

Gulin Kaya[1], *Pinar Ay*[1], *Seyhan Hidiroglu*[1]
[1]Department of Public Health, Marmara University School of Medicine, Istanbul, Turkey
Contact: glnztrk@hotmail.com

Background:

Moderate-vigorous physical activity (MVPA) is an essential determinant of health for children. However 82% of children aged 11-17 years in Turkey are physically inactive. The objective of this study was to determine the prevalence of physical inactivity (PI) and sociodemographic and neighbourhood characteristics associated with PI among children aged 9-13 years.

Methods:

The population of this cross-sectional study was 5-7th grade students attending schools in a district of Istanbul. Two schools from urban and two from semi-urban localities were selected in order to capture different neighbourhood characteristics. Sample size was calculated as 344 assuming a difference of PI prevalence of 15% between neighbourhoods, an alpha error of 0.05, a power of 80%. Data were collected by child and parent questionnaires. PI was defined as < 60 minutes MVPA per day within the previous week. Neighbourhood characteristics were evaluated as physical (walkability levels, structure of sidewalks, presence of yards/parks, traffic density) and social (characteristics of social networks, trust among neighbours). Factors associated with PI were analysed by logistic regression.

Results:

A total of 334 students participated with a response rate 96%. The median age was 11 years and 52.9% were girls. The prevalence of PI was 79.3% (95%CI: 75.0-83.7%). Neighbourhood characteristics were not associated with PI ($p > 0.05$). PI was associated with ownership of mobile phones (OR: 1.96, 95%CI: 1.01-3.78), not being a member of a sports team (OR: 2.83, 95%CI: 1.21-6.58) and having ≤ 1 day of physical education classes at school (OR: 2.10, 95%CI: 1.08-4.09).

Conclusions:

The prevalence of PI is very high among schoolchildren. School-based interventions as motivating children to participate in sports teams and having physical education classes >1 times per week could be achievable strategies to combat PI. There is a need to adapt objective methods for assessment of neighbourhood characteristics.

Key messages:

- PI is a prevalent public health problem among school children in urban and semi-urban environments.
- The effectiveness of increasing structured physical activity levels at schools by utilizing sports teams and physical education classes should be evaluated in future studies.

Sexual maturation in girls: association with physical activity and sedentary behaviour

Veronique Desnouck

V Desnouck[1], *C Pedroni*[1], *M Dujeu*[1], *N Moreau*[1], *T Lebacq*[1], *E Holmberg*[1], *K Castetbon*[1]
[1]Service d'Information, Promotion, Éducation Santé (Sipes), Centre de Recherche, Brussels, Belgium
Contact: veronique.desnouck@ulb.ac.be

Introduction:

During adolescence, physical activity tends to decline, especially among girls. Adolescent inactivity is due in part to biological factors, among which pubertal development may play a role. Our aim was to study in girls, the relationship of sexual maturation based on menarche with physical activity and sedentary behaviour.

Methods:

Analyses were based on a two-stage random sample of 3,911 10-15-year-old girls included in the 2018 cross-sectional Health Behaviour in School-aged Children survey carried out in French-speaking schools. Menarche, sufficient levels of physical activity (PA) (global PA: at least 60 min. of moderate-to vigorous-intensity PA daily, and vigorous PA: at least 3 times/week), sedentary week time based on all-screen use duration (SWT; categories based on tertiles), and socio-demographic characteristics were self-reported. Multilevel multiple binary (for PA) and multinomial (for SWT) logistic regressions were performed, stratified by age group (≤ 12.5 years vs. >12.5 years).

Results:

Twenty percent of girls aged $\leq$ 12.5 years and 85.0% of girls aged $>$ 12.5 years have had their first period. Within the group aged ≤ 12.5, post-menarcheal girls were more likely to spend long SWT (≥ 8h/day) than pre-menarcheal girls (vs. short SWT (<4h/day): aRRR = 1.74 [1.27-2.37]; NS for moderate SWT (4-7h/day)). Within those aged >12.5, post-menarcheal girls were less likely to engage in sufficient vigorous PA (aOR = 0.76 [0.59-0.98]) than pre-menarcheal girls. Moreover, they were more likely to spend moderate (aRRR = 1.70 [1.19-2.42]) and long SWT (aRRR = 2.74 [1.94-3.88]) than pre-menarcheal girls of same ages. Additional adjustments for age modified the strength of associations.

Conclusions:

Our results suggest that during adolescence, the physiological changes induced by sexual maturation may contribute to the decline in physical activity (in $>$ 12.5 years), and in the increase in sedentary behaviour in girls. Potential confounding by age will be explored further.

Key messages:

- Development of strategies aimed at improving physical activity among adolescent girls should take into account, among other aspects, pubertal development.
- Specific interventions, targeting pubescent girls, should also be developed to reduce screen time in order to prevent its potential negative consequences.

Placing healthy kids meals on the restaurant menu by co-creation between chef-cooks and children

Kris Bevelander

KE Bevelander[1,2], *L Kwakernaak*[2], *E Laset*[2], *G Zeinstra*[3], *G Molleman*[2,3]
[1]Radboud Institute for Health Sciences, Radboud University and Medical Centre, Nijmegen, Netherlands
[2]Behavioural Science Institute, Radboud University, Nijmegen, Netherlands
[3]Public Health, GGD Gelderland-Zuid, Nijmegen, Netherlands
Contact: Kris.Bevelander@radboudumc.nl

Problem:

Eating out is associated with enjoyment, but not healthy meals. The number of families that consume their daily calories from away-from-home foods is increasing. Most restaurants (90%) offer kids meals that are lacking vegetables and are high in calories, sodium and saturated fat. Additionally, families are exposed to many advertisements promoting unhealthy foods and only 3% is aimed at healthy choices.

Description:

The local health authority of the city Nijmegen in the Netherlands started a program (January-June 2019) in collaboration with the local hospital, university, city council, restaurants, primary schools and children's council to promote healthy kids meals in restaurants. Chef-cooks, a dietician and culinary advisor visited the schools they were paired to in their neighborhood to co-create new kids menus. In parallel, students conducted focus groups at schools that could not be visited by the chef-cooks. Information was gathered about which healthy foods children like, and how to present and promote the meals in an attractive way. Next, the children were invited to the restaurants to taste and rate three kids meals created by the input of the children. The winning meals stayed on the restaurant menus for at least a month, while promoting the meals with marketing techniques that were suggested by the children and tested in two experiments: online and in the restaurants.

Results:

During the co-creation lessons at schools, children became more aware of the primarily unhealthy food options in restaurants. Preliminary findings suggest that although most parents would choose unhealthy kids menus in restaurants, healthy meals can be promoted to families by use of characters.

Lessons:

Restaurants are willing to offer and promote healthy kids menus. Co-creation with the target audience and a collaboration between different parties may increase the effect of an environment-level intervention to achieve individual and family-level behavior change.

Key messages:

- Involving children and local parties to increase the availability of healthy kids meals in restaurants and promoting these meals can be an effective way to make eating out a healthy experience.
- A collaboration between different local public and private parties may increase the effect of an environment-level intervention to achieve individual and family-level behavior change.

Study on Children's Health Program and Maternity Health Program, Bulgaria

Stefan Stefanov

S Stefanov[1]
[1]Association Thirst for Life, Sliven, Bulgaria
Contact: dr.stef@abv.bg

Introduction:

The survey was conducted to establish the level access to the Children's Health Program and the Maternal Health Program of the National Health Insurance Fund by marginalized groups. The survey was conducted in the period September-December, 2018 and covered 315 women from Nadezhda neighbourhood (Roma community),Sliven.The methodology used is social accountability and legal empowerment.

Methods:

The survey was conducted through a face-to-face survey. A questionnaire was used with closed and open questions. Consultation with those people was anonymous. We used a ''cold contact' and a ''snowball' method.

Results:

Almost all respondents - 97.7% - have a GP.All (who have the contact of their GP) can easily contact their doctor, although only 7 (2.3%) have the phone number of their GPs. Almost 90% pay part of the cost of treatment, few are cases of full payment or no payment.Quite low - 40.9% - are the rates of visits to the GP in the first month after birth and the appointed (mandatory and due) examinations. Only 45% were examined in the first month after birth by the testimonies of the respondents. It is imperative to take steps to raise the percentage of mothers who visit doctor's office and receive an examinations.74.2% say they adhere to the children's food-hygiene regime. The remaining 20.95% point out the lack of funds and the poor living conditions in the neighborhood (noise, stopping water, etc.) as reasons for not adhering to the regime. While only about 20% claim to have faced discriminatory treatment (just over 30% say they have not experienced it, and nearly half do not respond), there are indicative responses to discriminatory treatment - division in the maternity ward, offensive speech, etc.

Conclusions:

The study achieves its goals - to provide an adequate picture of maternal access to prenatal and pediatric medical care, as well as the difficulties to ensure maximum care for children.

Key messages:

- Roma children are not treated equally under the Children's Health.
- Roma mothers do not have equal access to the Maternity Health Program.

9.S. Mental health inequalities and care

Diabetes care in individuals with severe mental Illnesses in Israel

Ronit Calderon-Margalit

Y Wolff Sagy[1,2], *M Krieger*[1,2], *E Horwitz*[2,5], *O Paltiel*[1,2,3], *S Ravel-Vilk*[2,4], *A Ben-Yehuda*[2,6], *O Manor*[1,2], *R Calderon-Margalit*[1,2]
[1]Braun School of Public Health & Community Medicine, Hebrew University, Jerusalem, Israel
[2]National Program for Quality Indicators in Community Healthc, Israel National Institute for Health Policy Research, Tel Hashomer, Israel
[3]Hematology, Hadassah Medical Center, Jerusalem, Israel
[4]Pediatric Hemato-Oncology, Shaare-Zedek, Jerusalem, Israel
[5]Pharmacy Division, Hadassah Medical Center, Jerusalem, Israel
[6]Internal Medicine, Hadassah Medical Center, Jerusalem, Israel
Contact: ronitcm@gmail.com

Background:

Cardiovascular disease and risk factors are more common in people with severe mental illness (SMI; schizophrenia, schizoaffective disorders, and bi-polar disorders). For instance, diabetes mellitus (DM) prevalence was reported to be 2-3 times higher, with higher incidence and severity of complications. In 2015, following a reform in mental health services in Israel, services were transferred to the responsibility of the health plans, allowing a comprehensive healthcare. We aimed to compare quality of care indicators and intermediate DM outcomes in individuals with SMI compared to the general population.

Methods:

The Israel national program for quality indicators in community healthcare obtains data from electronic medical records from the four health plans, covering the entire civilian population. In 2017, n = 74,226 individuals aged $\geq$18 years had a registered diagnosis of SMI (prevalence 1.37%). DM prevalence, hemoglobin A1c (HbA1c) testing yearly, and DM control in individuals with SMI were compared with the general population.

Results:

DM prevalence in adults with SMI in 2017 was 14.3%, compared with 9.7% among all Israeli adults (RR of 1.5). rates of HbA1c testing and control (HbA1c<7-8%, depending on age and duration of disease) were similar among DM patients with SMI and the general population (testing: 90.1% and 90.9%; Control: 70.8% and 69.7%, SMI and general population, respectively); Similarly, uncontrolled DM (HbA1c>9%) was observed in 10.8% of individuals with SMI and in 10.0% of the general population.

Conclusions:

Along with the expected excess of DM prevalence in individuals with SMI, quality of care DM indicators rates were alike among those with SMI as in the general population, suggesting non-inferior quality of care. This is consistent with results reported by the British national diabetes audit for England and Wales. However, our results are limited by a possible under-registration or diagnosis of SMI in the Israeli population.

Key messages:

- Higher diabetes mellitus prevalence is observed in individuals with severe mental illness.
- Hemoglobin A1c testing and diabetes mellitus control rates are alike in individuals with severe mental illness compared with the general population, suggesting non-inferior quality of care.

Associations between mental illnesses and acute cardiovascular events and cancers in France in 2016

Philippe Tuppin

T Lesuffleur[1], *M Coldefy*[2], *A Rachas*[1], *C Gastaldi-Ménager*[1], *P Tuppin*[1]
[1]Caisse Nationale d'Assurance Maladie, Paris, France
[2]IRDES, Paris, France
Contact: philippe.tuppin@cnamts.fr

Background:

People with a mental illness have higher risks of somatic diseases and higher mortality, but this has been poorly documented in France. We studied the associations between mental illnesses and acute cardiovascular events (ACEs) and cancers in the French national health data system (SNDS).

Methods:

We included all health insurance general scheme beneficiaries $\geq$18 years-of-age in 2016. Mental illnesses (psychotic disorder, neurotic or mood disorder, mental retardation and addictive disorder), ACEs (acute coronary syndrome (ACS), stroke, acute heart failure and pulmonary embolism) and cancers (breast, colorectal, lung and prostate) were identified using algorithms based on long-term disease registry, hospitalization diagnoses and specific drug deliveries. The associations were measured using morbidity ratios standardized by age and gender when appropriate (SMRs).

Results:

ACEs were more frequent in the subjects with a mental illness than in the general population: ACS (SMR: 1.6), stroke (2.3), acute heart failure (1.9), pulmonary embolism (2.4). Similar results were found for each mental illness, except for ACS, which were less frequent in those with a mental retardation (SMR: 0.5) and were not associated with psychotic disorder (SMR: 1.0). Mental illness was also associated with more frequent breast (SMR: 1.3), colorectal (1.3), lung (2.0) and prostate (1.2) cancers, in particular for those with a neurotic or mood disorder (SMRs: 1.3, 1.5, 2.3, 1.2, respectively) and, for lung cancer, those with an addictive disorder (SMR: 2.6).

Conclusions:

Globally, ACEs and cancers were more frequent in patients with a mental illness relative to the general population after standardization by age and gender, which could be related to adverse effects of certain psychotropic drugs or behaviours or risk factors related to the mental illness. Healthcare professionals should be aware of this to more adequately account for the specificities of the patients with a mental illness.

Key messages:

- ACEs and cancers were more frequent in patients with a mental illness relative to the general population after standardization by age and gender.
- Healthcare professionals should be aware of this to more adequately account for the specificities of the patients with a mental illness.

Comorbidity associated with Severe Mental illness (The APNA study)

Ines Aguinaga-Ontoso

I Aguinaga-Ontoso[1,2], *A Brugos-Larumbe*[1,3], *S Guillén-Aguinaga*[1,3]
[1]Department of Health Sciences, Public University of Navarra, Pamplona (Navarra), Spain
[2]Navarra Institute for Health Research, IdiSNA, Pamplona, Spain
[3]Primary Health Care, Navarra Health Service, Pamplona, Spain
Contact: ines.aguinaga@unavarra.es

People with severe mental illness (SMI) that includes bipolar disorder or schizophrenia die on average 10-20 years sooner than the general population. Poor mental health can negatively affect quality of life and life expectancy more so than having multiple physical illnesses. The division between health services treating mental and physical health often means that patients suffering from both physical and mental conditions are at particular risk of poor care. Although more than 50 million people in the EU suffer multiple from more than one chronic disease, it is not well know the comorbidity associated with severe mental illness.

Methods:

The study is a cross-sectional study within the APNA Study (Navarre primary health care prospective cohort) that included 470942 people over 18 years old in Navarre (Spain). Age, sex, chronic diseases diagnosis and SMI) that includes (bipolar disorder or schizophrenia were extracted. Lineal regression models for the number of chronic disease were computed. Logistic regression adjusted by sex and age, was computed for each chronic disease.

Results:

Adjusting by age and sex, people with SMI have 1.47 (95% CI 1.44-1.50) more chronic diseases than people without SMI. Adjusting by age and sex, persons with SMI have a higher prevalence of comorbidity: OR = 13.29 (95% CI = 12.27-14.36). Patients with SMI have a higher prevalence of asthma OR = 1.41 (95% CI 1.21-1.64), COPD OR = 2.30 (95% CI 2.51-3.35), Type 2 DM OR = 1.50 (95% CI 1.31-1.70) hyperthyroidism OR = 1.63 (95% CI 1.26-2.10), Chronic kidney disease OR = 1.,43 (95% IC 1.10-1.88), Obesity OR = 1.68 (95% CI 1.47-1,92) and Hypothyroidism OR 1.63 (95% IC 1.43-1,85).

Conclusions:

Patients with severe mental illness have a higher prevalence of comorbidity than the general population with an OR of 13.29. Health service should screen patient with severe mental illness for chronic diseases due to their high prevalence and mortality.

Key messages:

- Patients with severe mental illness die on average 10-20 years sooner than the general population this could be to a higher prevalence of comorbidity.
- Health services should screen patients with severe mental illness for chronic diseases due to their higher prevalence.

Piloting Sexual Assault Care Centers in Belgium: Who do they reach and what care is offered?

Ines Keygnaert

S Baert[1]Prof dr, K Roelens[2], Dr, C Gilles[3], V Bay[4], Prof dr: I Keygnaert[1]
[1]Department of Public Health and Primary Care, International, Ghent University, Gent, Belgium
[2]Department of Human Structure and Repair, Ghent University Hospital, Gent, Belgium
[3]Department of Gynaecology-Obstetrics, Saint-Pierre University Hospital Brussels, Brussels, Belgium
[4]Nursing Department, Liège University Hospital, Liège, Belgium
Contact: ines.keygnaert@ugent.be

Background:

Care for victims of sexual violence is fragmented in Belgium. Therefore, sexual assault care centers (SACCs) were piloted in three cities from November 2017 onwards. The SACCs offer forensic, medical and acute psychological care through a forensic nurse, while vice inspectors perform an interrogation at the SACC for those wishing to report. The nurse coordinates the follow-up care and a psychologist provides mental health support. A quantitative prospective study was carried out assessing the characteristics of SACC patients, the sexual violence they experienced and the care received, in order to inform the national scale-up of the model.

Methods:

Data on SACC patients was routinely collected in the electronic patient files by the SACC personnel between November 1st 2017 and October 31th 2018. Data was analyzed in SPSS.

Results:

Within the first year SACCs were attended by 930 victims. Mean age was 24,5 years (SD = 12.8), and one third were minors. Eighty-eight percent of victims was female and 67% presented for rape. Fifty-seven percent of the assailants were known to the victim. Thirty-five percent of the victims self-referred to SACC, 41% were referred by the police, and 66% of victims attended services within 72 hours. Respectively 75%, 61%, 47% and 68% of victims received medical care, a forensic examination, psychological care and reported to the police.

Conclusions:

Without big publicity the SACCs received a higher than expected number of victims. Expansion of the collaboration with police and targeted communication strategies should further increase the number of victims receiving appropriate care. Qualitative research assessing the acceptability of the SACC model will further inform the scale-up of the model.

Key messages:

- The quantitative study led to a better understanding of the population using the SACCs.
- The study allowed to improve the training of the staff members, adapt the SACC procedures before scale-up and define targeted service-promotion strategies.

Adolescent's substance use and suicidal thoughts in Tunisia

Jihene Sahli

M El Ghardallou[1], J Sahli[1], M Mellouli[1], M Limam[1], C Zedini[1], L Mezougui[2], A Mtiraoui[1], T Ajmi[1], J Mannai[3]
[1]Department of Familial and Community Medicine, University of Sousse, Faculty of Medicine of Sousse, Research Laboratory ''LR12ES03'', Sousse, Tunisia
[2]Department of Hospital Hygiene, University of Sousse, Faculty of Medicine of Sousse, University Hospital Ibn El Jazzar Kairouan, Sousse, Tunisia
[3]Department of Psychiatry, University of Sousse, Faculty of Medicine of Sousse, University Hospital Ibn El Jazzar Kairouan, Sousse, Tunisia
Contact: dr-jihene19@hotmail.com

Background:

Experimentation with substance use is common during adolescence. Substance use may result in many health-related problems and contribute to adolescent suicidal behavior. We conducted this study to examine the relationship between substance use and suicidal ideation.

Methods:

This is a cross sectional study conducted among a representative sample of 2020 adolescents enrolled in Tunisian secondary schools using a self-administered questionnaire.

Results:

The prevalence of tobacco, alcohol and cannabis use was respectively 3.7% (95% CI [2.87%-4.52%]), 4.4% (95% CI [3.5%-5.29%]) and 0.8% (95% CI [0.40%-1.18%]) Overall, 17.0% (95% CI [15.3%-18.6%]) reported having suicide ideation during the past 12 months. Tobacco (Odds Ratio = 2.61; 95% CI = 1.59–4.29), alcohol (Odds Ratio = 2.77; 95% CI = 1.76–4.36), and cannabis use (Odds Ratio = 4.98; 95% CI = 1.85–13.96) were significantly associated with suicidal thoughts among adolescents ($p < 10\text{-}3$).

Conclusions:

This cross study has shown a significant association between substance use and suicidal ideation. This relationship can be bidirectional and suicidal ideation and substance use may affect each other.

Key messages:

- In his study, the prevalence of substance use was relatively low and was associated with suicidal ideations.
- The reciprocal link between the two problems and their co-occurrence should be taken into account when planning preventive substance use and suicide programs.

Suicide mortality and its income-based inequalities in Korea, 2005-2017

Hee-Yeon Kang

HY Kang[1], J Bahk[2], YH Khang[1,3]
[1]Department of Health Policy and Management, Seoul National University College of Medicine, Seoul, South Korea
[2]Department of Public Health, Keimyung University, Daegu, South Korea
[3]Institute of Health Policy and Management, Seoul National University Medical Research Center, Seoul, South Korea
Contact: hyrose03@gmail.com

Backgrounds:

The suicide mortality rate in Korea has been the highest in the Organization for Economic Co-operation and Development countries between 2003 and 2016. The trends of suicide mortality and its inequalities according to socioeconomic positions provide important information in establishing suicide prevention policies. This study investigated trends in suicide mortality and its income-based inequalities in Korea between 2005 and 2017.

Methods:

Data from 2005-2017 National Health Insurance Database individually linked with cause-of-death data of Statistics Korea were employed. A total of 164,412 suicidal deaths from 574,610,162 subjects aged 10 or over were analyzed. Age-standardized suicide mortality rates were calculated by the calendar year, sex, and income quintiles. The slope index of inequality was calculated as an absolute measure for inequality and relative index of inequality was used as a relative inequality measure.

Results:

The suicide mortality in Korea increased from 29.3 per 100,000 in 2005 to 33.3 in 2011, then decreased to 23.1 in 2017. Suicide mortality rates in men were more than twice as high as the rates in women and the gender gap remained throughout the period. The lower income-level, the higher the suicide mortality rate, especially in men. The absolute inequality in suicide measured by the slope index of inequality has changed as the suicide mortality rate fluctuated, but the relative inequality in suicide has increased since 2012.

Conclusions:

The suicide mortality in Korea has increased due to the global financial crisis and copycat suicide following celebrity suicides in 2008, but it has decreased since the paraquat ban in 2011-12. Despite the recent decline in suicide mortality, the gap between income quintiles did not change meaningfully during the study period. In particular, the magnitude of relative inequality has increased. Progressive national policies should be implemented to reduce suicide mortality and its income gaps.

Key messages:

- Despite the recent decline in suicide mortality in Korea, the income-based inequalities in suicide did not change meaningfully.
- The magnitude of relative inequalities has increased recently.

Social capital and mental health status among the residents of a neighborhood in Istanbul, Turkey

Ilker Kayi

I Kayi[1], *N Ozgulnar*[2]
[1]Public Health Department, Koc University School of Medicine, Istanbul, Turkey
[2]Public Health Department, Istanbul University School of Medicine, Istanbul, Turkey
Contact: ikayi@ku.edu.tr

There has been an increasing policy making and research for social determinants of health and inequalities in health. In such a framework social capital functions as an intermediate factor at the and it is increasingly investigated in health research. Social capital is defined as a resource that individuals may access through membership in a structure of network with certain values and through sharing these resources reciprocally. The objective of this study is to investigate the association between social capital and mental health status among residents of a small neighborhood on Istanbul.

This is a cross-sectional study that has been carried out in Istanbul with individuals of age 18-65 years old. The study sample included 629 individuals selected by a stratified and systematic sampling process. Data was collected via a self-reported questionnaire including items for sociodemographic information, social capital and General Health Questionnaire. We applied Mann-Whitney U and Kruskal-Wallis Tests subsequent to the normality tests of the distribution, and Chi Square Test for the categorical data. Linear and logistic regression models were used for multivariable analysis.

Men constitute 51.7% of the people. Mean age was 40.1 (sd: 12.7). There was a significant association between social capital and being a woman and deprived neighborhood. In addition higher level of mental distress was significantly associated with lower level of neighborhood trust, social support and the higher level of perception that neighbors would take advantage of the participants when they got the chance. However national level trust and sense of people taking advantage of their neighbors were not significantly associated with mental health status.

Social capital measured via trust and social support at the neighborhood level has been a determinant of mental health status. Efforts for decreasing socioeconomic inequalities should also include efforts to promote social capital.

Key messages:

- Social capital measured via trust and social support at the neighborhood level has been a determinant of mental health status.
- Efforts for decreasing socioeconomic inequalities should also include efforts to promote social capital.

A systematic scoping review to approach the construct of gender discrimination

Laura De la Torre

L de la Torre[1], *A Oliver*[3], *X Torres*[2], *MJ Bertran*[1]
[1]Servei de Preventiva i Epidemiologia, Hospital Clínic de Barcelona, Barcelona, Spain
[2]Servei de Psiquiatria i Psicologia Clínica, Hospital Clínic de Barcelona, Barcelona, Spain
[3]Master Salut Pública, Universitat Pompeu Fabra, Barcelona, Spain
Contact: lr.delatorre.prz@gmail.com

Gender discrimination (GD) has been frequently linked to mental health. The heterogeneity of GD definition has led to different assessment methodologies and variation around the analysis of GD. This can affect the study of the association between GD and health outcomes. The main goal of this systematic scoping review is the review of previous studies to operationalize the definition of the GD construct.

Three search strategies were set in Pubmed, CINAHL and PsycINFO. 1st and 2nd search strategies included studies if their main focus was either, the analysis of discrimination perception, triggers of discrimination or the analysis of GD effects and associated factors to its perception. 3rd strategy was focused on the identification of GD questionnaires. The prevalence of GD, factors and consequences associated with GD perception and forms of discrimination were the principal variables collected. Risk of bias was assessed (PROSPERO: CRD42019120719).

A total of 925 studies were obtained and 84 papers included. GD analysis environments were described. 60 questionnaires of discrimination were identified. Prevalence of GD varied between 3.4-67%. Female gender and a younger age were the factors most frequently related to GD. Poorer mental health was the most frequent consequence. Two components of the GD construct were identified: undervaluation (different recognition, opportunities in access, evaluation standards and expectations) and different treatment (verbal abuse and behavior).

GD is measured in several environments and with different methodologies. The two component definition of GD can add order and precision to the measurement, increase response rates and reported GD.

Key messages:

- The heterogeneity in the conception of gender discrimination has led to different ways of assessment and to a great heterogeneity around the analysis of GD perception.
- This operative gender discrimination construct could add order and precision to its measurement, increase response rates and reported GD.

Gender differences in self-reported health - the significance of inequality in domestic work

Carin Staland Nyman

C Staland Nyman[1,2], *G Hensing*[1]
[1]Department of Public Health and Community Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden
[2]School of Health and Welfare, Halmstad University, Halmstad, Sweden
Contact: carin.staland_nyman@hh.se

Background:

Gender difference in health is an important public health issue. Although biological factors contribute, social processes and living conditions create, maintain and exacerbate health differences between women and men. The aim of this study was to examine if lack of equality in domestic work contributes to the explanation of gender differences in self-reported mental well-being, common symptoms and persistent illness.

Methods:

Population based questionnaire data on co-habiting women and men in Sweden, aged 19-64 years (n = 2666), was used. Division of planning and performing domestic work, satisfaction with division of domestic work and equality in partner relationship, were analysed in relation to health outcomes using binary logistic regression analysis with adjustments for age, income, country of birth, occupational class, weekly hours in paid work and number of children.

Results:

Women, compared to men, showed higher odds (OR) for having low mental well-being, OR 1.35 (1.07-1.70), > 7 common symptoms, OR 1.98 (CI 1.59-2.46) and $\geq$ 1 persistent illness, OR 1.25 (CI 1.06-1.47). When equal partner relationship and planning and performing domestic work were included in the regression, the ORs for mental well-being and persistent illness slightly weakened and decreased to non-significance when satisfaction with division of domestic work were analysed, OR 1.14 (0.99-1.44) and OR 1.18 (0.99-1.39) respectively. Corresponding ORs for common symptoms were almost unchanged throughout the analysis.

Conclusions:

Satisfaction with division of domestic work contributed to explanation of gender differences in persistent illness and notably to differences in mental well-being.

Key messages:

- Inequality in domestic work could contribute to explanation of gender difference in health.
- Satisfaction in division of domestic work is of specific relevance in gender difference in mental health.

10.R. Citizens engagement and patient-centered care

Addressing & understanding citizens' perceptions of homelessness: a cross-European study

Owen Taylor

O Taylor[1], S Loubiere[2], A Tinland[3], A Loundou[2], P Auquier[1], HOME EU[4], Jose Ornelas[5]
[1]AMU, Marseille, France
[2]APHM, Marseille, France
[3]MARSS, APHM, Marseille, France
[4]HOME_EU, Consortium, Lisbon, Portugal
[5]APPsyCI, ISPA, Lisbon, Portugal
Contact: owen.taylor@univ-amu.fr

Objective:

Addressing Citizen's perspectives on homelessness is crucial for the design of effective and durable policy responses, and available research in Europe is not yet substantive. We aim to explore citizens' opinion about homelessness and to explain the differences in attitudes within the general population of eight European countries: France, Ireland, Italy, the Netherlands, Poland, Portugal, Spain, and Sweden.

Methods:

A nationally representative telephone survey of European citizens was conducted in 2017. Three domains were investigated: Knowledge, Attitudes, and Practices about homelessness. Based on a multiple correspondence analysis, a generalized linear model for clustered and weighted sample was used to probe the associations between groups with opposing attitudes, adjusted for sociodemographic characteristics.

Results:

The response rate ranged from 30.4% to 33.5% (N = 5,295). Most respondents (57%) had poor knowledge about homelessness. Respondents who thought the government spent too much on homelessness, homeless people should be responsible for housing, people remain homeless by choice, or homelessness keeps capabilities/empowerment intact clustered together (negative attitudes, 30%). Respondents who were willing to pay taxes, welcomed a shelter, or acknowledged homeless people may lack some capabilities (i.e. agreed on discrimination in hiring) made another cluster (positive attitudes, 58%). Older respondents (OR = 0.99; $p = .011$), those living in rural areas (OR = 0.78, $p<.001$), those with a poor level of knowledge about homelessness (OR = 0.68, $p = .007$), and those from France and Poland ($p<.001$) were less likely to report positive attitudes.

Conclusions:

Although it is clear that there is strong support for increased government action and more effective solutions for Europe's growing homelessness crisis, there also remain public opinion barriers rooted in enduring negative perceptions.

Key messages:

- A majority of European citizens reported positive attitudes towards Homelessness.
- There is strong support for increased government action and more effective solutions for Europe's growing homelessness crisis.

Promoting health literacy in seniors through self-reliant groups. Results of the GeWinn intervention

Holger Hassel

H Hassel[1], E Foitzik[1], C Klünder[1], S Langner[1], A Killenberg[1], K Neher[1], M Schimmelpfennig[2], T Zeiler[2], N Ladebeck[2], K Baumgarten[2]
[1]Institute of Applied Health Sciences, Coburg University of Applied Sciences and Arts, Coburg, Germany
[2]University of Applied Sciences Magdeburg-Stendal, Magdeburg, Germany
Contact: iag@hs-coburg.de

Background:

Health literacy (HL) has been demonstrated to be limited among adults aged 65 and over. However, evidence-based HL interventions are lacking. The objective of this study was to develop and test a community-based HL-intervention in the fields of health promotion and self-management of chronic diseases among elderly people.

Methods:

A participatory approach was used to develop and implement a 53-weeks program of self-reliant, peer-moderated groups of people aged 60 and over in 14 municipalities in Germany. HL was intended to be improved by promoting of self-management skills, community participation and media literacy. The intervention's effect on HL was measured by using the HLS-EU-16 questionnaire three times.

Results:

Of 183 older adults who completed the HL questionnaire (mean age 69.8, SD 6.74; 20.1% male), 42.3% had intermediate or low levels of HL. A repeated-measures analysis of variance showed statistically significant effects of time on HL scores ($F1.91 = 16.948$, $p \leq 0.01$, eta squared = 0.085) over the one-year period. HL sub-dimensions showed similar results. 87% of the participants would recommend the intervention to other people.

Conclusions:

The results indicate that the structure of the intervention is appropriate to involve older adults in self-reliant working groups to improve HL. This is supported by the high acceptance of the intervention the participants showed. As part of the sustained implementation of GeWinn, special attention shall be paid to reaching out to and engaging vulnerable groups (e. g. elderly people with low socio-economic status, older men, migrants).

Key messages:

- Self-reliant groups in peer-moderation are effective to engage older adults to improve their HL.
- The intervention improved all HL rates and even doubled the amount of participants with excellent HL.

Changing criteria of access to gamete donation: the views of donors and recipients

Inês Baía

I Baía[1,2], C de Freitas[1,2,3], S Silva[1,2]
[1]EPIUnit-Instituto de Saúde Pública, Universidade do Porto, Porto, Portugal
[2]Departamento de Ciências da Saúde Pública e Forenses e Educação Médica, Faculdade de Medicina, Universidade do Porto, Porto, Portugal
[3]Centro de Investigação e Estudos de Sociologia (CIES-IUL), Instituto Universitário de Lisboa (ISCTE-IUL), Lisbon, Portugal
Contact: ines.baia@ispup.up.pt

Background:

Differences on the use of sexual orientation and marital status as criteria to define access to gamete donation persist in Europe, contributing to the search of cross border reproductive care (CBRC). The lack of international policy and norms on CBRC highlight the need for surveillance to ensure quality and equitable access to reproductive care, namely by assessing donors' and recipients' views. This study aims to analyze the opinion of donors and recipients about the use of marital status and sexual orientation as priority criteria for accessing gamete donation, and its associated factors.

Methods:

Between July 2017 and June 2018, 72 donors and 171 recipients completed a self-report questionnaire at the Portuguese Public Bank of Gametes. Opinion about the use of marital status and sexual orientation as priority criteria was assessed through a 5-point Likert scale of agreement, ranging from ''totally disagree'' to ''totally agree''. Descriptive statistics and multinomial logistic regression were used.

Results:

Most participants disagreed with a priority of access to gamete donation for heterosexual couples (61%) and married women (60%). Participants who agreed with priority to heterosexual couples were more likely to be males (OR = 2.5, CI95% 1.2-5.3) and married or living with a partner (OR = 3.5, CI95% 1.1-10.8). Males (OR = 3.18, CI95% 1.5-6.9) and those with lower white collar (OR = 3.0, CI95% 1.2-7.4) or blue collar occupations (OR = 4.3, CI95% 1.4-13.1) were more likely to agree with priority for married women.

Conclusions:

Donors and recipients agree with equitable access to gamete donation, independently of sexual orientation and marital status. However, a heterosexual marriage hierarchy is particularly observed on male, married/living with a partner, and with lower white or blue collar occupations participants. Policy on reproductive care needs to be especially mindful of equity in access to gamete donation.

Key messages:

- Donors and recipients agree with access to gamete donation independent of sexual orientation and marital status.
- Policy on reproductive care needs to be mindful of equity in access to gamete donation.

'I had no idea what could come'- health care support for AMD in Germany- The patients' view

Anne Their

A Thier[1], C Holmberg[1]
[1]Institute of Social Medicine and Epidemiology, Medical University Brandenburg Theodor Fontane, Brandenburg, Germany
Contact: anne.thier@mhb-fontane.de

Background:

Due to the demographic change visual impairment and blindness in the elderly caused by chronic eye diseases become major public health themes. Age- related macular degeneration (AMD) is one of the most common causes of visual impairment and blindness in older adults above 60 years of age in the western countries, followed by glaucoma and diabetic retinopathy.

Objectives: The purpose of this study is to find out how patients with AMD assess their medical care, tool-based and psychosocial counseling services in Germany.

Methods:

Data was collected by using narrative, semi-structured interviews. A purposive sampling strategy was used to sample the study population with patients with AMD, which is characterized by a variety of different life experiences of the patients. The data analysis followed the principles of grounded theory.

Results:

The interviewed AMD patients were between 72 and 87 years old. Before the patients were diagnosed with AMD, AMD was not known to them and suffering from an unrecoverable disease resulting in blindness, made many of the patients anxious. Patients with AMD complained about missing information about the AMD and its treatment. Tool-related and psychosocial counseling services and their benefits were unknown to most of the patients. Therapy with Anti-VEGF injections gives hope to many patients with neovascular AMD, but at the same time it is associated with a time, psychological and physical strain. The time spent in clinics and practices, the waiting for appointments, the number of examinations and injections, communication problems with the medical staff, information deficits, the injections themselves and their side effects were often severe and nerve-wracking for the elderly.

Conclusions:

New strategies need to be developed to facilitate access to AMD information for patients with AMD, as well as to reduce the time required for medical treatment, e.g. waiting times in clinics and practices.

Key messages:

- Therapy with Anti-VEGF injections gives hope to many patients with neovascular AMD, but at the same time it is associated with a time, psychological and physical strain.
- Patients with AMD complained about missing information about the AMD and its treatment.

Integrating priorities of disadvantaged parents and professionals for community family health

Gerda Wink

G Wink[1,2,4], GAJ Fransen[1,2], MJ Huisman[1,2], SN Boersma[1], WJJ Assendelft[1], MAE Wagemakers[3], J van der Velden[1,2], METC van den Muijsenbergh[1,5]
[1]Department of Primary and Community Care, Radboud University and Medical Centre, Nijmegen, Netherlands
[2]Collaborative Centre PH AMPHI Integral Health Policy, Radboud University and Medical Centre, Nijmegen, Netherlands
[3]Health and Society, Department of Social Sciences, Wageningen University, Wageningen, Netherlands
[4]Health and Communication Research, Wink Works for Health, Wageningen, Netherlands
[5]Centre of Expertise on Health Disparities, Pharos, Utrecht, Netherlands
Contact: Gerda.Wink@radboudumc.nl

Background:

Health inequalities persist, and policymakers, researchers and practitioners seek for effective ways to positively impact the health of disadvantaged people. Researchers point to a multi-component program with an integral design including various perspectives and involving different stakeholders. Few studies address the perspectives on health of disadvantaged people themselves. This study describes what parents in a socially disadvantaged situation and professionals working in that community perceived as 1) priority aspects to improve family health 2) barriers and facilitators for health behaviour changes 3) important health program activities.

Methods:

Design: Community-based participatory action research. 10 parents participated in 6 panel meetings. 46 professionals received 4 panel meetings summaries. 18 parents and 25 professionals responded to questions in (panel) meetings and consultation by phone and e-mail.

Results:

(preliminary) 1) Parents' top priorities for improving health were: less stress related to finances and communication with related organizations, followed by a safe place for kids to meet. Of the program financers' aims (reducing tobacco, alcohol use and overweight) reducing overweight got relatively most support of parents. 2) Parents perceived their family financial situation as barrier to behaviours reducing stress and overweight. 3) Program activities related to reducing stress got more support from parents and professionals than activities related to reducing overweight.

Conclusions:

Insight in the perspectives of disadvantaged parents and professionals resulted in a program plan supported by them, aiming to reduce stress and overweight. Most participating parents and professionals committed themselves to invest time in program activities execution.

Key messages:

- Disadvantaged parents perceived reducing stress related to finances as top priority to improve family health. They perceived family finances as barrier to behaviours reducing stress and overweight.
- Community-based participatory action research with disadvantaged parents and professionals can result in an integrated family health program plan with stakeholder support.

Health promotion with older informal caregivers: a demand-oriented organization of support

Holger Hassel

H Hassel[1], *E Foitzik*[1], *S Langner*[1]
[1]Institute of Applied Health Sciences, Coburg University of Applied Sciences and Arts, Coburg, Germany
Contact: iag@hs-coburg.de

Background:

Older informal caregivers are considered to be a growing, vulnerable group with multiple burdens. Existing support programs are rarely used which indicates a lack in meeting the specific demands of the target group. This study was to examine the need for support and the preferred design of support programs for informal caregivers aged 65 years and older.

Methods:

A mixed-methods approach was used to identify types of current support programs and demands regarding health promotion and self-management of older informal caregivers. Therefore, two systematic literature researches and a qualitative survey of German program providers were performed. Furthermore, 16 focus group discussions (FGD) with older informal caregivers as well as three FGD with disseminators in three German cities were accomplished.

Results:

Most support programs found focus on caregiving instead of health promotion. Most FGD participants preferred: social interaction with health promotion activities, programs thematically focusing on relaxation and physical activity as well as consultation meetings. One of the crucial factors of the utilization of support programs is the guaranteed care of the person who requires it simultaneous to an intervention. In general, it was found that informal caregivers prioritize the health of the person in need of care over their own which indicates low self-awareness.

Conclusions:

Support programs combining social interaction with guided health promotion activities seem to be more attractive to informal caregivers than common programs. Those units should especially focus on the low self-awareness the target group shows. Local network structures need to be strengthened to facilitate the development and utilization of support programs.

Key messages:

- Networks of disseminators could facilitate support programs for informal caregivers.
- These programs should contain social interaction, health promotion activities and ensured care of the person who needs it.

The association between frailty and satisfaction with social contacts in the general older population

Diem Nguyen

D Nguyen[1], *E Braekman*[1], *S Demarest*[1], *J Van der Heyden*[1]
[1]Epidemiology, Sciensano, Brussels, Belgium
Contact: doandiem.nguyen@sciensano.be

Background:

As a result of the demographic evolution, the proportion of older people will continue to increase in the coming decades. Frailty among elderly is one of the important challenges that Europe is facing. From a biomedical, perspective frailty is considered as a clinical syndrome that increases vulnerability. However, the role of social contacts in relation to frailty needs to be investigated. In this study, we assessed the association between frailty and perceived satisfaction with social contacts in a sample of the general older population.

Methods:

This study was conducted on a representative sample of 2364, both institutionalized and non-institutionalized older participants ($\geq$65 years) from the Belgian Health Interview Survey 2018. Frailty was assessed with the instrument used in the Survey of Health Ageing and Retirement in Europe (SHARE) including dimensions of the Fried phenotype: exhaustion, weight loss, muscle strength, weakness and physical activity. The Oslo-3 Social Support Scale (OSS-3) was used to assess perceived quality of social support. Logistic regression was used to determine the association between frailty status and satisfaction with social contacts while controlling for age, gender, region, educational attainment and household composition.

Results:

The prevalence of frailty was 22.8% (95%CI:21.2-24.6). The results showed that elderly who are unsatisfied with their social contacts are more likely to be frail (OR(95%CI):4.65 (2.82-7.66)). In addition, being older $\geq$75 years (OR(95%CI):2.40 (1.68-3.43)), being female (OR(95%CI):2.48 (1.73-3.56)), having a lower education (OR(95%CI):2.57 (1.71-3.87)), living alone (OR(95%CI):1.58 (1.10-2.27)) were associated with frailty.

Conclusions:

Frailty is associated with living alone and being unsatisfied with the social contacts, among older people in Belgium. These findings confirm that the social component should be taken into account in strategies to reduce frailty in the general older population.

Key messages:

- Frailty is associated with living alone and being unsatisfied with the social contacts, among older people in Belgium.
- The social component should be taken into account in strategies to reduce frailty in the general older population.

Organising preventive care and support networks: a need for citizen-centred service delivery

Marleen Fluit

M Fluit[1], *TS Reindersma*[1], *H Broekhuis*[1], *T Bortolotti*[1]
[1]Faculty of Economics and Business, University of Groningen, Groningen, Netherlands
Contact: m.fluit@rug.nl

Background:

There is a growing interest in providing preventive care and support services at a district level (Goodwin, 2014; Kernaghan, 2005) in a citizen-centred way, i.e., accessible, delivered seamlessly, and complying with citizens' needs and capabilities (King & Meyer, 2006). Currently, those citizens who might need it most are not reached and services provided suffer from a lack of coherence (Kodner, 2009; Stange, 2009). This study aims to examine how local authorities organise more accessible and integrated preventive care and support services against reasonable costs at a district level.

Methods:

An exploratory multiple case study approach was adopted. The unit of analysis was the organisation of the preventive care and support delivery process. Policy documents were analysed and 13 semi-structured interviews were conducted with professionals in four Dutch districts.

Results:

Our findings show that three stages of the delivery process should be distinguished, as within each stage a set of specific key design decisions were taken aiming to contribute to easy access and integrated service delivery. These three stages are (a) entrance, (b) exploration of needs and capabilities, and (c) the development of care and support networks. Each case showed a unique constellation of choices on these key decisions, and explicated their motives for organising it in this way. Examples of these key decisions are: the number and location of access points, the number of different professionals involved (indicating the level of (de)coupled process), and the type of professionals involved.

Conclusions:

The results show that different stages and design decisions could be identified across the four cases. These, as well as clear interfaces between the stages, can be regarded as a constellation of choices through which citizen-centred delivery could be enhanced.

Key messages:

- Importance of design decisions in citizen-centred delivery.
- Focus on multi-faceted issue of organising integration within the different stages.

Social inequalities of postpartum depression: the mediating role of social support during pregnancy

Aurélie Nakamura

A Nakamura[1], M Melchior[1], J van der Waerden[1]
[1]Institut Pierre Louis d'Epidémiologie et de Santé Publique, INSERM, Sorbonne Université, Paris, France
Contact: aurelienakamura@gmail.com

Introduction:

A disadvantaged socioeconomic position (SEP), as well as insufficient social support during pregnancy (SSP) increase the probability of subsequent postpartum depression (PPD). The aim of this study was to quantify the part of social inequalities in PPD due to insufficient SSP and in particular assess the impact relative to women's migrant status.

Methods:

The sample included 15,000 women from the nationally representative French ELFE birth cohort study. Depressive symptoms were assessed at two months postpartum by the EPDS. SEP was constructed as a latent factor explaining educational level, occupational grade, employment during pregnancy, household income and financial difficulties. SSP was characterized by informal support (partner perceived support, frequency of quarrels and paternal leave) and formal support (early prenatal psychosocial risk assessment and antenatal classes' attendance). Causal mediation analyses between SEP, dimensions of SSP and PPD were conducted and stratified on migrant status (categorized as native French, first or second generation migrant or immigrant).

Results:

A disadvantaged SEP and a lack of informal SSP during pregnancy were both associated with an increased risk for postpartum depressive symptoms and a disadvantaged SEP was positively associated with lack of SSP. In immigrant women, a larger proportion of social inequalities in PPD could be attributed to lack of SSP, in comparison to native French women (17.5% vs. 8.8%).

Conclusions:

Both disadvantaged SEP and SSP are risk factors for PPD. We found evidence that disadvantaged women's increased risk for PPD can partly be attributed to limited social support.

Key messages:

- PPD in disadvantaged groups, especially in migrant women, could possibly be prevented early in pregnancy by increasing support from partner and larger family.
- Access to social support health care systems directed towards pregnant women remains low for women with a disadvantaged SEP, especially in migrant women.

Multidimensional assessment for patients with multimorbidity in primary care – first practice test

Gerald Gredinger

G Gredinger[1], C Trischak[1], S Reitter-Pfoertner[1]
[1]Competence Center Integrated Care, Vienna, Austria
Contact: gerald.gredinger@wgkk.at

Background:

Multidimensional geriatric assessments are important for early detection of functional deficits, thus contributing to healthy ageing. According to the Austrian Health Care Structure Plan, such bio-psycho-social assessments should be implemented in primary care and build the basis for the care of patients with chronic diseases. Aim of the present study was to test the feasibility of a respective tool at Austrian general practitioners (GP).

Methods:

Overall, 16 GP participated in our practice test and conducted the composed assessment in 185 geriatric patients (39% male, Ø82.6 years, Ø8 diagnoses, 9 medications). Data was analyzed using descriptive statistics (SPSS 26.0).

Results:

In 181 tested patients (98%), the assessment revealed at least 1 relevant functional deficit (Ø4, max. 8). Level of care and number of functional deficits correlated (Spearman: 0.3, $p < 0.01$). Defi-cits were mainly found in mobility (55%: Timed Up and Go-Test >20 sec) and activities of daily liv-ing (86% IADL $\leq$ 15/16 points and 72% Barthel-Index $\leq$ 95/100 points). The average time to com-plete and document the functional tests was 34 minutes (min. 14, max. 61, n = 121). Use of the elec-tronic (vs. paper) documentation resulted in a significant lower time requirement of 9 minutes. Re-garding subsequent interventions, 11 GP suggested 121 interventions in 57/185 patients (30.8%); thereby, pharmacological interventions were preferred.

Conclusions:

We conclude that our tool tool is practicable in primary care as the required time is manageable. Uncovering functional deficits per se did not induce adequate interventions (neither in number nor in quality); therefore, medical algorithms are needed that make precise recommendations for subse-quent diagnosis and/or treatment/care.

Key messages:

- Multidimensional assessments are manageable in primary care and reveal functional deficits.
- Subsequent to the assessment, algorithms are important in order to induce a benefit through inter-ventions.

Inequalities in the participation and outcomes of breast cancer screening programs in Valencia, Spain

Julio Muñoz

J Muñoz-Miguel[1], A Molina-Barceló[5], M Vanaclocha[5], J Ibañez[5,2], P Romeo[3], M Pinto[3], M Hernández[5], M Alcaraz[2], D Salas[5,2,4]
[1]Preventive Medicine Department, Hospital Clínico Universitario Valencia, Valencia, Spain
[2]General Directorate Public Health, Valencian Community, Spain
[3]Universitat de Valencia, Valencia, Spain
[4]CIBER Epidemiología y Salud Pública, Madrid, Spain
[5]Cancer and Public Health, FISABIO - Public Health, Valencia, Spain
Contact: juliomunozmiguel@gmail.com

Background:

Breast cancer remains the most frequent tumour and first cancer related cause of death in the Valencian Community. Despite most of the population being aware of the existence of breast cancer screening programs (BCSP), there are great differences in uptake that are likely attributed to social determinants. The objective of this study, alligning with SDGs 3 and 10, is to assess inequalities in breast cancer screening uptake, diagnosis and treatment delay in the city of Valencia.

Methods:

The population of study included 128 123 women invited to participate in the BCSP in the city of Valencia between 2014 and 2016. Uptake, diagnosis and treatment delay were assessed as outcomes. Covariates included country of origin, education level, size of family unit, risk of vulnerability, age, presence of disability, assigned health department and a social deprivation index. Bivariate analysis and logistic regression models were performed for each independent variable.

Results:

BCSP uptake was of 63,8% with a diagnostic rate of 5,36‰. 76,7% of patients were below the 75th percentile of delay between diagnosis and treatment (52 days). Statistically significant relationships were found between uptake of BCSP and all studied covariates both in the bivariate analysis and regression model. Presence of disability, family unit size, age and health department had a statistically significant relationship with diagnosis in the bivariate analysis, of which only one health department and the social deprivation index's second quintile remained significant in the regression model. No significant relations were found between treatment delay and any of the covariates.

Conclusions:

Strong inequalities in the BCSP have been identified. Influencing factors must be targeted so as to ensure an egalitarian access to BCSP. Given its multifactorial nature, simple analyses must be avoided in the study of inequalities in breast cancer diagnosis. Data on lifestyle may contribute to future models.

Key messages:

- Social determinants continue to have an impact in the uptake of breast cancer screening programs in the city of Valencia.
- The assessment of inequalities in breast cancer diagnosis cannot be approached uniquely through the analysis of social determinants and may Benefit from the inclusion of data on lifestyle choices.

Evaluation of ''Sophia Diabetes'', a diabetic patient support programme, 8 years after its initiation

Claire Leboucher

R Cash[1], *M Cavillon*[2], *C Leboucher*[3], *B Jouaneton*[3], *A Vainchtock*[3], *A Aguadé*[4], *E Gomez*[4]
[1]Les Asclépiades, Ardenais, France
[2]K.Stat Consulting, Paris, France
[3]HEVA, Lyon, France
[4]Cnam, Paris, France
Contact: cleboucher@hevaweb.com

Background:

''Sophia Diabetes'' is a personalized diabetic patient support program piloted by French National Health Insurance, launched experimentally in 10 primary health insurance funds in March 2008, extended in 2010 and then generalized to all of France in 2012-2013. A new evaluation was performed in 2018 to determine long-term (2008-2016) improvement of medical follow-up indicators, impact on morbidity, mortality and healthcare expenditure.

Methods:

A sample of patients (n = 49,016) eligible for the programme in 2008, but also a sub-group of participating patients (n = 17,007), was matched, using propensity score, with controls randomly selected from the SNDS. Difference in difference method was applied for comparisons at each year of follow-up (Ti) while controlling for differences between populations.

Results:

Sophia had a significant positive impact on recommended follow-up indicators, right from the first year. This improvement was maintained for most indicators even if compliance rates remained lower than targets. Sophia Diabetes does not appear to have a major impact on hospitalization rates in either eligible patients or participating patients. However, comparison between participants and controls revealed a less marked increase of hospitalizations for major cardiovascular events at T6 and T7. Compared to their controls, a better use of hospital emergency departments was observed for participants. Ambulatory care expenditure of participants increased more markedly between T4 and T7 (+€105 to €233), related to a better follow-up but in contrast, hospital expenditure increased less markedly during the first year of follow-up (-€139) and the last 2 years (-€360 to -€380).

Conclusions:

For the first time in France, a disease management program has been evaluated over a long period. Globally, Sophia programresults in improved patient follow-up, decreased emergency visits, and a less marked increase of hospitalizations for major cardiovascular events at the end of period.

Key messages:

- First long term evaluation (8 years) of a disease management program in France.
- Sophia diabetes management program shows a positive impact on some follow-up and morbidity indicators.

10.S. Patients, risks and healthcare

Evaluation of the 'sophia' asthma patient management program at two years

Anne-Sophie Aguadé

AS Aguadé[1], *S Guillo*[2], *Y De Rycke*[2], *A Lafourcade*[2], *C Chenivesse*[3], *C Taillé*[4], *G Hejblum*[5,6], *F Tubach*[2,5]
[1]CNAM, Paris, France
[2]Dpt BIOSPIM/Cephepi, INSERM/IPLESP, Paris, France
[3]CHRU, Lille, France
[4]Hôpital Bichat-Claude Bernard, Paris, France
[5]Sorbonne University, Paris, France
[6]INSERM/IPLESP, Paris, France
Contact: anne-sophie.aguade@assurance-maladie.fr

Objectives:

To evaluate the impact of a multi-faceted management support program deployed towards asthma patients by the French Health Insurance since February 2015 in 19 (20%) French pilot areas. **Methods:** The population is composed of subjects aged 18 to 40 years in 2014, with at least 3 asthma medication deliveries in 2012 as well as in 2013 that were identified and followed-up within the SNDS French claims database. A controlled before-and-after design was used for assessing program impact. Unexposed subjects (i.e. living in non-pilot areas) were matched with exposed subjects (i.e. living in pilot areas) on a propensity score. Adherence to controller treatment (inhaled corticoids), measured by the medication refill adherence MRA, was the primary outcome. Secondary outcomes were medications and heathcare use, sick leaves, exacerbations, costs.

Results:

Analysis concerned 29, 746 matched-pairs. With a baseline mean MRA of 40.17% in unexposed subjects, the difference-in-difference was non-significant (0.26%, p = 0.545). However, the program showed a significant impact on the percentage of subjects that moved to a better MRA category or maintained a high adherence (OR = 1.05,p = 0.028). The program had no significant impact on the other secondary outcomes. In planned secondary analyses comparing the 11.5% exposed subjects who adhered to the program to their matched-unexposed subjects, the difference-in-difference showed a program impact on specialist consultations, asthma-related and all medication costs, and total asthma-related costs. However, results on this subpopulation must be examined with caution since the matching procedure couldn't take into account the propensity to adhere.

Conclusions:

Although SOPHIA had no impact on the MRA as a continuous variable, more exposed subjects moved to better adherence categories. The program had an impact on asthma-related costs in the adherents to the program, but this result should be considered with caution.

Key messages:

- Although SOPHIA had no impact on the MRA as a continuous variable, more exposed subjects moved to better adherence categories.

- The program had an impact on asthma-related costs in the adherents to the program, but this result should be considered with caution.

Use of medical care in the 7 years before dementia in the French health insurance database in 2016

Antoine Rachas

A Rachas[1], *A Gallini*[2,3,4], *E Gombault*[2,3,4], *L Carcaillon-Bentata*[5], *V Gardette*[2,3,4], *Ch Gastaldi-Ménager*[1]
[1]Department of Studies on Diseases and Patients, Caisse Nationale d'Assurance Maladie, Paris, France
[2]Department of Epidemiology, University Hospital of Toulouse, Toulouse, France
[3]UMR1027 Epidemiology and Analyses in Public Health, INSERM, Toulouse, France
[4]Department of Epidemiology and Public Health, Université de Toulouse III, Faculty of Medicine, Toulouse, France
[5]Non Communicable Diseases and Trauma Division, Santé Publique France, Saint-Maurice, France
Contact: antoine.rachas@assurance-maladie.fr

Background:

The entry into dementia is a period of growing interest for clinical trials and public health policies. We described the frequency of medical care use in the 7 years prior to the first dementia identification (index date).

Methods:

All French health insurance general scheme beneficiaries aged 65 or more with an incident dementia in 2016 (identified through long-term disease registry, hospitalization diagnoses, or specific drug delivery), were matched with beneficiaries without dementia of same age, gender, area of residence. The annual cumulative incidences (ACI) of visits (GP and specialists, including outpatient hospital visits) and hospitalizations were estimated over 7 years (Y-7 to Y-1 before index date), by age (65-74, 75-84, 85-89, 90+).

Results:

Among 274166 subjects (median age 84, 65% women), the ACI of GP visit was stable and similar between cases and controls, around 95%. The ACI of neurologist, psychiatrist and internist visit and of hospitalization in a psychiatric unit increased in cases, especially in Y-1. They were higher than in controls in the youngest age classes. The ACI of visits to a dermatologist, a rheumatologist, an ophthalmologist, a dentist and for women a gynecologist, were lower in cases than in controls, with an increasing difference in the last years before dementia care. Similar patterns were observed in the oldest exclusively (generally $\geq$85 yo) for pneumologist, cardiologist, nephrologist, and in a lesser extent, endocrinologist visit. The ACI of hospitalizations increased with time in both groups, with a peak in Y-1 in cases. They were higher in cases than in controls in the youngest age classes.

Conclusions:

The increase in hospitalization rate in Y-1 suggests a decline in clinical status leading to the diagnosis or a weakening at the time of entry into dementia. The lesser use of a specialist other than neurologist or psychiatrist suggests a focus of care around dementia, possibly to the detriment of the care of comorbidities.

Key messages:

- As most patients visit their GP at least yearly, specific GPs training could help to make a timely diagnosis of major neurocognitive disorders.
- The lesser use of a specialist other than neurologist or psychiatrist suggests a focus of care around dementia, possibly to the detriment of the care of comorbidities.

Effect of drug compliance on health care costs in newly-diagnosed dementia: a nation-wide analysis

Seung-Taek Oh

[3]Yonsei Hana Psychiatry Clinic and Institute of Mental Health, Goyang, South Korea
[4]Institute of Behavioral Science in Medicine, Yonsei University College of Medicine, Seoul, South Korea
Contact: amikuz@naver.com

Background:

The cost-effectiveness of both cholinesterase inhibitors and memantine by delaying nursing home placement has been supported by numerous studies. The importance of sustained pharmacological treatment in dementia has been relatively less recognized by public health policies compared to early diagnosis. We investigated the effect of the drug (donepezil, rivastigmine, galantamine, and memantine) compliance on the health care costs in newly-diagnosed dementia.

Methods:

National Health Insurance Service (NHIS) database which covers the entire population of South Korea was used for analysis. Health care expenditure of patients newly-diagnosed with dementia in between 2012 and 2014 was investigated for 3 to 5 years. For drug compliance, we used Medication Possession Ratio (MPR) that indicates the percentage of time a patient has access to medication. Multivariate linear regression analysis including generalized estimated equation and gamma distribution was used for statistical analysis.

Results:

We identified 252,594 patients who were both prescribed with cognitive enhancers and newly diagnosed with dementia. When initial MPR increased 20%, total health care costs decreased 8.4% (RR = 0.916, 95%; CI 0.914 to 0.916). Same relationship was shown with medical costs related to dementia, admission to a general hospital, and emergency room visits. When MPR increased 20% compared to the previous year, the total health care costs, admission to a general hospital, emergency room visits, and admission to a nursing hospital decreased.

Conclusions:

This population-based retrospective cohort study provides evidence that patients newly-diagnosed with dementia who showed higher initial drug compliance or maintained anti-dementia drugs (Cholinesterase inhibitors and memantine) would benefit in total health-care costs.

Key messages:

- Public health care policies should not only focus on early diagnosis in dementia, but also recognize the importance of adherence to cognitive enhancers.
- To maximize the positive pharmacoeconomic effect of early diagnosis of dementia, it is important to sustain adequate drug compliance to cognitive enhancers.

Outpatient health care 30 days after hospitalization for heart failure in France

Thomas Lesuffleur

T Lesuffleur[1], *S Feldman*[1], *P Tuppin*[1], *P Constantinou*[1], *V Olié*[2], *Y Jullière*[3]
[1]DEPP, CNAM, Paris, France
[2]SPF, Saint-Maurice, France
[3]Département de Cardiologie, CHU Nancy-Brabois, Vandoeuvre-Les-Nancy, France
Contact: thomas.lesuffleur@assurance-maladie.fr

Background:

Recommendations for heart failure (HF) outpatient follow-up have been published. The SNDS offers the opportunity to confront them to real-life, including geographical disparities. Moreover, estimation variation has to be explored when population excludes institutionalized patients (IP) that have specific healthcare use and refund: rehabilitation (SSR), psychiatric hospitalization (psy), skilled nursing home (EHPAD) which is not usually done.The Purpose is to study outpatient healthcare use variations in France after hospitalization for HF, using SNDS data.

Methods:

The first stay for HF (>0days) in 2015 of patients over 18 yo covered by the general scheme (RG/SLM 88% of population) was considered. Healthcare use 30 days after was compared with (RG/SLM) or without IP (RG/SLM eIP). Regional outpatient care use rates were standardized by age and sex.

Results:

Among 104 984 alive patients 30 days after HF hospitalization (RG/SLM, female 52%, mean age 79 yo), 16% stayed in SSR, 9% in cardiologic SSR, 12% in EHPAD, 0.2% in psy and 75% returning home and not institutionalized (RG/SLM eIP; n = 70367). Among all RG/SLM patients vs RG/SLM eIP (mean age 79 yo vs 78 yo), a cardiologist was seen at least once in 30 days post hospitalization 20% vs 21% (median delay 14 days IQR 7-23 vs 16 IQR 9-24), a general practitioner 69% vs 78% (8 IQR 3-16 vs 7 IQR 3-15), a nurse 58% vs 69% (3 IQR 1-9 vs 2 IQR 1-7). ACE inhibitors were reimbursed at least once for 34% vs 39%, ARBs 14% vs 17%, and diuretics 69% vs 77%. Among RG/SLM eIP patients, departmental disparities were high: cardiologist (3% to 46%), GP (59% to 93%), nurse visit (49% to 82%). Lower rates for GP were found in the center of France but with higher rates for nurse visits.

Conclusions:

We recommend using RG/SLM eIP when studying outpatient healthcare use in the SNDS. Low visit rates and high delays regarding the recommendations point out the need of a multidisciplinary community health care in France.

Key messages:

- Low visit rates and high delays regarding the recommendations point out the need of a multidisciplinary community health care in France.
- We recommend using RG/SLM eIP when studying outpatient healthcare use in the SNDS.

Patient safety culture in Austrian hospitals – A qualitative study

Šehad Draganović

ŠD Draganović[1,2], GO Offermanns[1,2], JB Brandl[3]
[1]Department of Human Resources, Leadership and Organization, University of Klagenfurt, Klagenfurt, Austria
[2]Institute for Hospital Organisation, Karl Landsteiner Society, Vienna, Austria
[3]Department for Developmental and Educational Psychology, University Klagenfurt, Klagenfurt, Austria
Contact: sehad.draganovic@aau.at

Background:

Adverse events in the healthcare system often have severe consequences for the patient and healthcare institutions. Thus, various risk management tools have been recently introduced to 11 Austrian hospitals to increase patient safety. The goal of our study was to test whether the introduced risk management tools actually improved patient safety culture (PSC).

Methods:

An exploratory research approach was used to examine the current status of five aspects from PSC in hospitals. Semi-structured expert interviews with health professionals were conducted (N = 32). The inductive content analysis and technique of content structuring were used to analyze and systemize extensive qualitative data material. Intercoder reliability ($\kappa = .605$) shows satisfactory results.

Results:

The results of the first aspect, Critical Incident Reporting System (CIRS), show that hospitals still have potential for improvement in terms of education of employees, coordination, and communication. The data of the second issue, surgical checklist, shows that the education was insufficient and that these checklists are not handled properly and used only fragmentarily. Concerning the third aspect ''transfer/report'', it can be stated that systematic transfer/reports are widely unknown. Furthermore, the fourth aspect, hand hygiene, lacks a systematic training concept and control of compliance. The fifth aspect, education of risk manager, has brought a number of general benefits (e.g. methodical knowledge) to risk managers.

Conclusions:

The results provide valuable insights into strengths and weaknesses of the implementation of risk management tools and thus highlight opportunities on how to influence PSC through organizational development and change management. Furthermore, this study has taken the first essential step towards the understanding of the effective and efficient development of PSC by providing valuable insights into the underlying mechanisms of non-functioning PSC.

Key messages:

- The study showed where the weakness points in processes of implementing risk management tools are and offered a theoretical solution for the development of a patient safety culture.
- Risk management tools were not equally effective in every controlled aspect. The effective implementation of these tools requires change management as a foundation to develop PSC.

Significant improvement in cancer management in Europe

Marjetka Jelenc

M Jelenc[1], T Albreht[1]
[1]Center for Health Care, National Institute of Public Health, Ljubljana, Slovenia
Contact: marjetka.jelenc@nijz.si

Background:

Cancer management represents one of the most complex disease management segments in health care. Quality National Cancer Control Programmes (NCCPs) play the key role in cancer management in responding to population needs by preventing, detecting and treating cancer only through adequate planning. An effective NCCP represents benefits for patients, citizens, health care providers, health systems and governments. Europe is still characterised by inequalities in cancer control both between and within countries. In response to this challenge, a generic list of evidence-based tools for efficient stewardship and measure of effects of the cancer control will be prepared.

Methods:

A survey on the current state of NCCPs in EU Member States, EEA countries and EU candidate countries and on the presence of some key elements, which NCCPs should include, was conducted in 2018 in the frame of the Joint Action (JA) Innovative Partnership for Action Against Cancer (iPAAC). The completed surveys were analysed; the answers were compared with the report prepared on the basis of the survey carried out in 2011 in the frame of JA EPAAC.

Results:

In total, 33 out of 34 EU Member States, some EEA countries and EU candidate countries completed the survey, the response rate was 97%. Thirty-one out of 33 countries reported that they have a NCCP or another relevant cancer document. Belgium does not have a NCCP, Croatia and Serbia prepared draft versions. The inclusion of patient pathways, quality indicators as well as PROMS in NCCPs is not satisfactory. Only 10 countries included PROMS in their NCCP.

Conclusions:

On the basis of the preliminary results of the survey we conluded that the situation regarding NCCPs in Europe improved in comparison with the situation in 2011. EU countries have mostly adopted a NCCP, plan or strategy as a single or several documents. We aim at developing practical instructions for the successful governance and steering of cancer care in all EU Member States.

Key messages:

- The development of NCCPs represents added value for cancer patients in all EU Member States.
- The inclusion of patient pathways, quality indicators as well as patient reported outcome measures (PROMS) in NCCPs/cancer documents is not satisfactory.

Anaemia under-reporting in a hospital setting in Italy

Francesca Lucaroni

F Lucaroni[1], L Morciano[1], L Morucci[2], A Duggento[1], G Cerone[2], C Ambrosone[2], L Palombi[1]
[1]Department of Biomedicine and Prevention, University Rome Tor Vergata, Rome, Italy
[2]School of Hygiene and Preventive Medicine, University Rome Tor Vergata, Rome, Italy
Contact: f.lucaroni@gmail.com

Background:

Anaemia is a common occurrence in the general population, affecting nearly one in three people worldwide, with peaks in the elderly and those with chronic diseases or micronutrient deficiency.

If recognised, anaemia can often be treated through micronutrient administration, thus an early recognition of the disorder has a significant return in terms of Public Health and of investment.

Methods:

Hospitalisation records from a large sample of ordinary admissions over a year (2016) were retrospectively analysed, in order to assess the impact of hospital stay on anaemia prevalence, defined according to WHO criteria. Prevalence was estimated by both haemoglobin levels and anaemia-related description codes (ICD9CM) at discharge.

Furthermore, the main diagnoses associated with loss of haemoglobin were investigated, using binary logistic regression.

Results:

Over the 15,624 ordinary admissions, we found the prevalence rate of anaemia was 47.2% at hospital admission, increasing to 63.9% at discharge.

During hospital stay, a mean reduction of 0.323 g/dl ($SD \pm 1.39$) haemoglobin was recorded, in particular those with neurological, circulatory, and haematological diseases ($p < 0.001$). By comparing the two diagnostic criteria, a great under-reporting occurred in 85.3% patients with haemoglobin levels predictive for anaemia at hospital discharge.

Conclusions:

Our results highlight the importance of correctly identifying anaemia in the hospital setting as a main Public Health concern. Since haemoglobin loss is recorded during hospital stay, we propose measuring haemoglobin levels not only at admission, but also at discharge, and to enhance proper ICD9CM code inclusion in discharge records. The achievement of both these good practices would have a double effect: to properly inform all the stakeholders and to allow more than half hospital patients, those with haemoglobin levels predictive for anaemia but without specific ICD9CM code at discharge, to be cured in the proper setting.

Key messages:

- Anaemia often remained misidentified during hospitalisation, thus inducing a decrease in mean inpatients haemoglobin levels and a consequent increase of anaemia prevalence at discharge.
- Despite this worsening during hospital stay, a significant underreporting was recorded: 85.3% patients with Hb levels predictive for anaemia at hospital discharge had no specific ICD9CM code.

Preoperative evaluation of patients receiving bariatric surgery: a comprehensive Breton study

Alexandre Rigault

ARB Barataud-Reilhac[1], AR Rigault[1], JB Beauvillain[1], JT Thereaux[2]
[1]Direction Régionale du Service Médical de Bretagne, French National Health Insurance System, Rennes, France
[2]Department of General, Digestive and Metabolic Surgery, La Cavale Blanche University Hospital, Brest, France
Contact: alexandre.rigault@assurance-maladie.fr

Background:

With large demonstrated benefits, volume of bariatric surgery (BS) has increased almost threefold since the late 2000s in France. However, patients seeking for BS must be carefully preoperatively evaluated to reduce risks for late complications (nutritional, neurological and psychiatric). This study aimed to assess preoperative evaluation of BS according to French recommendations.

Methods:

The preoperative evaluation (gastrointestinal, nutritional, cardiovascular and psychiatric) during the year preceding BS was assessed from the French national health insurance database. All patients with a primary BS in Brittany in 2015 were included. For each patient, a score of preoperative evaluation was carried-out (from 0 to 6) and classified as follows: ''complete'' (6), ''incomplete'' (4-5), ''unsatisfactory'' (2-3) or ''poor'' (0-1). Comparisons (chi-square tests) by sex, geographical department, type of institution and health professionals (HP) were made.

Results:

Among the 1,446 patients finally included, 1,195 (83%) were women and the median age was 42 (quartiles: 33-51) years old. Gastric by-pass (66%) and sleeve-gastrectomy (33%) were the most performed procedure. The preoperative evaluation was classified as 'complete' for 501 (35%) patients, 'incomplete' for 647 (45%) patients, 'unsatisfactory' for 238 (17%) patients, and 'poor' for 60 (4%) patients. Better scores were found in 2 departments (Côtes d'Armor and Finistère, $p < 0.001$), in public institutions ($p < 0.001$) and in institutions performing 50 or more acts per year ($p < 0.001$). Heterogeneity according to the HP was also noted in private institutions (median score per HP: 4.5, min-max: 2-6).

Conclusions:

This large regional comprehensive French study confirms that preoperative evaluation before BS is not optimal despite clear French recommendations. Collective reflection should be led to improve the pathway of care of patients seeking BS.

Key messages:

- There are disparities in the performance of BS's preoperative evaluation in Brittany.
- This work suggests that preoperative evaluation for patients seeking for BS should be improved and standardized.

Evaluation of observation of the patients with coronary heart disease after surgical treatment

Vitaliy Koikov

Z Bekbergenova[1,2], G Mauletbayeva[1], A Umbetzhanova[1,2], G Derbissalina[1], V Koikov[2], A Akhmetova[1], N Zemlyanskaya[1], G Alibekova[1]
[1]NCJSC ''Astana Medical University'', Astana, Kazakhstan
[2]RSE on the REM, Astana, Kazakhstan
Contact: vitaliy.koikov@gmail.com

Background:

To reduce mortality from cardiovascular diseases in Kazakhstan, which occupies the leading position, patients are under observation. To evaluate of patients with coronary artery disease who have undergone myocardial revascularization by installing coronary artery stenting or bypass surgery.

Methods:

A retrospective analysis of outpatient medical records of patients.

Results:

Analysis included medical records of 4% patients at the age of 40-49 years, 49%-50-59 years, 22%-60-69 years, 11%-70-79 years, 4% patients older than 80 year. 92% patients were admitted to the hospital with acute coronary syndrome and were urgently operated. Patients with chronic heart failure were operated routinely. 12% patients received surgical treatment twice, including 4% patients routinely. All patients had comorbidities: 63% of people-arterial hypertension, 12%-cardiac arrhythmia, 14%-diabetes. The analysis showed that only 51% of patients were regularly observed in accordance with the standards of the survey during one year of observation. According to the standards the scheduled ECG study of the patients after surgery should be done after 1, 2, 3 and 6 months. In accordance of the standard 23% patients were examined, 3 times a year - 19% patients, 23% people-twice a year. Other functional studies-echocardiography 1 time per year have been studied on 14% people, treadmill test-5% patients. Coagulation monitoring during one year- 46% patients. One of the criteria of proper observation is the number of readmissions. 11% patients were readmitted where 5% of them in the first month after surgery-6% patient with hypertensive crisis, 11%-with an increase of CHF, 2%-with postoperative pleural effusion. 2% patients hospitalized with restenosis after 7 months.

Conclusions:

It should be noted that irregular visits to the doctor questioned the compliance of patients to treatment. Due to the lack of control by medical workers, the patients were not fully examined.

Key messages:

- The continuity of work between hospital doctors and primary care organizations is necessary.
- Patients to improve the favorable prognosis requires regular medication.

Health-related quality of life and risk of hospitalization in a healthy general population

Licia Iacoviello

M Bonaccio[1], A Di Castelnuovo[2], S Costanzo[1], M Persichillo[1], A De Curtis[1], C Cerletti[1], MB Donati[1], G de Gaetano[1], L Iacoviello[1,3]
[1]Epidemiology and Prevention, IRCCS NEUROMED, Pozzilli, Italy
[2]Cardiocentro, Mediterranea, Naples, Italy
[3]Medicine and Surgery, University of Insubria, Varese, Italy
Contact: licia.iacoviello@moli-sani.org

Background:

The association of health-related quality of life (HRQL) with total and cardiovascular (CVD) hospitalization was assessed in a population-based cohort of apparently healthy subjects; several pathways possibly accounting for such associations were also tested.

Methods:

Longitudinal analysis on 16,849 subjects free from CVD and cancer from the Moli-sani Study, Italy (2005-2010). HRQL was performed by the 36-Item Short Form Health Survey including both mental and physical domains. First hospital admissions were recorded by direct linkage with hospital discharge form registry. Hazard ratios (HR) with 95% confidence interval (95%CI) were calculated by multivariable Cox-regression.

Results:

Over a median follow-up of 7.3 y, 6,061 all-cause, 1907 CVD, 431 IHD and 294 stroke hospital admissions were ascertained. The highest quintile of mental HRQL was associated with 23% (95%CI: 17% to 29%), 26% (15% to 36%) and 30% (5% to 48%) lower risk of total, CVD and IHD admissions to hospital, respectively, as compared to the lowest.

Risk estimates for physical health were 0.60 (0.56-0.65 for Q5 vs Q1), 0.57 (0.50-0.65) and 0.73 (0.55-0.97) for total, CVD and IHD hospital admissions, respectively. A downward trend with stroke hospitalizations was found for both mental and physical HRQL. Healthy behaviours explained up to 13% of the association between mental HRQL and IHD risk; inflammatory markers (i.e. C-reactive protein and white blood cell count)) accounted for a significant proportion (34%) of the association of physical HRQL with IHD hospitalizations.

Conclusions:

In a large sample of disease-free subjects, not only physical, but also higher mental HRQL is associated with lower risk of total and CVD hospitalizations.

Key messages:

- HRQL adds meaningful information beyond traditional risk factors to the prediction of hospitalization.
- HRQL assessment may be useful in stratifying hospitalization risk among a general population of healthy adults.

Predictors of in-hospital mortality post hip fracture in Ireland 2013-2017

Helena Ferris

H Ferris[1], L Brent[2], J Martin[1], P Crowley[1], T Coughlan[3]
[1]National Quality Improvement Team, Health Service Executive, Dublin, Ireland
[2]IHFD Audit Manager, National Office of Clinical Audit, Dublin, Ireland
[3]Medical Gerontology, Trinity College Dublin, Dublin, Ireland
Contact: helena.ferris@hse.ie

Background:

Hip fractures are associated with considerable mortality, morbidity and healthcare expenditure. There are approximately 3,500 hip fractures in Ireland per annum with this figure set to increase considerably over the coming years due to the ageing population. Internationally, mortality following hip fracture is approximately 10% at 1 month and 30% at 1 year, with less than half of survivors regaining their preoperative level of function. The authors aimed to identify the determinants of in-hospital mortality post hip fracture in the Republic of Ireland 2013-2017, with specific reference to the Irish Hip Fracture Standards.

Methods:

A secondary analysis of 15,603 patients in the Irish hip fracture database was conducted.

Results:

31% (n = 4,769) were male and 69% (n = 10,807) were female. Mean age for males was 75 years (SD 13.5) and 79 years for females (SD 10.5). The largest proportion of hip fractures occurred in the 80-89 age category, with 72.3% (n = 4,600) of these being female. Median in-hospital mortality was 4.7% (n = 711) (Range 2.7-6.2). Univariate logistic regression revealed 11 statistically significant predictors of in-hospital mortality; however, only 4 remained statistically significant on multivariate analysis [mobilised day of/after surgery (OR 1.46, 95% CI 1.25-1.70, $p < 0.000$), pre-fracture mobility (OR 0.84, 95% CI 0.79-0.89, $p < 0.000$), gender (OR 0.56, 95% CI 0.41-0.76, $p < 0.000$) and age (OR 1.05, 95% CI 1.03-1.06, $p < 0.000$)].

Conclusions:

Older males with poor pre-fracture mobility who were not mobilised the day of/after surgery had the highest risk of in-hospital mortality. The ability to be mobilised on the day of/after surgery is a good composite measure of both patient and organisational factors in hip fracture care. This research supports the inclusion of mobilisation on the day of/after surgery as a new formal best practice standard.

Key messages:

- Patients not mobilised on the day of/after surgery are 46% more likely to die in hospital. In-hospital mortality of 4.7% in Ireland is comparable internationally.
- None of the IHFSs significantly influenced in-hospital mortality after multivariate analysis, but may well affect other outcomes such as ability to return home.

Avoidable hospitalization in Milan's metropolitan area: inequalities and comparison with OECD cities

Benedetta Pongiglione

B Pongiglione[1], A Torbica[1], M Gusmano[2]
[1]Centre for Health and Social Care Management (CERGAS), Bocconi University, Milan, Italy
[2]School of Public Health, Rutgers University, New Brunswick, USA
Contact: benedetta.pongiglione@unibocconi.it

Background:

The largest cities on the world face the unprecedented challenge of meeting the needs of a population that lives longer, has declining birthrates, and is altering the demographic profile on which social welfare programs have long been premised. This work is part of an international project aimed at comparing health and social care systems in megacities worldwide. We study access to healthcare in the metropolitan area of Milan to quantify avoidable hospital care and social inequalities within this world city, and compare Milan with other OECD megacities.

Methods:

Two sources of data are combined: individual-level hospital discharge data to measure hospitalization for ambulatory-care sensitive conditions (ACSC), and municipality-level data collected from the national office for statistics. First, we performed an ecological analysis using a linear model for ACSC hospitalization rates to detect the risk factors in the municipality where the patient resides. Then, to identify both individual and area-level variations in population health, we use multilevel logistic regression model.

Results:

Age-adjusted ACSC hospitalization rates continuously declined from 2005 to 2016, from 16% to 10.7%. Municipality-level risk factors include proportion of residents aged 65+ and proportion of foreigner residents. The individual-level predictors of ACSC hospitalization include being male, being single, having co-morbidities and low education. This association is only modestly attenuated when patient's area-level characteristics are accounted.

Conclusions:

We observed declining trends in ACSC hospitalizations and identified some patient's as well as area-level characteristics related to avoidable hospitalization. Understanding whether ACSC hospitalization has dropped due to improvements in population health and access to healthcare or as part of the overall reduction in hospitalization rates needs to be further explored.

Key messages:

- Effective primary care can reduce hospitalization for preventable and chronic conditions. This work identifies individual and ecological factors related to avoidable hospitalization in urban settings.
- Policies to improve access to healthcare, tackle inequalities and reduce hospitalization costs may be more effective if targeted on individuals considering and the environment in which they live.

Attitudes and behaviours of theology faculty students on organ donation An Eastern City Of Turkey

Ali Ozer

C Tekin[2], *A Gokce*[3], *A Ozer*[1]
[1]Department of Public Health, Inonu University, Medical Faculty, Departmen of Public Health, Malatya, Turkey
[2]Department of Home Care Services, Inonu University,Health Vocational School, Malatya, Turkey
[3]Public Health, Inonu University, Medical Faculty, Malatya, Turkey
Contact: aliozer91@hotmail.com

Background:

Transplantation is the process by which a solid tissue or organ from a living donor or cadaver is transplanted to replace an organ that cannot function properly in the body. Religious beliefs of individuals affect their attitudes and behaviours regarding organ donation. The aim of the study is to determine the knowledge, attitudes, behaviours of Theology Faculty students about organ donation.

Methods:

The study is cross-sectional study which carried out on students in Faculty of Theology.Total number of students was 800 at the time of study. Sample selection was not performed in this study,70% of the population was included. The first part of the questionnaires, which we created as data collection tools, comprised socio-demographic questions, whereas the second part comprised questions, prepared according to the literature that measures the knowledge, attitudes and behaviours on organ donation. Chi-square test was used for statistical analysis.

Results:

0.7% Of the students participating in the study stated that they were organ donors, whereas 56.4% said that they considered organ donation as religiously appropriate behaviour, and 38.6% said that they have not become organ donors before because the subject of organ donation was not brought to their attention previously. A comparison of whether the students viewed organ donation as religiously appropriate behaviour with the students' level of knowledge on organ donation revealed to be 65.8% among students with knowledge on organ donation and 49.5% among students who lacked knowledge on organ donation($p < 0.05$).

Conclusions:

The ratio of organ donors among the participants was 0.7%. Students with knowledge on organ donation also said that they viewed organ donation as religiously appropriate behaviour. Through training activities, the aim should be to increase the level of knowledge and awareness on organ donation of future religious staff and to thereby increase the level of organ donation in the society.

Key messages:

- The ratio of organ donation among Theology Faculty students is low.
- The subject of organ donation should be added to the curriculum of Theology Faculty students.

5. POSTER DISPLAYS
DA Solidarity in health

Analysis of the free caesarean section initiative at the Nabil Choucair Health Center

Mamadou Makhtar Leye

MMM Leye[1], ET Mbengue[2], A Tal Dia[1]
[1]Medecine, Médecine Préventive, Santé Publique, Dakar, Senegal
[2]Ministry of Health, Nabil Choucair Health Center, Dakar, Senegal
Contact: mamadou.leye@yahoo.fr

Introduction:

The initiative for free caesareans was officially launched in December 2004. Our study, with The overall objective of contributing to an evaluation of the impact of this initiative on the operation of the Nabil Choucair Health Center (NCHC) will strengthen its implementation.

Methods:

This is an analytical, cross-sectional, quantitative and qualitative study conducted from September 1 to October 31, 2017 at NCHC. It focused on four target populations: providers, beneficiaries, members of health and co-management committees, and those responsible for maternity and the laboratory. Data entry and analysis were performed with the Excel software and EPI Info version 3.3.2.

Results:

The survey involved a total of 135 beneficiaries, 55 providers, 11 co-management committee members, 2 health committee members, the manager, the laboratory manager, and the chief medical officer of the community. maternity. The average age of the beneficiaries was 29.31 years. The media represented the main source of information with 52%. Despite the free cost of drug expenditure was 40039 FCFA. The average waiting time was 5 hours. The most frequently mentioned problems were: delay in repayment, influx, debt of the structure, abuse of benefits, breakage of reagents and / or drugs. At NCHC 33% of deliveries are by caesarean section. The rate of caesarean section in population has increased from 4% to 8% with free delivery.

Conclusions:

It seems appropriate to make recommendations for the referral of providers on free caesarean section, for the management of cesarean section, for reorganization of services and for the improvement of the quality of reception.

Key messages:

- Caesarean.
- Universal health coverage.

Developing international inter hospital cooperation to reach the SDGs

Helene Rossinot

H Rossinot[1], G Brucker[1], F Veber[1]
[1]Délégation aux Relations Internationales, AP-HP, Paris, France
Contact: helene.rossinot@yahoo.fr

Background:

The current epidemiological transition creates news issues to address (NCD as oncology, cardiovascular, diabetes, road accidents...) and causes an important increase of skills transfer needs in resource-poor/intermediate countries. Hospital cooperation is an efficient way to help the partner country/city adapt and increase their quality of care.

Objectives:

The aims were multiple: set up transfer skills programs, but also understand both obstacles and success factors of such projects over the long term. AP-HP's (Greater Paris University Hospitals) Department of International Relations, has developed 3 year-long projects (financed in majority by public funders) which link one or more hospitals of our group to a southern hospital, on a precise topic. Our multidisciplinary teams then support the local professionals either by training them or assessing their current situation and proposing an action plan.

Results:

Over those last 4 years, we built more than 50 cooperations, most of them being successful and still active today. 20 of our hospitals have been involved in at least one project. In 2018, we were working with more than 30 different countries. We noticed a growing interest both from our teams and new partners, over the years. In 2018, around 150 healthcare professionals from AP-HP took part in at least one mission abroad and more than 3 000 foreign professionals have been trained in various ways (from conferences to technical surgical skill transfer), including about 50 trained on site in Paris. These trainings are intended not only to physicians but also for midwives, nurses and managers.

Conclusions:

Those projects have a good efficiency in a short term. Therefore, the risk of unsustainability is quite important. For the programs to be effective in the long run, there needs to be a collective involvement both from institutions and healthcare teams in the project on both sides.

Key messages:

- European hospitals should develop a strong international cooperation policy.
- AP-HP intends to intensify its work, being an efficient way of contributing to reach both SDG 3 and 9.

Accessibility to oral health care of precarious and non precarious populations in Côte d'Ivoire

Abou Dramane Sangare

Introduction:

The purpose of any health system is to guarantee access to care for the entire population served. However, the socio-economic insecurity situation of people in precarious situations, raises the problem of their access to oral health care considered to be expensive. The objective of this study was to compare the dental status and modalities of oral health care use by people in precarious situations to group of non-precarious population in Abidjan, in Côte d'Ivoire.

Methods:

The cross-sectional study was conducted at the University Hospital Center of Treichville. It concerned all users of the dental office of this hospital. Subjects in precarious situations were identified using a screening tool. Was considered to be in a precarious situation, a person living with less than 1.5 USD/day, having no fixed address, looking for a job, having no health insurance or having difficulties in dealing with medical and pharmaceutical costs. We have identified variables for the modalities of oral health care use and follow-up. The frequencies of these variables were calculated and comparisons were made between subjects in precarious and non- precarious situations using the Chi2 test.

Results:

256 people participated in the study. The tool for identifying precariousness made it possible to distinguish 128 subjects classified in precarious situations and 128 others in non-

precarious situations. The number of missing teeth in people in precarious situations was twice as high as in non-precarious subjects. Renunciation of dental care was more common in the precarious group (46%) than in the non- precarious group (32%). Absenteeism rates at the first two appointments were higher among the precarious (54%) than among the not precarious (46%).

Conclusions:

These results show the need to sensitize the population on the importance of oral health and the establishment of social protection mechanisms to ensure greater accessibility to care for people in precarious situations.

Key messages:

- Improving the oral health of populations, especially vulnerable population groups, requires the establishment of social protection mechanisms to remove the financial barrier to access to care.
- Educating the public about the importance of oral health for overall good health is essential to improving the use of dental care.

Building bridges between community, primary healthcare and academia for solidarity in health

Rabiga Khozhamkul

R Khozhamkul[1], L Kosherbaeva[1], T Izmukhambetov[2], S Tolegenova[3], A Jurgutis[4], B Sydykov[3], K Davletov[1]
[1]School of Public Health, Kazakh National Medical Unviersity, Almaty, Kazakhstan
[2]NGO, Almaty, Kazakhstan
[3]Almaty State Hospital #5, Almaty, Kazakhstan
[4]WHO European Center for PHC, Almaty, Kazakhstan
Contact: r.khozhamkul@kaznmu.kz

Considering Astana declaration on Primary healthcare (PHC) and universal healthcare coverage UN member countries agreed on committing for PHC development. Kazakhstan prepared legal basis for that during ongoing healthcare system reform. Meanwhile, there is no clear mechanism for integration of sectors to address person and community centeredness for health, which has emerged into a need of rethinking engagement between outpatient clinics and their communities. Local NGO "Community health committee" has led the bottom-up initiative in collaboration with Kazakh National Medical University, Outpatient clinic of Almaty State hospital #5, Medeo district mayor's office and WHO European Center for PHC for creation of an integrated plan to strengthen diseases prevention and health promotion at the district. Project aims to strengthen people centeredness of PHC at Medeo district, through equal integration of all stakeholders into every step of decision-making using community based participatory research framework. Project includes development of teamwork in PHC teams' through multi-professional training, development of nurses' competencies for more autonomous work in community, community capacity building and empowerment. After gaining support from all stakeholders, we organized two interactive seminars with community members and PHC teams in order to assess district health needs and build an action plan. Ownership of community members in decision on priority health problem provided community buy-in, high level of engagement and enthusiasm in designing and implementation of the project activities. Voice from empowered community on priority health needs were accounted by local policymakers and led for creation of action plan on identified needs to be implemented in 2019 -2020. One of the main limits of the community engagement is gaining trust and sustainability of the group, we are mitigating it through involvement of academia as an "umbrella".

Key messages:

- Project will create a model for equal partnership in disease prevention and health promotion in Kazakhstan.
- Engaging all key stakeholders based on equal partnership creates sustainable outcomes for health and solidarity.

Critical thinking on strengthening the NGO contribution to improve solidarity in public health

Dilek Aslan

D Aslan[1]
[1]Public Health, Hacettepe University Faculty of Medicine, Sihhiye-Ankara, Turkey
Contact: diaslan.dr@gmail.com

Issue/background:

Public health values transdisciplinary, multidisciplinary, and interdisciplinary perspectives. This background always advocates solidarity which usually finds its positive reflections in the society with the support of many institutional bodies including Non-governmental organization (NGO) movements. which move up solidarity. Globally, NGOs are represented by societies and associations. Turkey is one of the countries which NGO movement is frequent. Turkish NGOs in (public) health may vary on their vision(s) and mission(s). Such variety seems to be "good"; thus, complexity and duplications may occur when a strong systematic ground is not provided. In this paper, a systematic on the functionality of NGOs will be proposed to make the NGO movement more inclusive, accessible, transparent, and auditable in order to support solidarity using the experience of a local case.

Results:

The number of the societies is high in Turkey and they have a wide range of working area including health. Officially they are recorded in the Turkish Ministry of Internal Affairs (MoIA) and can be accessed via the website of the MoIA. There are about 300 000 societies which 116 000 of them are active. The majority of them are founded in big cities. Societies working on health focuses on different areas including professionalism, prevention, rehabilitation, etc. Such varieties may have the potential to create difficulty to follow up their work in a systematic manner.

Lessons:

As NGO/civil society movement is crucial for public health, the proposed steps may contribute to improve/support solidarity on any advocative work on health:

1. To maintain transparency, and auditability
2. To develop methods to prevent duplicative work
3. To develop accessible "common" platforms to share experiences
4. To improve adaptation capacity in the face of new requirements
5. To improve networking among NGOs
6. To improve the global perspective as well as the local one

Key messages:

- Solidarity in public health can be achieved with the help of systematic and powerful NGO/civil society movement.
- Global needs and changes influence civil society dynamics and NGOs should be open to be updated in the face of new requirements.

Improving Health Care Management in Primary Care for Homeless People: A Literature Review

Maeva Jego

M Jego[1,2], J Abcaya[2], C Calvet-montredon[2], S Gentile[1]
[1]EA 3279, CEReSS - Health Services Research and Quality of li, Aix Marseille Université, Marseille, France
[2]Department of General Practice, Aix Marseille Université, Marseille, France
Contact: maeva.jego@gmail.com

Background:

Homeless people have poorer health status than the general population. They need complex care management, because of associated medical troubles (somatic and psychiatric) and social difficulties. However, they face multiple difficulties in accessing primary health care and receive less preventive health care than the general population.

Methods:

We performed a literature review that included articles which described and evaluated primary care programs for homeless people. We searched into the MEDLINE, PsycINFO, COCHRANE library, and Cairn.info databases primary articles published between 1 January 2012 and 15 December 2016. We also performed a grey literature search, and we added relative articles as we read the references of the selected articles. We described the main characteristics of the primary care programs presented in the selected articles. Then we classified these characteristics in main categories, as a descriptive thematic analysis. Secondarily, we synthetized the main results about the evaluation of each intervention or organization.

Results:

Most of the programs presented a team-based approach, multidisciplinary and/or integrated care. They often proposed co-located services between somatic health services, mental health services and social support services. They also tried to answer to the specific needs of homeless people. Some characteristics of these programs were associated with significant positive outcomes: tailored primary care organizations, clinic orientation, multidisciplinary team-based models which included primary care physicians and clinic nurses, integration of social support, and engagement in the community's health.

Conclusions:

Primary health care programs that aimed at taking care of the homeless people should emphasize a multidisciplinary approach and should consider an integrated (mental, somatic and social) care model.

Key messages:

- To improve the health care management of homeless people it seems necessary to priorize multidisciplinary approach, integrated care, involve community health and answer their specific needs.
- It is necessary to evaluate more non-tailored primary care programs that collaborate with tailored structures.

Impact of macro-socioeconomic determinants on perinatal healthcare quality for very preterm infants

Julia Nadine Doetsch

J Doetsch[1,2], *SCS Marques*[1,3], *T Krafft*[2], *H Barros*[1,4]
[1]EPIUnit, Instituto de Saúde Pública da Universidade do Porto (ISPUP), Porto, Portugal
[2]Health, Ethics and Society (HES), Maastricht University, Faculty of Health, Medicine and Life Sciences (FHML), Care and Public Health Research Institute (CAPHRI), Maastricht, Netherlands
[3]Centro em Rede de Investigação em Antropologia (CRIA), Instituto Universitário de Lisboa, Lisbon, Portugal
[4]FMUP, Faculdade de Medicina, Universdade do Porto, Porto, Portugal
Contact: julia.nadine.doetsch@gmail.com

The WHO identified the importance of macro-socioeconomic determinants and the political context as interlinked key factors affecting health equity. The 2008 economic crisis was associated with a significant low-birth-weight increase in Portugal, 2007-2014. The Economic Adjustment Programme (EAP), implemented to economize non-essential health care costs (2011-2014), substantially affected healthcare delivery and occupational environment of Healthcare Professionals (HCPs). This study aims to analyse the impact observed by HCPs of the economic crisis and EAP on equitable quality of perinatal healthcare for very preterm infants in Portugal.

A Qualitative study design with 21 HCPs in clinical settings equally distributed among Portuguese mainland were selected according to their response. Semi-structured interviews were conducted between October 2018-April 2019 until saturation point was achieved. A content analysis was performed using Nvivo2011 software.

Preliminary results on macro-socioeconomic determinants, classified and conceptualized into a three-stage-effect framework, disclosed an interrelation between factors impacting perinatal healthcare quality, according to HCPs. Primary-stage: increase in working hours and patient-ratio per HCPs, cuts in salaries and investment, increasing waiting time and HCPs demotivation. Secondary-stage: burnout, work-absence, time constraints, decreasing quality and consultation availability. Tertiary-stage: HCPs Brain-drain to private sector, double-shifts in public-private sector, increasing inadequacy of transmissivity within sector communication.

The economic crisis and EAP were perceived to have modified equitable perinatal healthcare quality for very preterm infants in Portugal. Increased private-public sector transparency to maximise quality assurance, equal HCP wage distribution to sustain capability, strengthening of social maternity protection strategies to enhance socioeconomic equity in perinatal healthcare, is recommended.

Key messages:

- The added value is the disclosure of an in-depth understanding on the interrelation of macro-socioeconomic determinants and healthcare permitting a distinct representation from quantitative methods.
- The non-linearity between policy response and expected outcomes chiefly complements its comprehension and demonstrates its relevance for further research on assessing effects of austerity measures.

Burnout and quality of life among masseurs with visual impairment - Polish cross-sectional study

Katarzyna Binder-Olibrowska

K Binder[1], *M Wrzesińska*[1], *K Tabała*[1], *A Lipert*[2], *E Miller*[3]
[1]Department of Psychosocial Rehabilitation, Medical University of Lodz, Łódź, Poland
[2]Department of Sports Medicine, Medical University of Lodz, Łódź, Poland
[3]Department of Physical Medicine, Medical University of Lodz, Łódź, Poland
Contact: katarzyna.binder@umed.lodz.pl

Background:

Although there are about 1.3 billion people affected by visual impairment (VI), they do not have equal access to social activities, i.e. they are very often unemployed. The authors hypothesized that being job active plays crucial role for their well-being. The aim of the study was to evaluate the level of burnout and quality of life (QoL) among Polish massage therapists with VI and to determine their relationship with sociodemographic and work-related variables.

Methods:

43 participants aged 28-63, blind or poor-sighted were surveyed with sociodemographic data questionnaire and Polish versions of the Maslach Burnout Inventory-General Survey to measure burnout and World Health Organization Quality of Life Questionnaire (WHOQOL-BREF) to evaluate quality of life.

Results:

Low level of burnout was indicated: 6.79 ± 4.45 in the exhaustion, 7.30 ± 3.43 in cynicism and 23.3 ± 5.44 in professional efficacy. Among domains of QoL the psychological one was the highest (73.6 ± 10.0). Professional efficacy correlated with the social QOL domain ($\rho = 0.306$; $t = 2.056$; $p = 0.046$). Among significant socio-demographic determinants of QOL marital status and working conditions were found. The most general explanation is that job activity gives feeling of self-realization, independence and enhance social functioning which has important meaning for QOL and can be a protective factor for burnout among workers with disability (according to researches among healthy professionals they are at high risk of burnout).

Conclusions:

Job activity is essential for psychosocial rehabilitation in VI. That is why we recommend education tailored to the needs and capabilities of persons with VI to prepare them for work as well as supporting employers in creating jobs opportunities for people with disabilities.

Key messages:

- Job opportunities for people with disabilities mean higher level of psychosocial functioning.
- Workers with disabilities present lower risk of burnout than professionals without impairment.

Youth engagement on health as a political issue

Le Grand Eric

L Eric[1]
[1]Consultant, EHESP, L'Hermitage, France
Contact: ericlegrand35@orange.fr

Background:

In France, young people do not participate in the development of health policy. The latter is built on a representation of the young person who, because of his age, cannot have an opinion and proposals for his health and improve that of others. However, different young people are involved in health actions and propose improvements for the health system and prevention. The communication concerns the 'Re'Pairs Santé', young people who are committed with Unis-Cité, a national association, to developing health actions with other young people.

Methods:

20 'Re'Pairs santé' were interviewed in 3 French cities on their motivation for this engagement. Similarly, 80 young beneficiaries of their actions were met in focus groups to get their perception of Re'Pairs santé.

Results:

The engagement of Re'Pairs santé is part of a dimension of solidarity, and on their experience as young people to change the way adults and public policies are represented. For other young people, if there is an improvement in their health knowledge, half of them are involved in other local associations and/or are involved in changing health within their own structure.

Conclusions:

Health is not a minority issue both in the daily lives of young people and as a potential source of engagement. The Re'Pairs santé investment allows other young people to get involved in other structures. Thus, the social impact is not limited to the transmission of health information but promotes social cohesion and the development of social capital. The place and role of young people in the development of public health policies must be better valued and legitimized in order to better meet their expectations but also to destigmatize a population that has many resources.

Key messages:

- Fostering youth engagement on health.
- Youth should be considered as a resource for health policies.

Health promoting ideas and actions generated by community engagement in an underserved Swedish area

Maria Magnusson

M Magnusson[1,2]*, HB Forslund*[3]*, C Berg*[6]*, K Wretlind*[4]*, M Hallmyr*[1]*, C Hedström*[1]*, LM Vaughn*[5]
[1]Public Health Unit, Angered Hospital, SV Hospital Group, Region Västra Götaland, Sweden
[2]School of Health and Education, University of Skövde, Skövde, Sweden
[3]Institute of Medicine, University of Gothenburg, Gothenburg, Sweden
[4]Public Dental Service Västra Götaland, Region Västra Götaland, University of Malmö, Sweden
[5]Department of Pediatrics, University of Cincinnati College of Medicine, Cincinnati Children's Hospital Medical Center, Cincinnati, USA
[6]Department of Food and Nutrition, and Sport Science, University of Gothenburg, Gothenburg, Sweden
Contact: maria.b.magnusson@vgregion.se

Background:

For an intervention to contribute to decreased health gaps, people living in underserved areas must participate in the research-to-action process during the development of the intervention.

Methods for increased engagement and participation have been developed within the community-based participatory research (CBPR) paradigm. Group Level Assessment (GLA) is a qualitative, participatory methodology that is designed for a large group to generate and evaluate relevant needs and priorities within a lens of action for positive social change. Influence of researchers is tuned down in favour of partnership and impact from the community. Ideally, the process results in participant-driven data and relevant action plans. The aim was to apply GLA to generate reflections on the situation in the community, aligning towards action for change.

Methods:

We applied GLA together with people living in Gårdsten, an underserved Swedish suburb where obesity, caries and other illnesses are prevalent. Residents were recruited by posters and post cards at a community center and by snowball sampling. In total, 47 residents attended at least one of eight GLA sessions held over a five-month time period. The majority were women. Outcomes were reflections, suggestions and actions for change.

Results:

Themes were: resident pride of the area, the importance of communication and of places to meet, a feeling of being abandoned by society, and a desire for more collaboration between schools and parents. Immediate results were a language café and inquiries from the community about information regarding teeth, food and health. When the results were presented for stakeholders in a report and an exhibition, new collaborations were founded and old were refreshed.

Conclusions:

GLA helped residents identify what they thought valuable and relevant concerning health issues and supported them in taking actions to achieve change.

Key messages:

- Participatory processes that directly engage community residents can result in fruitful discussions and actions.
- Methodologies like GLA that support such processes may contribute to closing the health gap.

Public Health and Communication: closing the health gap depending on each other

Maria Magnusson

M Magnusson[1,3]*, C Bertolino*[1]*, M Hallmyr*[1]*, R Landmér*[2]*, J Neselrot*[2]
[1]Public Health Unit, Angered Hospital, SV Hospital Group, Region Västra Götaland, Sweden
[2]Department of Communication, Angered Hospital, SV Hospital Group, Region Västra Götaland, Sweden
[3]School of Health and Education, University of Skövde, Skövde, Sweden
Contact: maria.b.magnusson@vgregion.se

Issue:

At the center of the concept ''Health'' is self efficacy. Communication has potential to increase or decrease individuals/groups conception of themselves as valuable beings. In communities haunted by territorial stigmatization this aspect is crucial. Respectful communication, building on a true belief that competencies and resources dwell in every human being, evoke trust which is an important aspect of public health. Angered Hospital is situated in an area with high prevalence of illness. To allow for residents to exert influence over interventions and programs, the Public Health Unit of the hospital need access to skills not only in the area of public health but also in communication design.

Description of the problem:

The aim was to develop a trusting cooperation between the Public Health and Communication Units in a hospital, building on adherence to the Declaration on Human Rights and on expert knowledge. Focus is on increased health equity. Given barriers of spoken language and different perspectives, how can we set the scene for merging lay and expert knowledge on conditions for healthy habits and prerequisites for change, on individual and structural levels? How can residents be encouraged to seek help when needed? During two years, collaboration developed by intertwining theory and practice in continous discussions on planned and produced objects. Knowledge in communication design and in determinants of health equity, respectively, enriched both parties.

Changes:

A trusting relationship developed, resulting in the objects ''Heroes of Awngaryd''. The Heroes appear in many contexts; transfering knowledge, encouraging residents to use their competencies, inviting them to participate, and guiding to adequate care.

Lessons:

Sharing of the vision of health equity, active embracing of the Declaration of Human Rights and mutual respect for each others expert knowledge form the base for a successful and transparent cooperation between Public Health and Communication.

Key messages:

- In this setting, expert knowledge in both communication design and public health are needed to contribute to increased health equity.
- Common values, trust and specific skills optimize the work.

Understanding place-based public health to reduce inequalities in the context of austerity

Monique Lhussier

M Lhussier[1], *N Forster*[1]
[1]Faculty of Health and Life Sciences, Northumbria University, Newcastle upon Tyne, UK
Contact: monique.lhussier@northumbria.ac.uk

Background:

Ageing populations and increased prevalence of long-term conditions, combined with reduced public funding following the financial crisis mean health needs often outstrip provision. Furthermore, austerity policies across Europe have been associated with a steep rise in health inequalities.

Methods:

A comparative case study design, drawing on realist evaluation, examines the place-based strategies used by five UK Local Authorities (LAs) to maximise resources and reduce health inequalities. LAs were selected based on their implementation of innovative interventions and/or their experience of better or worse than expected trends in reducing health inequalities. Initial programme theories (IPTs) were developed through stakeholder consultation and literature searches, which will be tested and refined using case study data. Data collection methods are tailored to each case study context, but include: documentary analysis; system mapping exercises; and interviews with stakeholders and community members.

Preliminary Results:

Initial programme theories were developed detailing the place-based strategies that are most effective in maximising resources and improving health outcomes, depending on contextual conditions. These theories cover strategies such as income generation schemes to supplement taxation; the introduction of 'disruptive' voices into decision processes; outsourcing and widening skill-sets; reviewing and streamlining resources; and the development of tightly defined targets.

Conclusions:

There is currently a lack of guidance on the optimal allocation of limited resources and effective delivery of services and interventions in contexts of reduced spending. Employing a realist approach has enabled us to move beyond the particularities of local contexts and strategies to produce pragmatic and transferable solutions which can inform the funding decisions of local government.

Key messages:

- LAs have to innovate to balance growing needs with shrinking resources.
- Pragmatic lessons are drawn to inform decision making applicable beyond local contextual specificities.

Hospital ''Outside the walls'' against HIV and other Sexually Transmitted Infections (STIs) in Russia

Déborah Le Nogue

C Bouchet-Mayer[1], *D Le Nogue*[1], *V Henry-Kagan*[1], *M Maric*[1,4], *C Segouin*[2,3], *M Shelly*[1,2]
[1]Pôle, AREMEDIA Association, Paris, France
[2]Centre Gratuit de d'Information, de Dépistage et Diagnostic, University Hospital Saint-Louis-Lariboisière-Fernand Widal (AP-HP), Paris, France
[3]Public Health Department, University Hospital Saint-Louis-Lariboisière-Fernand Widal (AP-HP), Paris, France
[4]University of Reims, Champagne-Ardenne, Reims, France
Contact: deborah.lenogue-mangata@eleve.ehesp.fr

Background:

Though sponsored by UNAIDS support program, Russia struggles to curb its soaring HIV epidemic. French authorities invited Russian leaders of the HIV strategy, medical institutions or civil society in December 2018, to discover the practices of their French peers. A bridging process designed by the Public Health association AREMEDIA and developed in partnership with Fernand-Widal Hospital's testing center, to reach underserved populations, was shown. Merging associative and medical cultures, they created bonds with community associations to efficiently export free prevention, treatments and care for HIV and STIs, ''outside the walls'' of hospital facilities. In March 2019, they were mandated to detect dependable partners to transpose this method in the high-HIV burden Ural region.

Objectives:

Selecting local political leaders, field associations and public health structures, jointly designing a project to adapt AREMEDIA's model in Perm. Developing a training to implement locally outreach program in 2020.

Results:

- Contractual partnership with 4 entities in Perm and educational program.
- Presenting the interventional methodology at Perm University Conference on ''World AIDS day'', 1st December 2019.
- Theoretical and field trainings of Russian stakeholders to outreach sexual health interventions towards key populations, by associative and medical staff from AREMEDIA and the testing center in Paris. Practical support to implement outreach actions in urban areas of Perm from March to December 2020.
- Valorization of scientific results in Saint Petersburg International Conference, July 2020.

Conclusions:

Consensus found on a pilot training and research-action outreach program, approved by authorities. Advancing access to local key populations should foster switching the Russian strategy against HIV towards a comprehensive sexual health promotion paradigm, resulting among others in destigmatization.

Key messages:

- Support local stakeholders to promote equitable management of HIV and overall sexual health.
- Enhance socio-medical interface to reduce the hidden epidemic through reaching HIV key populations.

Giving blood: providing treatment, providing knowledge

Pierre Tiberghien

P Tiberghien[1], *P Gallian*[1,2], *P Morel*[3], *D Bougard*[4], *J Chiaroni*[2], *S Gross*[1], *R Djoudi*[1], *J-C Pagès*[1], *F Toujas*[1]
[1]Etablissement Français du Sang, La Plaine St-Denis, France
[2]Etablissement Français du Sang, Marseille, France
[3]Etablissement Français du Sang, Besançon, France
[4]Etablissement Français du Sang, Montpellier, France
Contact: pierre.tiberghien@efs.sante.fr

Background:

In France, 1,6 million donors contribute 3 million blood donations / year collected and tested by the French public transfusion service (Etablissement Français du Sang - EFS). At each donation, 2 ml plasma of are stored for 3 years for further testing if needed. In addition to providing life-saving blood products, blood donors may also provide knowledge through the sharing of their health data and bioresource collected at time of donation.

Objective:

To describe how blood donors can provide knowledge in addition to blood products.

Results:

Over the last 10 years, blood donors in France have enabled several studies performed by EFS in collaboration with research and reference laboratories as well as public health authorities. A linked assessment of Ab titers (+ clinical history) in donors having given blood before and after the 2009 H1N1 flu epidemic, as well as measles, rubella and hepatitis E virus seroprevalence studies (+ specific health questionnaires) have generated high value epidemiological data. Screening for arboviruses (such as Zika virus) and hepatitis A virus in donors during epidemics have increased knowledge of infectious spread and disease characteristics. Testing of plasma samples collected before variant Creutzfeldt-Jakob disease occurrence in two donors revealed the presence of circulating prion more than 1 year before diagnosis. A project to further take advantage of such a bio resource is underway. Upon occurrence and notification of a disease (or any pre-defined health event) in one of the 1,4 million repeat blood donors, all samples from prior donations would be gathered in a cohort of samples of all donors having notified an identical health event. Such cohorts would provide valuable samples to assess disease-specific biomarkers at pre-symptomatic phases.

Conclusions:

Providing the opportunity to donors to give knowledge in addition to blood can result in production of high value biomedical data. Giving blood, being a public health actor.

Key messages:

- Blood donors may provide knowledge and bioresources in addition to blood products.
- Blood donors in France have enabled several large-scale epidemiological studies.

Disparities in smoking habits in Hungarian Roma and general populations

Szilvia Fiatal

S Fiatal[1,2], *P Pikó*[2,4], *Z Kósa*[3], *J Sándor*[1,2], *R Ádány*[1,2,4]
[1]Department of Preventive Medicine, Faculty of Public Health, University of Debrecen, Debrecen, Hungary
[2]WHO Collaborating Centre on Vulnerability and Health, University of Debrecen, Debrecen, Hungary
[3]Department of Health Visitor Methodology and Public Health, University of Debrecen, Nyíregyháza, Hungary
[4]MTA-DE Public Health Research Group of the HAS, University of Debrecen, Debrecen, Hungary
Contact: fiatal.szilvia@sph.unideb.hu

Background:

Smoking status, dependence and cessation efforts of the disadvantaged Hungarian Roma living in segregated settlements were compared to those of the general population.

Methods:

Data were collected through survey. Each study group consists of 500 randomly drawn subjects, and are representative of the adult (18-64) general and Roma population, living in two counties of North-East Hungary. Questions on smoking from the European Health Interview Survey were used with some modifications. Prevalence data were analysed according to age strata (18-29, 30-44 and 45-64 years) by chi2 test, and were compared to data from 2003 and 2014.

Results:

In Roma the proportion of never smokers is much less compared to the general ones (men:27.27% vs.75%, women:38.6% vs.70.75%, $p < 0.05$). Less Roma reported never smoking in all age compared to 2014, increasing trend can be found in the general population since 2003. Smoking prevalence is higher in Roma in all ages (72.73% vs.20 83%; 68.42% vs.28.42%; 59.02 vs. 32.26%, $p < 0.05$, respectively). Interestingly, the prevalence of Roma men smokers is decreasing by age, in the general population the trend is the opposite. Heavy smoker status is the highest in 30-44 age group of both populations. Increasing trend of heavy smoking can be detected in the Roma, but the opposite holds for general population compared to 2014. Half of the Roma smoke within 5 minutes after wakeup (50% vs. 36.92%, $p < 0.05$), smoke hand-rolled cigarettes (68.91%vs 30.77%, $p < 0.05$), higher proportion of them tried to quit (34.78% vs. 23.38%, $p < 0.05$) but smaller proportion of them obtained advise on how to quit (48.53% vs.59.09%, $p < 0.05$). Initiation starts earlier age among them (men: 15.1 vs.16.6, women: 16.2 vs.18.2, $p < 0.05$).

Conclusions:

Regular smoking (especially heavy) is much higher in the Roma and decreasing by age compared to the general in all age-groups. The 30-44 age group of Roma mean are exclusively heavy smokers but half of the Roma show effort to quit.

Key messages:

- Tailoring cessation programs for Roma men especially those belong to 30-44 age group is a priority to reduce tobacco-related adverse effects.
- Complex public health programmes that taking into account special socio-cultural environment and lower formal education level of the Roma are needed.

Crowdfunding for unmet medical needs: the case of CAR-T and Gofundme

Stefano Guicciardi

F Toscano[1,2], *D Golinelli*[4], *S Guicciardi*[4], *E O'Donnell*[2], *S Rossi*[3], *G Messina*[3], *MP Fantini*[4]
[1]Post Graduate School of Public Health, Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[2]Healthcare Policy and Research, Weill Cornell Medicine, New York, USA
[3]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[4]Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy
Contact: stefanoguicciardi.mail@gmail.com

Background:

Crowdfunding (CF) is the practice of financing a project by raising money from a large number of people. Many patients use online CF platforms to fund medical needs, whether unmet by their healthcare service - therefore to be sought elsewhere -, or when unable to afford them. CAR-T (Chimeric antigen receptor T-cells) is an innovative therapy approved to treat several types of lymphoma and with potential to treat many other cancers. CAR-T is available in most countries through clinical trials only and its diffusion is limited by high costs. Gofundme is a CF platform 'leader in online medical fundraising'. The objective of this study is to shed some light on the phenomenon of CF for CAR-T therapy, describing the campaigns started on Gofundme.

Methods:

We extracted data from CAR-T campaigns started in Europe and publicly available on Gofundme until March 2019. Data related to each campaign has been analyzed and reported through descriptive analyses.

Results:

Since 2017, 26 CAR-T treatment campaigns have been started. Due to the privacy policy of the platform, we were able to retrieve data from only 12 of them; 3 campaigns were closed, thus not disclosing enough data to be included. Nine campaigns were studied: 4 from Italy, 4 from the UK, 1 from Spain. The United States were the main destination. The median campaign goal was 180k€. The number of campaign shares on social media and the percentage of goal raised seemed to be linked.

Conclusions:

CF is unquestionably a good expression of the Internet: it channels empathy towards important causes, providing tangible help. However, when applied to healthcare - especially to experimental treatments -, several questions arise. Patients affected by treatment resistant cancers may be prone trying new treatments to keep the hope alive, even when indication is missing or scientific evidence is lacking. Policymakers should monitor healthcare related CF campaigns, both for equity and safety reasons.

Key messages:
- Policymaker should monitor healthcare related CF campaigns, both for equity and safety reasons.
- Healthcare related crowdfunding campaigns could be interpreted as an indicator of unmet medical needs.

Estimated number of homeless people in Marseille in 2016

Alexandre Daguzan

A Daguzan[1,2], *C Farnarier*[3,4], *S Jaubert*[1], *G Pironti*[5], *S Gentile*[2,6]
[1]LPS EA 849, Aix Marseille Université, Aix en Provence, France
[2]Service d'évaluation Médicale, AP-HM, Hôpital de la Conception, Marseille, France
[3]Projet ASSAb, Hôpital Européen, Marseille, France
[4]LaSSA, Laboratoire de Sciences Sociales Appliquées, Marseille, France
[5]Service de Santé Publique et d'Information Médicale, AP-HM, Hôpital de la Conception, Marseille, France
[6]EA 3279, Aix Marseille Université, Marseille, France
Contact: alexandre.daguzan@ap-hm.fr

Context:
Since 2011, a project in favour of access to rights, access to care and continuity of care for homeless people has been implemented in Marseille (ASSAb project: Access to Care for the Homeless). One of its main lines of action is to improve public knowledge and has led to a census of homeless adults in Marseille in 2016.

Methods:
The methodological approach chosen is based on a survey via homeless services, known as the 'Danish' method, which consists of counting the number of people who have used homeless services at least once over a given period (Brousse, 2005; Marpsat, 2009; FEANTSA, 2016). This approach avoids the difficulties of recording seasonal variations or any other one-off event and controls double counting.

Results:
In 2016, during the year, 14,063 people were at least once homeless in an emergency and accessed a dedicated reception or care facility. Compared to 2011, when 12,648 people were counted, this study reveals an overall increase of 11.2% in this population and a important increase in the number of women (+47%), elderly people (+24%) and minors (+85%).

Conclusions:
Association, institutions and professionals in the field report a greater feeling of increase in the population concerned than shown in this study. The saturation of the reception and support capacities of the structures and the evolution of the situation since 2016 partly explains this representation difference.

Key messages:
- This study informs policy makers and helps them in strategic orientations (Court of Accounts, 2017).
- This study provides input for the thinking and actions of the homeless sector.

DB Migration and health

Factors influencing use of natural environments among immigrant women in Norway

Catherine Lorentzen

C Lorentzen[1], *B Viken*[1]
[1]University of South-Eastern Norway, Borre, Norway
Contact: catherine.lorentzen@usn.no

Background:
Due to a high burden of health challenges among immigrants in Norway, and the documented health benefits of interaction with nature, Norwegian authorities have prioritized the promotion of outdoor recreation among immigrants. Success in this part of public health work presupposes knowledge about factors influencing immigrants' use of nature, which to date is scarce. The present study explores these conditions in a group of immigrant women in Norway.

Methods:
We performed individual interviews with 14 first generation immigrant women aged 27-70 years from Iran (2), Poland (2), Palestine, Afghanistan, Congo, Kenya, Thailand, Russia, Portugal, Latvia, Colombia and Bulgaria. Data were analyzed by qualitative content analysis.

Results:
Multiple and interrelated factors at the individual, relational, cultural/religious, and structural level influenced the interviewees' use of nature. Individual-level conditions included the interviewees' attitudes towards nature and their perceived control over making use of nature. Previous experiences with nature and role model influences shaped attitudes, and knowledge about outdoor life opportunities and appropriate clothing/equipment, and perceived security shaped perceived control. A major relational level barrier was the lack of access to companions for nature outings. A barrier at the cultural/religious level included the discomfort of wearing hijab/all-covering dresses in nature. Main structural level premises for use of nature included available time and economy and access to natural sites.

Conclusions:
This study highlights multiple conditions influencing immigrant women in Norway's use of nature. Public health actors should be aware of and take into account this knowledge.

Key messages:
- Factors influencing immigrant women in Norway's use of nature are to be found at different levels of influence.
- Strategies for increasing immigrants' use of nature should be based on existing knowledge about influencing factors.

Perceived risks and barriers to care for international migrants in transit through Mexico

Silvana Larrea

S Larrea[1], *R Leyva-Flores*[1], *N Guarneros-Soto*[1], *C Infante-Xibille*[1]
[1]National Institute of Public Health, Cuernavaca, Mexico
Contact: chivislarrea@gmail.com

Background:
Mexico has implemented policies seeking to reduce barriers to care for migrants in transit; however, it is estimated that only 3% of migrants use public health services when needed. The main purpose of this study was to identify the barriers to access public health services faced by migrants in transit through Mexico.

Methods:
Under the human security perspective, in 2018, a qualitative study was carried out in Mexican communities with high migrant mobility. 34 semi-structured interviews were conducted with migrants in transit, and personnel from public health services and migrant shelters (NGOs). Values and meanings related to risks, health problems, barriers to care, experiences of health services utilization, and opinions on facilitating elements to diminish these barriers were identified.

Results:
Migrants in transit through Mexico face risks that affect all dimensions of human security. Perceived anti-migratory and discriminative attitudes during the journey were constantly mentioned in the interviews. Barriers to care were found in the four stages of health care access, classified according to the Tanahashi framework, with the majority related to accessibility and acceptability. The following facilitating elements were also identified: political willingness of local government, knowledge and talent management of health personnel, and strategies implemented for adapting local health care services to migrants.

Conclusions:

Social and political conditions in Mexico disrupt any effort to reduce social risks and barriers to care for migrants in transit. Non-governmental actors are key players for facilitating interactions between migrants and local governmental health care institutions. However, the general anti-migratory context negatively affects access to health care and influence the perspectives of migrants, NGOs, and health personnel.

Key messages:

- The predominant perceived barriers to care are in counterpoint to local governmental pro-migrant rights perspectives.
- NGOs are key actors to promote access to public health care services.

Migrants in Austria and their understanding of mental health issues

Marion Weigl

M Weigl[1], *S Gaiswinkler*[1], *H Wolf*[2], *H Haider*[2]
[1]Austrian Public Health Institute (Gesundheit Oesterreich GmbH), Vienna, Austria
[2]Women's Health Center FEM Süd, Vienna, Austria
Contact: marion.weigl@goeg.at

Psychosocial needs are common among migrants but their use of mental health services is not. Little is known about the understanding of mental health issues by migrants and their perception of mental health services. The study aims to provide a basis for further developments of the mental health system to contribute to health equity in the long term.

Qualitative research: literature review, semi-structured interviews and focus groups. 54 migrants from Afghanistan, Somalia, arabic-speaking countries and Turkey and 16 experts were involved. Access was gained through cooperating with an institution offering various health services in different languages and well-known by migrant communities. Migrants from Turkey with long residence in Austria and linked to psychosocial services were chosen as reference group. There are many similarities among socio-economically disadvantaged people in terms of their understanding of mental health and their willingness to seek and accept support. However, differences can also be observed which are related to country of origin or gender, but also to acculturation status, current life situation or previous experiences within the home or the receiving country. The Turkish reference group shows, that mental health issues are given higher priority in the course of time. To quicken this process, targeted measures for the promotion of health literacy are decisive, but also integration possibilities and the social climate. With a wide range of access and psychosocial support options, attitudes like openness, impartiality and flexibility among health professionals, it is possible to reach migrants with psychosocial needs.

A stronger exchange on how people with a migration background and psychosocial needs are perceived and reached is needed. But also activities to increase the diversity of support services and to carry information about mental health issues as well as the existing services into the migrant communities

Key messages:

- Specific activities can improve the knowledge about mental health issues within migrant communities.
- A wide range of access and psychosocial support services is needed to address the diversity.

Advocating migrant and minority health in Bulgaria through an innovative education subject

Mariela Kamburova

M Kamburova[1]
[1]Medical University of Pleven, Pleven, Bulgaria
Contact: mariela_kamburova@yahoo.com

Introduction:

Migrants and ethnic minorities often face serious inequities concerning their access to good quality health services. The Statement by the European Public Health Association on migration, ethnicity and health addresses the need of supporting public health policy makers by providing education courses.

The objectives of the teaching course ‘‘Migrant and minority health’’, established in Medical University-Pleven in Bulgaria as optional additional subject, is to extend the specific knowledge of students (bachelors and masters of public health) and to develop competencies and skills of future public health practitioners and policy makers.

Results:

The unique for Bulgaria course consists of 15 academic hours of the curriculum and ends with an electronically based test. Teaching methods include lectures, seminars and individual practical assignment and stresses on practice rather than theory. The training advocates migrant and minority health by presenting: the most important migrant's social and health problems; impact of migrants' health status on public health; the organization of healthcare in the recipient countries of migrants. The lecture course provides information for the main challenges facing healthcare professionals and the health system regarding the health of the migrants and main minorities groups, in particular the Roma as a predominantly ethnic minority in Bulgaria and Europe. The result of exam until now is good in 42.8% of students, very good in 14.2% and excellent in 42.8%. The curse enable public health professionals to acquire knowledge regarding to the international situation, critical assessment skills and the ability to implement appropriate strategies to address specific health problems.

Conclusions:

The training meets the needs of in-depth knowledge of public health specialists in relation to the medical and social problems of migrants and minorities in Bulgaria. The positive experience gives ground to include it as part of basic curricula.

Key messages:

- The subject ‘‘Migrant and minority health’’ enhances student's competencies as public health practitioners. Knowledge and skills are relevant to the EUPHA Statement on migration, ethnicity and health.
- By the subject ‘‘Migrant and minority health’’ public health practitioners may work to establish friendly health system with good quality of health services for migrants and Roma population in Bulgaria.

Health, wellbeing and access to care of undocumented migrants in Geneva, Switzerland

Yves Jackson

Y Jackson[1], *L Consoli*[2], *A Duvoisin*[2], *J Fakhoury*[2], *G Ferro-Luzzi*[3,4], *C Burton-Jeangros*[5]
[1]Division of Primary Care Medicine, Geneva University Hospitals, Geneva, Switzerland
[2]CIGEV-LIVES, University of Geneva, Geneva, Switzerland
[3]Geneva School of Economics and Management, University of Geneva, Geneva, Switzerland
[4]Geneva School of Business Administration, HES-SO, University of Applied Sciences and Arts Western Switzerland, Geneva, Switzerland
[5]Institute of Sociological Research, University of Geneva, Geneva, Switzerland
Contact: yves.jackson@hcuge.ch

Background:

Switzerland hosts 50'000 to 100'000 undocumented migrants but hardly any evidence exist about their health and wellbeing. A pilot regularization policy took place in Geneva (2017-2018).

Methods:

Parchemins is a mixed-methods prospective study assessing the impact of legal status regularization on undocumented migrants' health and wellbeing. The quantitative data collection uses yearly face-to-face health questionnaire. Wellbeing is measured by self-reported satisfaction with life on a 10-point Likert scale. We present the results of the first wave of data collection conducted before regularization.

Results:

Participants were mainly women (71.9%) from Latin America (63.2%), aged 44.2 (SD 10.4) years, with secondary or higher education (77.3%), living in Geneva with a partner (47.6%) and minor children (22.3%) for an average of 11.8 (SD 5.4) years. While 82.2% reported good to excellent health, 54% presented overweight or obesity and 21% suffered 3 or more chronic conditions. Self-reported prevalence of hypertension, hypercholesterolemia and diabetes were 17.6%, 7.6% and 4.9%, respectively. Screening for depression and anxiety using PHQ-9 and GAD-7 scales was positive in 45.2% and 35.9% of participants. Only 29.9% had a health insurance. In the previous year, 74.8% had at least one medical consultation and 30.4% consulted in emergency but 27% had renounced to seek care for economic reasons. Overall, 97.3% were exposed to health hazards at the workplace and 5.9% suffered an accident leading to work interruption in the last 6 months. Overall, life satisfaction level amounted to 7.4 (SD 2.2) out of 10.

Conclusions:

The baseline results show a contrast between good self-reported health and fair wellbeing with frequent comorbid health conditions notably of mental origin, exposure to occupational hazards and economic limitations in the ability to respond to one's health care needs. Next study waves will shade light on the public health and clinical impact of regularization.

Key messages:

- Legal status may act as a key determinant of health therefore regularization is likely to produce significant health effects.
- Undocumented migrants good wellbeing and self-reported health contrasts with high morbidity notably of mental origin.

Adequate utilisation of emergency services in Germany: a differential by migration background?

Odile Sauzet

O Sauzet[1], M David[2], B Naghavi[2], T Borde[3], J Sehouli[2], O Razum[1]
[1]School of Public Health, Bielefeld University, Bielefeld, Germany
[2]Clinic for Gynaecology, Charité, Berlin, Germany
[3]Alice Salomon Hochschule, Berlin, Germany
Contact: odile.sauzet@uni-bielefeld.de

Background:

The role of emergency services (ES) is to provide a round-the-clock acute care. In recent years, inadequate use of emergency services has been internationally thematised because of overcrowding and the cost associated. There is only limited evidence regarding the pattern of utilisation of ES by populations with a migration background.

Methods:

Consecutive patients visiting three ES in Berlin from July 2017 to July 2018, and who fulfilled inclusion criteria such as being conscious, were recruited into the study. A questionnaire covered medical conditions, reasons to visit the ES, and socio-economic factors. A criterion for the adequacy of utilisation was developed using a sub-sample of patients with information provided by physicians. Differences between migrants (1st generation), their offspring (2nd generation), and non-migrants were evaluated using logistic regression.

Results:

2 327 patients were included, 901 had a migration background. The utilisation was adequate if the patient was admitted to hospital and/or if all three following criterion were fulfilled: reported to have been advised by a physician to visit the ES; reported strong pain; and reported a high perceived urgency (both ≥ 7 on a scale from 0 to 10). Adjusting for gender, age, condition and number of recent visits to ES, 1st generation migrants had a significantly higher chance than non-migrants to have an inadequate utilisation of services (OR 1.30; 95% CI [1.01; 1.68]). For 2nd generation persons, this was not statistically significant.

Conclusions:

First generation migrants have a higher chance of inadequate ES use compared to non-migrants. A similar study 20 years ago had similar findings. This implies that existing information leaflets on ES addressing specific population groups are not sufficient to improve adequacy of use. Structural changes in the healthcare system as well as improved methods of communication respecting the needs of diverse subgroups of patients need to be considered.

Key messages:

- Existing information leaflets on emergency services addressing specific population groups are not sufficient to improve adequacy of use.
- Structural changes in the healthcare system as well as improved methods of communication respecting the needs of diverse subgroups of patients need to be considered.

Support for unaccompanied children and youth - Results from a systematic literature review

Henry Ascher

H Ascher[1,2,3], Å Backlund[4], P Östlund[5]
[1]School of Public Health, University of Gothenburg, EPSO, Gothenburg, Sweden
[2]Child Refugee Team, Angered Hospital, Gothenburg, Sweden
[3]Research Department, Angered Hospital, Gothenburg, Sweden
[4]Department of Social Work, Stockholm University, Stockholm, Sweden
[5]Swedish Agency for Health Technology Assessment and Assessment of Social Services (SBU), Stockholm, Sweden
Contact: henry.ascher@gu.se

Background:

A systematic literature review about unaccompanied minors was done with the following focus:

- scientifically documented effects of support
- experiences of unaccompanied children and youth about positive and negative factors

Methods:

2 210 abstracts were examined. Assessment of relevance and quality and the analysis were done according to SBU standard.

Results:

No controlled study on effects were fulfilling the inclusion criteria. However, 29 articles with qualitative design were included. Seven overall themes were identified:

- Security and control: a basic requirement
- The new country: both opportunities and difficulties
- Managing difficulties: a balance between different strategies
- Everyday environments: supportive relationships as well as influence in housing and access to schools and activities are important
- Relationships: support and guidance from adults is important, contact with peers important, but also difficult
- Social services and health and medical care: varying views on and experiences of support and needs
- Identity and affiliation: getting together the past, the present and the future.

The seven themes could be grouped in three overarching levels:

1. Basic living conditions and survival
2. Difficulties and opportunities in everyday life
3. Weighting of bringing together existence on an overall plan

Conclusions:

To our knowledge, this is the largest literature review about support for unaccompanied children and youth. In the absence of controlled effect studies, it is particularly important to pay attention to unaccompanied children and youths own experiences when providing guidance for how societýs support for this heterogeneous group can be designed, in accordance with their rights in the Convention on the Rights of the Child. The results of the review are compared to common policies in handling unaccompanied children and youth.

Key messages:

- Unaccompanied children have commonly experienced trauma and loss. A lack of basic security has a pronounced effect on the ability to cope with daily issues and difficulties as well as with the future.
- Unaccompanied children and youth have a great need for adult support and guidance.

Parent emigration and physical health of children left behind: systematic review of the literature

Justina Racaite

J Racaite[1], *G Surkiene*[1], *M Jakubauskiene*[1], *R Sketerskiene*[1], *L Wulkau*[2]
[1]Institute of Health Sciences, Department of Public Health, Vilnius University Faculty of Medicine, Vilnius, Lithuania
[2]Faculty of Social Work and Health, University of Applied Sciences Emden/Leer, Emden, Germany
Contact: justina.racaite@mf.vu.lt

Background:

Children left behind (CLB) are those, who have been left behind at their original residence while one or both parents migrate to other places for work. The aim of this study was to systematically review studies where the physical health consequences for CLB were analysed.

Methods:

We searched the Web of Science, PubMed, Academic Search Complete, PsycINFO and Cochrane databases. We included studies reporting physical health outcomes of children affected by parent migration.

Results:

We selected 35 studies from a total of 2191. The results reveal that, overall, the absence of one or both parents is related to poorer child health - the nutrition of CLB is not healthy or balanced and is insufficient, leading to higher rates of anaemia and poor growth indicators of affected children. Boys left by parents are smaller than boys who were never left behind. CLB face lower underweight or stunted growth risks due to the additional income from remittances which ensures sufficient food for the household, this can also lead, however, to overweight and obesity. Unhealthy lifestyle behaviours such as smoking, alcohol, food preferences, lower physical activity and higher risk of injuries were more prevalent among CLB. CLB were more likely not to have completed the recommended vaccination programme than those living with their parents. Opinions vary on how emigration of parents affects children's well-being and quality of life. CLB had higher probabilities of higher well-being than children living in non-migrant households. However, health-related quality of life (HRQoL) of CLB scored significantly lower than HRQoL of non-left-behind children.

Conclusions:

The migration of parents has negative impacts on the child's physical health, however it can also have positive impacts on children's well-being when basic needs for sufficient nutrition are not satisfied in the home countries. Public health interventions should be taken to ensure the health of the CLB population.

Key messages:

- This is the first systematic review on the physical health of CLB.
- The well-being of CLB is poorer and they are at risk of health problems, such as insufficient and/or unbalanced diet, unhealthy behaviours and incomplete vaccination status.

Non-communicable diseases among refugees claimants in Greek refugee camps—are their care needs met?

Signe Smith Jervelund

SS Jervelund[1], *O Nordheim*[2], *T Stathopoulou*[3], *TA Eikemo*[2]
[1]Department of Public Health, University of Copenhagen, Copenhagen, Denmark
[2]Department of Department of Sociology and Political Science, Norwegian University of Science and Technology, Trondheim, Norway
[3]National Centre for Social Research, Athens, Greece
Contact: signesmith@gmail.com

Background:

Little is known about the prevalence of non-communicable diseases (NCDs) among newly arrived refugees in Europe and whether their medical needs are met. The objective of this study was to investigate patterns of NCDs as refugee claimants migrate, whether refugee claimants experience unmet health-care needs before, during and after flight when living in Greek refugee camps and to elucidate sociodemographic determinants for unmet medical care needs in the Greek refugee camps.

Methods:

Survey data collected in 2016 among 267 newly arrived adult asylum-seekers staying at six refugee camps in Greece was used. The survey was available in English, Arabic and Farsi. We inspected frequency distributions of NCDs and unmet medical care needs, and using multiple logistic regression analysis, we estimated determinants for unmet medical needs in Greece.

Results:

The majority had a good or fair self-reported health; yet, 17.1% suffered from 1 NCD, while 42.1% suffered from 2 or more NCDs. The most prevalent reported NCDs in Greece were: back or neck pain (26.6%) and severe headache (24.7%). The prevalence of most NCDs in the migration phases followed a U- or J-shaped pattern: decreased during migration and increased after migration to Greece. Unmet medical care needs were reported by 41.3% with one NCD after arrival in Greece. Compared with young adults, adults aged 51+ years were in increased risk of reporting unmet medical needs in Greece [odds ratio = 7.59; p = 0.015].

Conclusions:

The high number of persons who report NCDs underscore the need for availability of diagnostic tools and agents to ensure that the refugee claimants receive the right healthcare assistance. Tools and guidelines to provide continuity of NCD care when people migrate are likewise important. Many European countries that receive this group of refugees should take the disease patterns, including multi-morbidity, into consideration when planning for health reception and the organization of healthcare.

Key messages:

- The prevalence of NCDs among refugee claimants decreased during migration and increased after migration to Greece.
- Unmet medical care needs were reported by 41.3% with one NCD after arrival in Greece.

A partnership between a local public health unit and schools to end female genital mutilation

Maria Margarida Paixão

M Paixão[1], *A Carmona*[1], *H Capelão*[1], *A Silva*[1]
[1]Public Health Unit António Luz Amadora, Regional Health Administration of Lisbon and Tagus Valley, Damaia, Lisbon, Portugal
Contact: margaridacpaixao@gmail.com

Female genital mutilation (FGM) is a violation of human rights and has immediate and long-term health impacts. Our public health unit is in Amadora, one of the regions in Portugal with the highest prevalence of FGM in immigrant communities.

Recognising the importance of education and of early-life interventions in changing beliefs, we partnered with local schools, a non-governmental organisation and child protection services. We developed a book with information and resources for teachers and created a training package for school professionals. This comprehensive school intervention focused on two aspects. First, it focused on prevention, as we trained school professionals, provided risk score indicators and defined actions to take. Second, in health promotion as we compiled ideas and resources on how to approach this subject in classes while debating sexual health, gender inequality, human rights and cultural heritages.

From November 2018 to February 2019 we collected inputs by all partners and tested the instruments in a pilot school with a mixed-methods approach through questionnaires and a focus group.

The book was distributed to all schools in Amadora, to other public health units and institutions. The preliminary evaluation was done by a questionnaire where 72.7% of the respondents found it useful and addressing the key topics and 54.5% found it detailed enough. These results are preliminary, with further evaluation planned for September 2019 and June 2020 to understand both the experience and needs of teachers after implementing the project.

This project has led to schools showing interest in developing closer cooperation in this and in other health topics.

To our knowledge, this is the first school intervention by a public health team focusing on FGM in Portugal. Other countries have materials on FGM for teachers, however we believe our intervention was the first tailored to a local community and in close collaboration with local schools and institutions.

Key messages:

- There is potential for a closer collaboration with schools to try to end female genital mutilation and to address other health topics.
- Local public health units should establish and mobilise local networks of institutions and community partners to tackle complex public health problems.

Culturally sensitive diabetes education supporting ethnic minorities with type 2 diabetes

Nana Folmann Hempler

NF Hempler[1]*, DH Laursen*[2]*, C Glümer*[2,3]
[1]Diabetes Management Research, Steno Diabetes Center Copenhagen, Gentofte, Denmark
[2]Center for Diabetes, Copenhagen Municipality, Copenhagen, Denmark
[3]Department of Health Science and Technology, Aalborg University, Aalborg, Denmark
Contact: nana.folmann.hempler@regionh.dk

Background:

Ethnic minorities of non-Western origin are at higher risk of type 2 diabetes and diabetes complications, compared to the general population. Diabetes education programmes are essential to support people with diabetes to initiate and sustain behaviours needed to manage their condition throughout their lives. However, shaping diabetes education that provide culturally sensitive education that is acceptable to and supports diabetes self-management among members of ethnic minorities is needed.

Objectives:

In this study, we develop and evaluate a culturally sensitive diabetes education programme in a community health setting, focusing on Arabic, Urdu or Turkish languages (n = 100). The programme aims to support ethnic minorities with type 2 diabetes in making health-promoting decisions about their care. Also, it will produce knowledge about methods and tools to improve content and format, and about the skills of those delivering the education. Using design-based research, the development comprised three phases: needs assessment, co-creation and testing. The target groups were actively involved in all phases.

Results:

The needs assessment was based on fieldwork, workshops and interviews with the target groups and educators. Data showed that self-blame and learned helplessness undermined health-promoting decisions in the target groups. Also, a lack of clear roles between educators and peer educators, and a limited focus on goal setting in the educational setting was observed. The needs assessment informed the development of a 6 week group-based programme, supported by 11 dialogue tools. Preliminary findings show a high level of programme acceptability and participation as well as engagement in diabetes and care in the target groups.

Conclusions:

By actively involving the target groups, health care professionals and as well as health services directly engaged with the target group, the outcomes of the programme are likely to be relevant to individuals and institutions.

Key messages:

- This study gives voice to ethnic minorities with type 2 diabetes through the co-creation of a diabetes education programme aiming to support health-promoting decisions.
- Innovative and involving methods are highly relevant to develop acceptable and effective diabetes education programmes targeting ethnic minority groups.

Health promotion for unaccompanied minor asylum seekers – a qualitative evaluation

Miriam Kasztura

M Kasztura[1,2]*, M Zumstein-Shaha*[1]*, F Ninane*[3]*, P Bodenmann*[2]*, E Soom Ammann*[1]
[1]Department of Health Professions, Bern University of Applied Sciences, Bern, Switzerland
[2]Department of Vulnerabilities and Social Medicine, Center for Primary Care and Public Health, University of Lausanne, Lausanne, Switzerland
[3]Lausanne University Hospital, University of Lausanne, Lausanne, Switzerland
Contact: mkasztura@gmail.com

Background:

We evaluated a health promotion program (HPP) for unaccompanied minor asylum seekers (UMA) in the canton of Vaud, Switzerland. UMA are particularly vulnerable to a range of health issues, due to their age and migration experiences. Effective health promotion programs are key to empower them to overcome these challenges and to improve their health.

Methods:

We adopted a qualitative design with ethnographic and participatory elements to identify strengths, opportunities for improvement and appropriateness as perceived by UMA, educators and nurses responsible for UMA health care and the HPP. Data collection included observation of HPP courses, focus group discussions with UMA and interviews with educators. Analysis was based on a grounded theory in ethnography approach.

Results:

Finding include three main themes: 1) UMA's perceived low power and control, due to predominant rules and regulations and uncertainty about the future; 2) A need for health promotion in this population, due to UMA's risk behaviours and the educators' perceived discomfort with health-related issues and health promotion; 3) Practical feedback regarding topics, teaching methods and HPP organisation. Main recommendations include using effective adolescent health education methods to improve the appropriateness to age and context, enhancing participation of educators in health promotion and improving practical aspects of the HPP.

Conclusions:

We evaluated and documented health promotion practice in the hard to reach population of UMA. Feasible changes in teaching methods and multidisciplinary collaboration may improve the HPP. However, UMA's social environment needs to be taken into consideration to provide effective health promotion programs.

Key messages:

- Unaccompanied minor asylum seeker and educators perceive the health promotion program as useful and important.
- To address the health promotion needs of UMA, any program must be adaptive to the contextual complexity of UMA lives.

Access to health care among people with foreign background and the general population in Finland

Hannamaria Kuusio

H Kuusio[1]*, A Seppänen*[1]*, E Lilja*[1]*, T Vehko*[1]*, S Jokela*[1]*, P Koponen*[1]
[1]National Institute for Health and Welfare, Helsinki, Finland
Contact: hannamaria.kuusio@thl.fi

Background:

Prior studies suggest that people with foreign background (PFB) often face problems in access to health care, although access to care may vary between the different PFB groups. This study explores 1) the potential differences in perceived access to care between different PFB groups and the general population, and 2) if marital status, education, employment, self-perceived health, long-term illness, length of stay, age moved to Finland or language skills are associated with access to care among PFB.

Methods:

The data were gathered from the cross-sectional survey on well-being among the PFB (FinMONIK), conducted in Finland 2018. Its random sample consisted of 12 877 persons, aged 18-64 years and the response rate was 53%. Three items were used to assess perceived access to care: I was able to contact the place of care smoothly, I was able to make an appointment without undue delay and I was examined without undue delay (e.g. laboratory tests, X-ray, ultrasound). Logistic regression was used to test which factors were associated with accesses to care, adjusted for age, sex and region.

Results:

After controlling for age, sex and region, the results showed significant differences in access to care among different migrant groups and the general population ($p < 0.001$). Of those of Estonian background 37% felt that access to care was smooth while only 17% of those coming from Middle-East, and 26% of the general population. Employed persons, persons who had good self-perceived health, and people with no long-term illness, and those who had lived in Finland less than five years, had better access to health care. Marital status, education, language skills and age moved to Finland, were not associated with access to care.

Conclusions:

Large inequities in access to care were identified among people with foreign background. Access to services seems to be better for employed persons and those who have good self-perceived health.

Key messages:

- Special attention should be given to improve access to care among non-employed migrants.
- Migrants should not be considered as a uniform group when planning services.

Services for refugees subject to sexual and gender-based violence in Turkey and Sweden

Hannah Bradby

S Ozcurumez[2], *S Akyuz*[2], *H Bradby*[1]
[1]Sociology, Uppsala University, Uppslaa, Sweden
[2]Department of Political Science and Public Administration, Bilkent University, Ankara, Turkey
Contact: hannah.bradby@soc.uu.se

Background:

Sexual and gender-based violence affects an unknown proportion of Syrians seeking refuge from the ongoing conflict. Exile implies a vulnerability to gendered harms with consequent health effects over the short- and long-term. Services for refugees tend to presume physical gendered harms accruing to women prior to exile, with little attention paid to the effects on refugees' settlement in the new society.

Methods:

Interviews with health and social care providers of services to refugees in Sweden (n = 20) and Turkey (n = 20), including international organisations, non-government agencies, municipal and other statutory agents.

Results:

Definitions of sexual and gender-based violence that inform service delivery vary greatly between health and social care service providers, with these definitions proving critical for how services are configured and provided. Service providers may consider longer-term health problems arising from refugees' experience of sexual and gender-based violence, but refugees' prospects of integration are rarely explicitly addressed. Refugees' own views on their health and social care needs do not inform the design or development of service provision.

Conclusions:

The experience of sexual and gender-based violence by refugees from Syria is widely recognised among health and social care providers in Turkey and Sweden. However, the experience of such violence is rarely addressed as a public health problem, that is, as a social determinant of ill health and, furthermore, an impediment to successful integration. The long-term, ill effects of sexual and gender-based violence, as seen over the lifecourse, are over-looked when considering refugees.

Key messages:

- Services for refugees who have been subject to sexual and gender-based violence vary in terms of how that violence is understood and which of its outcomes are addressed.
- Sexual and gender-based violence when experienced by refugees is rarely seen as a public health problem.

Policies for tackling health inequities in migrants in an irregular situation: learning from Italy

Maurizio Marceca

F Sesti[1], *A Rosano*[2], *D Ingleby*[3], *G Baglio*[1], *R Bell*[4], *S Geraci*[5,1], *M Marceca*[6,1]
[1]Italian Society of Migration Medicine, Rome, Italy
[2]National Institute for Public Policies Analysis, Rome, Italy
[3]University of Amsterdam, Amsterdam, Netherlands
[4]UCL Institute of Health Equity, London, UK
[5]Caritas Diocese of Rome, Rome, Italy
[6]Sapienza University of Rome, Rome, Italy
Contact: maurizio.marceca@uniroma1.it

Issue:

With increasing of numbers of people moving in Europe and around the world, the health of migrants has become a key global public-health issue. Migrants in an irregular situation (MIS) represent an important part of the migration phenomenon, whether they have become irregular by entering a country without authorisation or by overstaying a visa, including whose applied unsuccessfully for asylum.

Description of the problem:

Overstaying of visas is not unusual in EU countries and during 2015 and 2016 in particular, many countries experienced a large number of unauthorised entrants. Health policies for MIS are increasingly a matter of concern. Using the 2015 Migrant Integration Policy Index Health strand (MIPEX HS) it is possible to conduct an analysis of health policies, focusing on access to health services by MIS.

Results:

Among the 34 European countries covered by the MIPEX HS, Italy's overall score of 65 is exceeded only by Switzerland (70) and Norway (67). Averaging the indicators of access for MIS, Italy obtains the highest score (83), followed by Denmark, France, the Netherlands, Romania, Spain, Sweden and Switzerland with 67. Its score for legal entitlements to health care is 75 (the same as Sweden), while reporting of MIS to the immigration authorities is prohibited and there are no sanctions against helping them. However, legislation introduced by the new government in 2018 has restricted some of their rights.

Lessons:

Current migration to Europe requires dealing with short-term health needs as well as strengthening public health and health systems in the long term. This presentation will discuss the lessons that can be learned from the comparative analysis of health policies for MIS using the MIPEX HS.

Key messages:

- Affordable health care is a human right, which should not be denied to any migrant.
- Policy analysis plays a key role in identifying interventions for promoting health equity.

Mental health treatment gap in adults of Russian, Somali, and Kurdish origin in Finland

Katja Cilenti

K Cilenti[1,2], *S Rask*[1], *H Kuusio*[1], *A Castaneda*[1]
[1]Equality and Inclusion Unit, Department of Welfare, National Institute for Health and Welfare, Helsinki, Finland
[2]Doctoral Programme in Population Health, Faculty of Medicine, University of Helsinki, Helsinki, Finland
Contact: katja.cilenti@helsinki.fi

Background:
Migration affects migrating persons' health in many levels. Populations of migrant origin, and in particular refugees, are known to have an increased risk of mental ill health. Previous research from Finland has shown that the prevalence of mental health symptoms is significantly higher among Russian origin women and Kurdish origin men and women than in the general population. Building on prior research, we explore the prevalence of perceived need for mental healthcare among Russian, Somali, and Kurdish origin populations and compare this to the general population in Finland. Additionally, we present prevalence of mental health treatment gap in these groups.

Methods:
We used data from the Finnish Migrant Health and Wellbeing Study (n = 1404) and the Health 2011 Survey (n = 1459). Prevalence was calculated using predicted margins (95% confidence level). P-value of less than 0.05 was considered significant. Mental health treatment gap was examined by constructing a combined variable of perceived need for mental health services and prevalence of service use.

Results:
The perceived need for mental health services was higher in Kurdish origin persons (16%) and lower in Somali origin persons (<1%) than in the general population (8%). Both Kurdish origin men (11%) and women (20%) expressed more need for mental health services than men (4%) and women (11%) in the general population. The mental health treatment gap was highest in Russian origin women (10%) and Kurdish origin women (10%) and men (8%). For the general population, the treatment gap was only 1% (men 2 %, women <1%).

Conclusions:
Untreated mental health problems are unjust, problematic and can be a source of great human suffering. Evidence from Finland shows that especially persons of Kurdish origin experience a mental health treatment gap. To expand coverage and reduce inequalities in health services, national development projects (e.g. PALOMA) have been launched to improve mental healthcare.

Key messages:

- Perceived need for mental health services is more common among certain foreign-born populations than the general population in Finland; this is in line with prior research on mental health symptoms.
- Untreated mental health problems are unjust, problematic and can be a source of great human suffering; evidence of mental health treatment gap should lead to improved access to mental health services.

Increase of tuberculosis incidence in Ile-de-France region and the role of recent migration

Yassoungo Silue

Y Silue[1], A Lepoutre[1], I Mounchetrou-Njoya[1], S Lapora[2], C Calba[1], JP Guthmann[2]
[1]Regions Division, Sante Publique France, Paris, France
[2]Infectious Division, Sante Publique France, Saint-Maurice, France
Contact: yassoungo.silue@santepubliquefrance.fr

Background:
In metropolitan France and in the Ile-de-France region, the incidence of tuberculosis has globally decreased since the year 2000 and has stabilized from 2011 to 2015. This study analysed the evolution of tuberculosis in the Ile-de-France region between 2015 and 2017.

Methods:
We analysed tuberculosis cases reported in Ile-de-France from 2015 to 2017; 2015 was considered as the baseline year. Incidence rates of reported tuberculosis cases were estimated using French census data for the corresponding year for the denominator. Age-standardized rates were estimated for each of the 8 departments of the region based on the Ile-de-France region population. Foreigners' population was based on the 2015 French census data. Differences in incidence and proportions were tested with the CHI2 statistic (STATA® v14.0).

Results:
The incidence of tuberculosis increased in the Ile-de-France region from 14.6 to 15.8/100 000 pop. between 2015 and 2017 (+8.2%, $p < 0.01$). In this region, all department's incidence were above 10/100 000 pop. in 2017. Sub-regional disparities were observed, with an important increase of the incidence in Paris, from 13,5 to 16.8/100 000 pop. between 2015 and 2017 ($p < 0,01$). The incidence rates among foreigners increased from 44.6 to 51.7/100 000 pop. ($p < 0.01$) and the proportion of tuberculosis cases among foreigners who arrived in France less than 2 years ago increased from 23% to 32% ($p < 0.01$), between 2015 and 2017. The incidence rates of tuberculosis cases increased particularly in men, foreigners, and recent migrants.

Conclusions:
The incidence of tuberculosis increased in the Ile-de-France region in 2016 and 2017, particularly in newly arrived migrants. This situation requires actions to better detect and manage tuberculosis in this specific population.

Key messages:

- The incidence of tuberculosis increased in the Ile-de-France region.
- The incidence of tuberculosis increased in vulnerable population in relation with recent migration.

Migrants' social determinants of health: living conditions, violence exposure, access to healthcare

Estelle Spoel

E Spoel[1], K Accoe[2], S Heymans[3], P Verbeeren[4], X de Béthune[1]
[1]Health Unit, Operational Department, Doctors of the World, Brussels, Belgium
[2]Health and Equity Unit, Institute of Tropical Medicine, Antwerp, Belgium
[3]Operational Department, Doctors of the World, Brussels, Belgium
[4]General Direction, Doctors of the World, Brussels, Belgium
Contact: estelle.spoel@medecinsdumonde.be

Background:
WHO and some other authors consider migration as a social determinant of health. MdM identifies it being composed of different factors such as living conditions, exposure to violence and access to healthcare.

Methods:
We analysed a comparative quali-quantitative survey in 4 locations, in Niger, Morocco and Tunisia, based on questionnaires and focus groups, with basic statistical tests and a complementary qualitative analysis.

Results:
461 migrants were interviewed, 59% women, median age 28 year, 98.5% sub-Saharan African origin, 63% with no legal documents.

46% travelled for more than 6 months, 47% stayed in the country of interview more than 12 months, even if most of them wanted to go on. 83.8% faced violence during their life, 61% during migration.

58% of violence was psychological in nature, confiscation of money and/or documents, or violence by police or army. The types of violence's vary according to gender and localization. Only 39% did not face barriers to access to healthcare. The 3 main barriers are financial, lack of understanding of the health system and discrimination. 50% of migrants considered their health status as medium, bad or very bad, what is insufficient for such a young population.

Conclusions:
Some events are always part of migration: long duration, violence, barriers to access healthcare, with an overall negative impact on health. Recommendations: Authorities should address the structural factors of violence against migrants. The health needs of migrants should be taken into account in policies at all levels. Health services should always consider migrants' needs: determinants of health, mental health,

consequences of violence and difficult access to healthcare. Research needs: What are the specific social determinants of health in migration?

Key messages:

- The health status of migrants seems to get worse along the road.
- Some migration events should be considered as social determinants of health and addressed by health services.

Asylum seekers' mental health in the Finnish Asylum Seekers Health and Wellbeing Survey (TERTTU)

Anu Castaneda

AE Castaneda[1], E Lilja[1], F Garoff[1], KL Mustonen[1], A Ahmed[1], N Skogberg[1]
[1]Equality and Inclusion, National Institute for Health and Welfare, Helsinki, Finland
Contact: anu.castaneda@thl.fi

Background:

Asylum seekers have major health and well-being burdens, including mental health. However, there is a lack of population-based survey data on the health status and service needs of asylum seekers in Europe. The TERTTU-project was launched to fill these information gaps and to develop the current health examination protocol for assessing the health, well-being and need for health care services, including mental health, of newly arrived asylum seekers.

Methods:

As part of the TERTTU-project, systematic, nationally representative data was collected in 2018 by conducting a health examination and a face-to-face interview survey in reception centers in Finland (n = 1087). The sample was drawn from the Finnish Immigration Services electronic asylum database. Mental health was assessed with the HSCL and PROTECT questionnaires (SDQ among the children), along with questions of potentially traumatic experiences.

Results:

39% (95% CI 35,6-42,6) of the adults had current severe depressive and anxiety symptoms, 50% (95% CI 46,9-53,9) had an increased risk for PTSD, and 83% (95% CI 80,0-85,3) had experienced at least one potentially traumatic event before arriving to Finland. The most common psychosocial symptoms among 2-6 year-olds were behavioral symptoms (49%) and difficulties in peer relationships (37%). Difficulties in peer relationships were also common among 7-17 year-olds (49%), followed by challenges in the emotional domain (42%).

Conclusions:

Potentially traumatic experiences and mental health problems are common among asylum seekers in Finland. Based on the survey-data, a national health examination protocol will be developed in 2019 to improve assessment and identification and to enable systematic health monitoring and evidence-based development of services for asylum seekers. A common health examination protocol will also unify practices across reception centers all over the country.

Key messages:

- Potentially traumatic experiences and mental health problems are common among asylum seekers in Finland.
- A national health examination protocol allows for the early identification of vulnerable groups and individuals.

Barriers to health access for women during forced migration: An exploratory study

Brighid Scanlon

J Durham[1]
[1]School of Public Health and Social Work, Queensland University of Technology, Kelvin Grove, Australia
Contact: b.scanlon@uq.net.au

Background:

Mass migration is a global crisis that has a number of significant public health implications for Europe. With more than a billion migrants worldwide, Europe receives a significant proportion of those, many of whom are forced migrants, possessing particular health and social vulnerabilities. Many forced migrants transit through, or settle within Europe. Despite this, there is a dearth of literature examining the experiences and perspectives of forced migrants or the barriers they may face in accessing health services. Understanding these barriers is integral to developing an effective international response.

Methods:

Using purposive sampling, 8 female key informants from displacement backgrounds were recruited for in-depth interviews from Queensland, Australia. The interview questions focused on past experiences of accessing healthcare during displacement and were formulated around the 5 dimensions of health access described by Levesque, Harris and Russell (2013). Data was analysed using qualitative content analysis.

Results:

Under the five dimensions of health access (approachability, acceptability, availability, affordability and appropriateness) twelve sub-themes were identified that were specific to the displacement context. Common sub-themes included mistrust of health services, irregularity in access, focus on acute health conditions, limited healthcare capacity, self-treatment; with pharmacies often the first point of contact, and the neglected health needs of vulnerable populations, such as women.

Conclusions:

The current global mass population flows, display a need to consider the long-term health effects of displacement and how these experiences shape migrants' future health-seeking behaviours. A significant number of forced migrants transit or settle within Europe and therefore there is a demonstrable need to understand the perspectives and experiences of those individuals, if equitable health access is to be attained.

Key messages:

- This is the first study to the authors' knowledge that applies a structured framework to the displacement experience, providing novel insights of an under-researched population.
- It is essential to understand the perceived barriers to health access of forced migrants in order to reduce morbidity, mortality, inequity and associated healthcare costs.

Self-reported discrimination in health surveys: results from a scoping review

Katja Kajikhina

K Kajikhina[1], N Sarma[1], M Schumann[1], T Lampert[1], C Santos-Hövener[1]
[1]Social Determinants of Health, Rober Koch Institute, Berlin, Germany
Contact: KajikhinaK@rki.de

Background:

Surveying perceived discrimination in the context of health monitoring can help to clarify the connection between unequal treatment and health. We aimed to review, identify and extract data on definitions and measures of discrimination.

Methods:

A scoping review of both peer reviewed and grey literature was conducted. Survey instruments used in representative surveys in Germany were compared and discussed regarding their strengths and limitations. Ethical and methodical guidelines and policy reports by WHO, ECDC, EUPHA, migration research institutions and local NGOs were considered.

Results:

Research from North America, South Africa and, to a lesser extent, European countries shows a clear link between discrimination and health. Various scales, individual items and instruments operationalize discrimination as worse treatment in everyday life or disadvantage in the structural field (authorities, housing market, working life). Possible reasons and frequencies of experiences are surveyed. Additional instruments are used to evaluate moderators such as vigilance or coping. Besides validity and reliability, ethical aspects such as voluntary self-disclosure, avoidance of external ascriptions and assessment of multiple dimensions of discrimination should be considered.

Conclusions:

We propose a three-stage instrument for surveying perceived discrimination in German health surveys. First, the frequency of interpersonal experiences is surveyed by the everyday discrimination scale validated for different settings. Second, possible reasons for the reported experiences are asked, based on the categories of the German General Equal Treatment Act. Lastly, questions on discrimination in health care and by public authorities will address specific public health areas.

Key messages:

- Only few studies are available on discrimination and health in Europe, more is needed to effectively address health disparities.
- We propose to consider specific ethical and methodical aspects when surveying perceived discrimination as a health determinant.

Self-reported health conditions among refugees and asylum-seekers (AS) in Italian hosting centres

Marco Fonzo

C Bertoncello[1], M Fonzo[1], S Zanovello[1], S Ferretti[1], R Brunetta[2], G Gallo[3], V Baldo[1]
[1]Hygiene and Public Health Unit, DCTV, University of Padova, Padova, Italy
[2]Local Health Unit, Azienda ULSS 7, Padova, Italy
[3]Local Health Unit, Azienda ULSS 6, Padova, Italy
Contact: marco.fonzo@studenti.unipd.it

In recent years, Italy has been facing an increase in migration flows. Migrants are vulnerable: understanding underlying conditions is essential to provide suitable assistance. We investigated health conditions of AS arrived in 2014-2016 and living in hosting centres in northeast Italy. AS filled in a multi-language questionnaire. Demographic characteristics, self-reported health status and travel conditions were recorded. Logistic regression (adjusting for age, sea/land arrival, marital status, education level), $\chi 2$ and Fisher's test were used (significance at .05). 216 AS were included, of which 98% males and 91% aged 15-34; 72% arrived by sea, of which 96% from West Africa (WA), while 94% of land arrivals were from the Indian Subcontinent (IS). 62% experienced health problems after arrival. This condition was significantly associated with sea arrival (aOR 2.9), married status (aOR 3.1) and higher education levels. Most problems involved GI tract (13%), teeth (17%) and skin (25%), being AS from WA (31%) more affected than IS (10%). STDs and alcohol were considered as health threats by more than 30% of AS, while smoking, diet and drugs were ignored; 27% and 23% declared to smoke and consume alcohol, respectively, with no substantial change compared with pre-arrival habits. 88% considered their current health good/satisfactory. While anxiety seemed to affect 10% of AS, 30% reported symptoms of depression, especially those arrived by sea (aOR 3.1) and with higher education. However, physical (94%) and mental (88%) health was considered improved/stable after arrival. Perceived health is overall good. However, AS by sea, with higher education or experiencing family breakdown suffer more from both physical and mental issues, especially depression. Long waiting times to grant refugee status and partial fulfilment of life expectations may worsen health conditions. Customised solutions in hosting centres may be encouraged, considering travel conditions and cultural background.

Key messages:

- Migrants' health in hosting centres is good; AS by sea, married and with higher education are more at risk, especially as regards mental health; depression warning signs must not go unnoticed.
- AS in hosting centres represent a heterogeneous population: they may benefit from a more tailored assistance, considering differences in travel conditions, cultural background and life expectations.

Health experiences of asylum seekers and refugees in Wales

Catherine Weatherup

R Scott[1], L Ellis[1], A Khanom[2], M Rhydderch[3], G Richardson[1], D Russell[2], I Russell[2], H Snooks[2]
[1]Policy & International Health, Public Health Wales, Cardiff, UK
[2]Patient and Population Health and Informatics, Swansea University, Swansea, UK
[3]Displaced People in Action, Displaced People in Action, Cardiff, UK
Contact: Catherine.Weatherup@wales.nhs.uk

There are concerns that people seeking sanctuary (asylum seekers and refugees) in Wales, UK, have unmet health needs and face difficulties accessing services, but little collated evidence. This study addressed this gap to inform policy and practice in reducing health inequities. It aimed to: investigate the health, wellbeing and healthcare experiences of adults seeking sanctuary in Wales, including the views of healthcare recipients and providers; and establish what helped or hindered the healthcare experiences of those seeking sanctuary. It is the most comprehensive study of this population in Wales.

A mixed-method approach was taken, including a literature search, a cross-sectional survey of 210 adults seeking sanctuary, telephone interviews with 32 health professionals and third sector support workers, and 8 focus groups including 57 people seeking sanctuary and those supporting them.

Eight trained volunteer peer researchers, themselves asylum seekers or refugees, administered the surveys. Interviews were digitally recorded, transcribed and analysed using a standard framework.

The literature search identified 5 themes that help or hinder people seeking sanctuary to access healthcare. The survey found 79% of respondents attended an initial health assessment on arriving in Wales, with 94% currently registered with Primary healthcare. 64% reported difficulties in accessing health services. Awareness of services was mixed, with 66% having used healthcare in working hours (planned) and 28% out of hours (unplanned).

Mainstream health professionals felt they lack capacity to deliver care effectively due to time and other pressures on the healthcare system and the need for appropriate translation/interpretation services.

This study triangulates the experiences of people seeking sanctuary with those providing healthcare and general support. Peer researchers maximised sanctuary seekers' participation. Many of its methods and findings have relevance to other countries in Europe.

Key messages:

- Improving health equity is key to realising Wales' ambition to become a Nation of Sanctuary.
- Peer Researchers enabled participation by sanctuary seekers and revealed useful findings to steer future policy and practice.

Significance and challenges of assessing health literacy among migrants

Eva-Maria Berens

EM Berens[1], M Mensing[1], J Klinger[2], S Carol[2], D Schaeffer[1]
[1]Interdisciplinary Center for Health Literacy Research, Bielefeld University, Faculty of Public Health, Health Services Research and Nursing Science, Bielefeld, Germany
[2]Institute of Sociology and Social Psychology, University of Cologne, Cologne, Germany
Contact: eva-maria.berens@uni-bielefeld.de

Background:

People with a migration background account for a large part of the population in many European countries. Although health literacy - knowledge, motivation, and competencies to process health information - is a key determinant of health, research on health literacy specifically among migrants in Europe is scarce. The aim is therefore to review and further develop the concept and assessment of migrant-specific health literacy for future use in a migrant health literacy survey (HLS-MIG) in Germany.

Methods:

A literature search in Pubmed was performed in April 2019 to identify studies regarding health literacy, health outcomes and knowledge among migrant populations in Europe. A special focus was put on the conceptualization and operationalization of health literacy among migrants.

Results:

So far, health literacy among migrants has mostly been measured using general health literacy measurement tools, that is, performance-based and self-assessment instruments as the HLS-EU-Q. Migration-specific competences, such as finding information about health in mother tongue, or outcomes of deficient HL have so far received little attention, except for e.g. the GMK-12, developed as a complement to the HLS-EU-Q16 in the Austrian context.

Conclusions:

The use of performance-based instruments in the local language primarily provides information about existing linguistic deficits, but hardly on competencies and abilities in dealing with health information. General self-assessment tools, on the other hand, allow the identification of such competences, difficulties and challenges. However, it is necessary to take greater account of migration-specific competences, habits and obstacles in the future, in order to develop tailored interventions for individuals and organizational aspects, supporting health information processing among migrants. Furthermore, studies also need to pay attention to migrant specific health problems and prerequisites.

Key messages:

- Research focussing on migrant health literacy is scarce.
- More attention needs to be paid to migrant specific competencies, habits and challenges.

Health among immigrants in Norway, results from the Living Condition Survey among immigrants 2016

Marte Kjøllesdal

MK Kjøllesdal[1], ML Straiton[2], C Øien-Ødegaard[2], A Aambø[1], O Holmboe[1], R Johansen[2], NK Grewal[1], T Indseth[1]

[1]Health Services Research, Norwegian Public Health Institute, Oslo, Norway

[2]Domain of Mental and Physical Health, Norwegian Public Health Institute, Oslo, Norway

Contact: MarteKarolineRaberg.Kjollesdal@fhi.no

Introduction:

To manage immigrants̀ health needs is an important challenge for the society. This report gives knowledge about the status of immigrant health in Norway, which can be used in planning of health services.

Methods:

Statistics Norway carried out a Living Condition Survey among immigrants in 2016. We report the prevalence of health outcomes (self-reported health, cardiovascular diseases, hypertension, diabetes, back- and neck problems, impaired functioning, mental health problems, problems with sleeping, overweight) and lifestyle (alcohol, smoking, physical activity) by country of origin and assess associations between health and sociodemographic (age, education, income) and migration related (age at immigration, duration of residence, Norwegian proficiency) variables, as well as discrimination and employment. Immigrants from twelve countries were interviewed. The questionnaire was translated into the main languages in the twelve countries and English. In this report, 4399 participants aged 16-66 years were included.

Results:

There were large variations in health according to country of origin and gender. Immigrants experienced a deterioration in health at younger age than non-immigrants did. The educational gradient in health was less pronounced among immigrants than among others. Perceived discrimination was related to mental health problems. Some immigrant groups had a high proportion of smokers. In most groups a considerable proportion was drinking alcohol and a low proportion were physically active.

Conclusions:

Future research should take into account differences in health according to country of origin and gender. The importance of physical and social circumstances for immigrant health emphasizes the need for structural population-based initiatives to promote health.

Key messages:

- Immigrant health varies by country of origin and gender.
- Physical and social environment is important for immigrant health.

Access to abortion of undocumented migrants seen by Médecins du Monde in the Humanitarian Hub

Felipe Rojas Lopez

L Ben Abdelahfidh[1], J Huber[1], F Rojas López[1], C Glorie[2], I Vanden Bussche[1], C Coiret[1], E Spoel[1], A-L Pignard[2], S Heymans[2], X De Bethune[1]

[1]Département Santé, Médecins du Monde, Brussels, Belgium

[2]Département Opérationel, Médecins du Monde, Brussels, Belgium

Contact: Rojaslopez.felipe@gmail.com

As of June 2017, the population of the Maximillian Park (an undocumented migrant camp in Brussels) is mainly Eritrean and Sudanese migrants who intend to continue their journey to the United Kingdom (Depraetere, 2017; Daher, 2018). In response to demanding needs, Médecins du Monde together with 8 organisations, created a one-stop service centre, The Humanitarian Hub, in January 2018 to offer a set of basic services to the migrants.

The Hub implemented a voluntary de-medicalized midwifery clinic. The medical team noted an under-representation of women, 40 out of 745 (5,4%), while the coordination team identified a number of complex unwanted pregnancies, many of which relating to violence. Accessing free abortion for undocumented women in Belgium requires the Urgent Medical Assistance certificate. This often takes several weeks, making it unrealistic to obtain in time for an abortion. Accordingly, the women or family planning centres cover the financial cost. The Hub's midwifery clinic thus focused on building trust with the women, and facilitated referrals to family planning centres.

By taking steps to create a more gender-sensitive Hub, the proportion of women seeking consultations doubled. In 2018, 955 out of 8990 (10,6%) patients were women, totalling 324 midwifery consultations. 65 of these women were pregnant, and the 23 who sought abortion were referred to family planning centres. None had Urgent Medical Assistance.

It is crucial to consider the particularities of a population and their social determinants of health when implementing a holistic system. For instance, focusing on violent experiences in medical consultations can help better understand women's situation. The coordination between The Hub and family planning centres helped in reducing barriers for migrant women. The project has seen success, thanks to the flexibility of the family planning centres in quickly receiving these pregnant women, and to the four centres who covered abortion costs.

Key messages:

- It is evident that the magnitude of these women's situation is undervalued, thus it is important to increase sensitization and advocacy in order to offer them greater support.
- The Hub has provided a number of services for undocumented migrants, notably abortion, and removed some barriers in accessing care. However, it is a fragile solution to a structural problem.

Empowering minor migrants: peer support program Nantes

Le Grand Eric

S Combes[1,3], D Kardiana[2], E Le Grand[1], D Moreau[1], M Quinette[4], S Sauzède[2]

[1]Université de Rennes, EHESP, CNRS, ARENES – UMR 6051, Ren, École des Hautes Études en Santé Publique, Rennes, France

[2]École des Hautes Études en Santé Publique, Rennes, France

[3]French Collaborative Institute on Migration, Collège de France, Paris, France
[4]Médecins du Monde, Doctors of the World, Nantes, France
Contact: ericlegrand35@orange.fr

Background:

Under-aged migrants (UAMs) may see their legal minority unrecognised by the French state. If they confront this decision at court, they stand in a legal void. They can benefit from a direct access to State Medical Aid and are not submitted to a minimum period of 3 months of staying in France unlike adults. Moreover, when accessing care, unrecognised UAMs are in an unclear situation as they are minors without legal representation. This research is based on a newly created program ran by Doctors of the World (MDM) in Nantes, aiming to enhance UAMs access to health care and rights through peer-support. Peer-support is intended to develop the empowerment the UAM and help them to be able to be the authors of their life thus develop their own abilities (Le Grand, 2018). The role of empowerment in health access is established (Wallerstein, 2006). The research aims at identifying the obstacles and levers in the implementation of the program, the modifications it can cause in the program.

Methods:

The research is based on 3 months ethnographical observations, 9 formal interviews with UAM, 5 with professionals, and informal interviews.

Results:

We identify that volunteers share a different perception of what is empowerment. Some would leave quite a large autonomy to UAMs while others find it difficult to alter the organisation to give space to UAMs. Finally, self-help mainly develops abilities of those UAMs who were more resourceful.

Conclusions:

The analysis shows that a successful program of empowerment rely on shared views of its meaning. Moreover it shows that empowerment may help mainly those resourceful thus exacerbate some inequalities in ressources.

Key messages:

- The notions of empowerment and peer-support need to be well understood by all.
- Empowerment, as a side effect first exacerbates some inequalities of resources among UAMs.

Improving access to health of Migrants in France. Qualitative assessment of a national guide

Emmanuelle Hamel

E Hamel[1], M Karrer[1]
[1]Elderly and Vulnerable Populations, Santé Publique France, Saint Maurice, France
Contact: emmanuelle.hamel@santepubliquefrance.fr

The National Public Health Agency and the Committee for the healthcare of persons in exile are providing, in the service of professionals, a Practical Guide for the care and the accompaniment of Migrants Foreigners living in precarious conditions, in France. The 2015 edition of this guide has been subjected to qualitative assessment in order to gather information regarding its use, the way it is perceived by its users, as well as their subsequent expectations, in order to design a new version that is more adapted to their needs.

The study was carried out in December 2018 by an independent market research institute with the following design:

- 24 face-to-face interviews, whose duration was 1h30min, involving current users or past users: 6 working in structures specialised in accommodation for migrants, 6 in health care facilities, 6 in municipal or departmental social service facilities.
- 3 focus groups, of 7-8 people, whose duration was 2H30min, involving potential future users of the guide.

The recruitment of the participants took place in 3 cities as well as the overseas departments.

The findings show:

- the legitimacy of this guide which is co-produced by an official national agency and an association recognized for its expertise.
- the interest of a transversal and multi-professional approach which allows to better grasp the social, legal and medical support and care
- the need for information and operational resources

This assessment underlines the relevance of the content and the symbolic importance of this guide which 'materializes' the needs in terms of access to the rights and health of migrant people, often overlooked by professionals and administrations. It is thus a vehicle of vocational training and advocacy on this subject. The study provides concrete ways of optimization, particularly via digitalization, in order to cope with the rapid obsolescence of information, the availability of local directories and the need for exchange of professional practices.

Key messages:

- A national guide co written by a national agency and an association is a relevant tool to draw attention to migrants needs.
- Qualitative assessment highlighted the operationnal and symbolic role of this guide to foster cross professionnal work.

Gender differences of health literacy in first and second generation migrants: A systematic review

Digo Chakraverty

D Chakraverty[1], A Baumeister[2,3], A Aldin[4], I Monsef[4], T Jakob[4], ÜS Seven[1], G Anapa[1], N Skoetz[5], C Woopen[2,3], E Kalbe[1]
[1]Medical Psychology, Neuropsychology and Gender Studies, Center for Neuropsychological Diagnostics and Intervention (CeNDI), University of Cologne, Medical Faculty and University Hospital of Cologne, Cologne, Germany
[2]Research Unit Ethics, University of Cologne, Medical Faculty and University Hospital of Cologne, Cologne, Germany
[3]Cologne Center for Ethics, Rights, Economics and Social Sciences of Health (CERES), University of Cologne, Cologne, Germany
[4]Department I of Internal Medicine, Cochrane Haematological Malignancies, Center for Integrated Oncology Aachen Bonn Cologne Duesseldorf University of Cologne, Medical Faculty and University Hospital of Cologne, Cologne, Germany
[5]Cochrane Cancer, Center for Integrated Oncology Aachen Bonn Cologne Duesseldorf, University of Cologne, Medical Faculty and University Hospital of Cologne, Cologne, Germany
Contact: digo.chakraverty@uk-koeln.de

Background:

Health literacy, defined as all skills and capabilities that enable a person to access, understand, appraise and apply health information, is a key factor regarding disease management, health outcomes, and health-decision-making. Internationally, migrants have been identified as a high-risk group for limited health literacy. However, it remains unclear if female and male migrants process health information differently. This systematic review aims to analyze gender differences in the health literacy of first and second generation migrants.

Methods:

We performed a systematic review according to PRISMA guidelines. We searched OVID (MEDLINE), PsychInfo and CINAHL for original articles providing extractable data on the health literacy of male and/or female migrants. Two reviewers independently reviewed abstracts and full text articles for according to predefined inclusion criteria, including the use of a validated health literacy measurement tool, applying it to first and/or second generation adult migrants. We adapted a data extraction sheet from the Cochrane Collaboration for extracting relevant data. The included studies were evaluated against a standardized set of quality criteria.

Results:

Our search yielded 3411 records. We included 48 studies, of which 37 were conducted in the USA and Canada, with 22 focusing Hispanic and Asian immigrants' functional health literacy; the nine European studies examined a variety of work migrants and refugees using a comprehensive approach (e.g. measured by the HLS-EU-Q47). Thus, a strong heterogeneity in defining and measuring health literacy and in the populations examined can be stated. 15 studies exclusively examined the health literacy of women; none dealt with men only.

Conclusions:

The heterogeneity in defining and measuring health literacy in migrants as well as the diversity of the populations studied make it difficult to compare international research in this area. There is a lack of research focusing male migrants.

Key messages:

- International research on health literacy with gender-specific data on migrants reveals a strong heterogeneity in defining and measuring health literacy.
- International research on health literacy with gender-specific data on migrants reveals a lack of studies regarding male migrants' health literacy.

Episodes of violence suffered by migrants transiting Libya, Italy and France

Laura Reques Sastre

L Reques[1], C Rolland[1], E Aranda[1], A Grippon[2], N Fallet[2], C Bensimon[2], N Godard[3], C Reboul[4], C Gutton[3], N Luhmann[1]
[1]Research and Learning Unit, Médecins du Monde, Paris, France
[2]Centre d'Accueil Soins et Orientation de Saint-Denis, Médecins du Monde, Paris, France
[3]Operations France, Médecins du Monde, Paris, France
[4]Health and Advocacy Direction, Médecins du Monde, Paris, France
Contact: requeslaura@hotmail.com

Background:

The Central Mediterranean is one of the most dangerous migration routes from Africa. Violence perpetrated to migrants in Libya and host countries has been documented but not rigorously quantified. The objective of the study was to estimate the prevalence of violence suffered in Libya, Italy and France by migrants consulting Médecins du Monde programs.

Methods:

Monocentric cross-sectional study. Inclusion criteria: migrants over 18 years old, transiting through Libya, arrived in Europe from 2017 and consulting in Saint Denis Health Center. Exclusion criteria: psycotraumatic manifestations. A sample size of 72 individuals was calculated. An ad-hoc questionnaire was created through Kobo Collect. Proportion and frequency of physical, privation and sexual violence, as well as health care and shelter access were measured in each country.

Results:

95 individuals were recruited and 72 were interviewed (16 refused 7 were excluded) from February to April 2019. 76.3% were men, mean age was 31.6 years, 76.4% had low educational level, 66.7% were from Ivory Coast and 58.3% left their country for security reasons. In Libya, length of stay was 180 days, global proportion of individuals suffering from violence (GPISV) was 98.1% for men and 88.2% for women. Prevalence of physical, privation and sexual violence was 94.1%, 84.3% and 17.6% for men, and 85.7%, 93.3% and 60.0% for women. Health care access in Libya was inexistent. In Italy, GPISV was 31.8% for men and 28.5% for women. Health care access was 41.4%. In France, GPISV was 20.0% for men and 12.5% for women and shelter access was 44.3%. 60.3% of the participants reported need of psychological support.

Conclusions:

The vast majority of migrants testify suffering from direct violence during migration, specially dramatic in Libya. Women have a particular risk of sexual violence. In Europe, the main problems are the lack of health care access in Italy and precarious living conditions in France. Mental health support is urgent.

Key messages:

- The vast majority of migrants testify suffering from direct violence during migration, specially dramatic in Libya.
- In Europe, the main problems are related to lack of health care access in Italy and the precarious living conditions in France. Mental health support is urgent.

Self Rated Health among Syrian refugees in Lebanon and Norway – a cross sectional study

Jasmin Haj-Younes

J Haj-Younes[1], EM Strømme[1], W Hasha[1], E Abildsnes[3], LT Fadnes[1], B Kumar[2], E Diaz[1,2]
[1]Department of Global Public Health and Primary Care, University of Bergen, Bergen, Norway
[2]Unit for Migration and Health, Norwegian Institute of Public Health, Oslo, Norway
[3]Kristiansand Municipality, Kristiansand Municipality, Kristiansand, Norway
Contact: jasmin.haj-younes@uib.no

Background:

Refugees are often exposed to various stressors before, during and after migration that can cause adverse health effects. Prior research indicates that the health status of refugees is a significant factor in determining their success in resettlement. This study aims to assess self-rated health (SRH) and factors associated with SRH among Syrian refugees in Lebanon and Norway.

Methods:

The study uses a cross-sectional design with data from a self-administered survey among 827 adult Syrian asylum seekers of whom 506 were recruited in Lebanon, and 321 in Norway. Inclusion criteria were subjects who self-identified as Syrian nationals above the age of 16. The survey was conducted in 2017 and 2018 in collaboration with International Organization of Migration in Lebanon and through mandatory educational activities in Norway. Data analysis was performed for the main outcome self-rated health (SRH), a validated health status indicator, which was dichotomized into ''good'' and ''poor'' SRH. Odds Ratios for poor SRH were estimated adjusting for age, gender and country of residence.

Results:

A total of 827 of 972 (85%) who were invited answered the questionnaire. The mean age was 33 years and 74% were men. Factors associated with good SRH were being Kurdish (AOR: 0.48 (0.23 to 0.97)) compared to Arabic ethnicity, being married (AOR 0.54 (0.29 to 0.99)) compared to being single, migrating alone (AOR 0.59 (0.37 to 0.96)) compared to co-migration and having low health literacy level (AOR: 0.64 (0.42 to 0.93)). In contrast, poor SRH was significantly increased with long time in transit country/ies (AOR 1.49 (1.07 to 2.06)) and with older age (age 30-34 AOR 3.2, age 35-39 AOR 2.2, age 40 + AOR 2.6) compared to age group 16-24.

Conclusions:

Older refugees and those who stay long time in transit are at great risk of reporting poor SRH. Some of the factors associated with better health, like Kurdish ethnicity, low health literacy or migrating alone, deserve further research.

Key messages:

- Age and long stay in transit is associated with poor SRH among Syrian refugees.
- Demographic background and migrant related factors should be taken into account when planning refugee resettlement and healthcare provision.

Strategies to enhance follow-up response in a cohort study with Berliners of Turkish descent

Lilian Krist

L Krist[1], C Dornquast[1], T Reinhold[1], S Solak[1], M Durak[1], T Keil[1,2,3]
[1]Institute of Social Medicine, Epidemiology & Health Economics, Charité Universitätsmedizin Berlin, Berlin, Germany
[2]Institute for Clinical Epidemiology and Biometry, University of Würzburg, Würzburg, Germany
[3]Institute for Health Resort Medicine and Health Promotion, Bavarian Health and Food Safety Authority, Bad Kissingen, Germany
Contact: lilian.krist@charite.de

Background:

Follow-up participation and retention are essential in long-term cohort studies. Loss to follow up may reduce the power of statistical analyses and external validity. The aim of this analysis was to evaluate the response after different contact methods in a cohort study with Berliners of Turkish descent and to compare characteristics of participants with those of non-participants.

Methods:

In 2012-2013, Berliners with a Turkish migration background were recruited for this cohort study that initially aimed to examine recruitment strategies. The participants were contacted again 5 years later via postal mail and were asked to complete a questionnaire on the onset of new diseases and health care utilization. Written reminders, phone calls, and home visits were used to increase the response. Study documents were available in German and Turkish language. In descriptive analyses, we examined the response rate in relation to the recruitment approach. A regression analysis was conducted to investigate associations between individual, socioeconomic, and medical factors and the response.

Results:

Out of 560 contacted persons, the neutral non-response (unknown address or death) was 13.6%. Of the remaining 484, 234 persons participated in the follow-up (women: 63.1%, mean age±SD: 49.8±12.6 years). The response was 16.1% after the first invitation letter, 24.2% after phone calls, 33.3% and 42.1% with a first and a second reminder letter, respectively, and 48.3% after home visits. The participants had more often German citizenship and a higher net income at baseline than non-participants. Migration generation, age, sex, education, and chronic diseases were not associated with participation (preliminary results).

Conclusions:

In our participants with a migration background, every additional contact effort including home visits further increased cohort retention. Investing in comprehensive retention efforts may lead to studies that are more valid to examine the health of migrants.

Key messages:

- Investing in different contact efforts including reminder letters and home visits can improve follow-up response in longitudinal studies.
- Retention strategies should be used in longitudinal studies to increase statistical power and external validity.

Training development in the ORAMMA (Operational Refugee and Migrant Maternal Approach) project

Elena Petelos

E Petelos[1,2]*, V Vivilaki*[3]*, M Papadakaki*[4]*, E Sioti*[3]*, E Triantafyllou*[3]
[1]Clinic of Social and Family Medicine, School of Medicine, University of Crete, Iraklion, Greece
[2]Health Services Research, Care and Public Health Research Institute, Faculty of Health, Medicine and Life Sciences, Maastricht University, Maastricht, Netherlands
[3]Department of Midwifery, University of West Attica, Athens, Greece
[4]Laboratory of Health and Road Safety, Department of Social Work, School of Health and Social Welfare, Technological Educational Institute of Crete, Iraklion, Greece
Contact: elena.petelos@med.uoc.gr

Background:

ORAMMA is a European capacity-building project (GR, NL, UK) for pregnant migrant, asylum-seeking and refugee (MAR) women to improve maternal and newborn outcomes. ORAMMA is an operational and strategic approach for mother-centred, community-oriented, gender-sensitive, interdisciplinary and compassionate care, to meet the needs of MAR women in Europe.

Objectives:

ORAMMA developed training for midwives and other primary health and social care (PC) professionals to meet the needs of MAR women. Methodology comprised three phases: evidence synthesis and needs assessment, training material development, and community enablement through locally recruited women in the innovative role of Maternal Peer Supporters (MPSs).

Results:

Needs assessment highlighted the need to train ORAMMA's teams of midwives and other PC professionals to care for women who suffered undue hardship, oftentimes leading to PTSD, i.e., victims of trafficking, rape, underage women, sufferers of acute or chronic conditions, and sole family carers. The experiences encountered informed curriculum development for midwives and other PC professionals. Interprofessional training for integrated perinatal care delivery was developed for and delivered in three phases, i.e., detection of pregnancy (GP coordination), care during pregnancy (midwive coordination), and support after birth (social worker coordination), with special modules developed in a participatory manner on: migration status and policies, maternity care for MAR women, and communication and culturally sensitive practices.

Conclusions:

Training midwives and other PC professionals along with members of MAR communities in the MPS role was identified to be a key element to efficiently support women and their families, to propagate key perinatal and public health messages, and to advocate for the rights of MAR women to ensure access equity to quality care in a highly responsive manner. ORAMMA's tools are available in easily accessible platform online.

Key messages:

- ORAMMA developed multilingual material to meet the needs of PC professionals and of MAR women, in an innovative manner and with high relevance for cross-border knowledge transfer.
- ORAMMA addressed key aspects in delivery and access, focusing on cultural awareness and communication; its relevance extends well beyond perinatal care to improved family outcomes and public health.

The factors affecting response rate in survey on well-being among people with foreign origin

Eero Lilja

E Lilja[1]*, A Seppänen*[1]*, H Kuusio*[1]
[1]National Institute for Health and Welfare, Helsinki, Finland
Contact: eero.lilja@thl.fi

Background:

Previous population surveys among people with foreign background (PFB) in Finland have had successful response rates (62%-66%) when using mainly face-to-face interviews. A cross-sectional population survey (FinMONIK) explored more cost-efficient ways to collect the data on PFB.

Methods:

The data collection was conducted in Finland between May 2018 and January 2019. The random sample consisted of 12 877 (after removing over-coverage) 18-64-year-olds stratified by region. First, a letter containing a link to the online survey with 18 different language options was sent to the participants. After two reminders, the questionnaire was sent twice on paper to the non-respondents. Finally, supplementary phone interviews were carried out by multi-lingual interviewers. All the participants were able to enter in a draw to win gift cards.

Results:

The response rate (RR) for the online survey was 34%. RR was highest for those who had lived in Finland 5 years or less (43%) and lowest among the divorced (23%) and Estonians (27%). The paper questionnaire was mostly preferred by older age groups, increasing the RR of 40-64 year-olds from 31% to 48%. Telephone interviews increased the RR by five percent points, thus making the final RR for the survey 53%. Persons born in the EU and North-America responded the most frequently (58%) whereas RR was lowest amongst the Sub-Saharan African origin migrants (47%). RR was particularly low (42%) for those who had moved to Finland at ages 0-6.

Conclusions:

In surveys conducted amongst PFB, relatively good response rates can be obtained by using alternate methods for gathering data instead of costly and time-consuming face-to-face interview. Age and marital status seemed to affect the preference of survey format. The overall RR varied by country of origin.

Key messages:

- A good response rate can be obtained without face-to-face interviews in migrant population surveys.
- Migrant population surveys can be conducted more efficiently by combining a variety of methods.

Social Gradients in Alcohol Use Disorders with and without Depression: Immigrants vs Norwegians

Marja Leonhardt

M Leonhardt[1], *D Shawel Abebe*[2,1]
[1]Norwegian National Advisory Unit on Concurrent Substance Abuse and Mental Health Disorders and Mental Health Division, Innlandet Hospital Trust, Brumunddal, Norway
[2]Department of Nursing and Health Promotion, Oslo Metropolitan University, Oslo, Norway
Contact: marja.leonhardt@sykehuset-innlandet.no

Background:

The social gradient in health runs from top to bottom of the socioeconomic spectrum. Poverty is associated with poor health and problematic unhealthy behaviors. Depression is strongly associated with social inequalities, while alcohol use disorders are not necessarily associated with a low socio economic status. Immigrants often have a lower social economic status than the host population. Research regarding alcohol use disorders, depression and a social gradient among immigrants is scare. The present study explores social gradients in persons with alcohol use disorders with and without depression and examines potential discrepancies between immigrant and native Norwegian patients receiving public specialist health care.

Methods:

Data of 2.4 million native Norwegians and 468.496 immigrants, registered in the national mandatory Norwegian Patient Register and population data from Statistics Norway were analyzed. ICD 10 main diagnoses were used to identify patient groups - at least diagnosed once during 2008 - 2016. Immigrants had been pooled into 5 world regions. Logistic regression models have been applied to show associations between socio demographics/regions and alcohol use disorders and/or depression.

Results:

African (OR = 0.35; 95%CI:0.27-0.44) and Asian (OR = 0.23; 95%CI:0.16-0.32) immigrants had a lower risk of developing alcohol use disorders with depression than Western Europeans (OR = 0.76; 95% CI:0.60-0.98), using native Norwegians as a reference. In general, persons with a lower socioeconomic status are more often affected of alcohol use disorder only (OR = 3.77; 95%CI:3.64-3.91) than with alcohol use disorder and concurrent depression (OR = 3.52; 95%CI:3.25-3.83).

Conclusions:

To detect possible deficits in patient care, knowledge of social gradients in a marginalized group such as persons with alcohol use disorders and/or depression is essential. This may contribute to targeted and individualized health care- regardless of immigrant status.

Key messages:

- The risk of developing alcohol use disorders with depression varies between immigrants according to their origin.
- Persons with a lower socioeconomic status are more often affected of alcohol use disorder only than with alcohol use disorder and concurrent depression.

Sustained virological response to Do hepatitis C DAA treatments in migrants and non-migrants groups

Tchadine Djaogol

T Djaogol[1], *H Fontaine*[4], *M Baudoin*[1,2], *C Protopopescu*[1,2], *F Marcellin*[1,2], *C Dorival*[5], *M Bourlière*[6], *E Delarocque-Astagneau*[7], *F Carrat*[3], *P Carrieri*[1,2]
[1]SESSTIM UMR 1252, Marseille, France
[2]ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France

[4]AP-HP, Hôpital Cochin, Unité d'Hépatologie, Paris, France
[5]Sorbonne Université, Institut National de la Santé et de la Recherche Médicale, Institut Pierre Louis d'Epidémiologie et de Santé Publique, Paris, France
[6]Department of Hepatology and Gastroenterology, Hôpital Saint Joseph, P, France
[7]UMR1181, Biostatistique, Biomathématique, Pharmaco-épidémiologie et Maladies Infectieuses (B2PHI), Institut Pasteur, Inserm, Université de Versailles-Saint-Quentin-en-Yvelines (UVSQ), Paris, France
Contact: tdjaogol@gmail.com

Background:

Although the efficacy of direct acting antivirals (DAA) against hepatitis C (HCV) has been widely proven, data lack on their effectiveness in the most vulnerable groups. In France, despite universal health coverage, migrants cumulate vulnerabilities including delays in screening that may affect both access to care and treatment effectiveness. We tested whether DAA-treated migrants had sustained virological response (SVR) rates comparable to not-migrants.

Methods:

We used data collected in chronic HCV-infected patients of the ANRS CO22 HEPATHER cohort, receiving a first treatment with DAA, with follow-up from 2012 until 2022. SVR was measured by PCR, 12 weeks after the end of treatment. The main covariate was a 4-category variable comparing migrants and non-migrants, with or without other vulnerability conditions (including drug use, unhealthy alcohol use, living in poverty, being a man who have sex with men). We used a Poisson regression model to assess the relationship between this covariate and SVR after adjustment for significant predictors and potential confounders.

Results:

The analysis included 5,080 individuals, of which 17% classified as migrants with at least one vulnerability, 10% as migrants with no vulnerability, 39% as non-migrants with at least one vulnerability and 35% as non-migrants with no vulnerability. Median [IQR] age was 57 [51-65] years, 56% of individuals were men, and 96% had SVR. The multivariable analysis showed no significant difference between the 4-category covariate and SVR. In addition, we found that SVR rates increased steadily during follow-up.

Conclusions:

This is the first analysis exploring differences in SVR rates among migrants and not-migrants. The lack of significant differences found despite the power of the study suggests that migrants respond to DAA treatment as well as any other group of HCV-infected patients. These data can help advocating better screening and access to treatment for HCV-infected migrants in France.

Key messages:

- No significant differences were observed between migrants and non-migrants in terms of effectiveness of DAA treatment.
- These findings can help improving access to HCV care for migrants.

Factors related to emigration self-efficacy among university students in Slovakia

Bohuš Hajduch

B Hajduch[1], *O Orosová*[1]
[1]Faculty of Arts, Pavol Jozef Šafárik University, Košice, Slovakia
Contact: hohus.bajduch@gmail.com

Background:

Emigration self-efficacy (ESE) as the confidence in onés ability to successfully handle migration is an important characteristic of a migrant. We hypothesized that positive migration experience might increase ESE. We also explored whether personality factors such as extraversion, openness to experience, neuroticism, conscientiousness and agreeableness might be related to the ESE of young people (under 30 years old) in

Slovakia. The moderation effect of gender in the relationship between the independent variables and ESE was also tested.

Methods:

The sample consisted of 474 students from Slovakia (76.8% women, M = 22.4, SD = 2.13) all participating in the Student Life Cohort Study (SLiCE 2016) which focuses on the emigration intentions and risk behaviour of university students. The data were collected via an online survey. Standard multiple regression was used and the analysis was adjusted for gender.

Results:

The model explained 23.1% of the variance in ESE. An evaluation of migration experience was found to make the largest unique contribution in explaining ESE ($\beta = 0.317$, $p\alpha<0.001$). Regarding personality factors, only neuroticism was found to be significantly related to ESE ($\beta=-0.155$, $p\alpha<0.05$). The main effect of gender was also significant ($\beta=-0.179$, $p\alpha<0.001$) with males scoring higher in ESE although the moderation effect of gender in the relationship between the independent variables and ESE was not significant.

Conclusions:

This study provides an insight into the role of personality factors and evaluation of migration experience in relation to ESE among Slovak university students. Future research may focus on a deeper exploration of the other factors affecting neuroticism, as reducing the level of neuroticism could be beneficial in experiencing healthier and safer migration and adaptation process.

Key messages:

- A more positive migration experience and lower level of neuroticism are related to emigration self-efficacy among university students in Slovakia.
- Emigration self-efficacy is an important factor of healthy migration.

Bridging Generations: Sharing stories from the past with the future

Maryellen Brisbois

M Brisbois[1], H Silva[2], R Soares[2], L Cabral[2], H Canasta[1], A Feno[1], A Santos[2]
[1]Community Nursing, University of Mass Dartmouth, Dartmouth, USA
[2]School of Health, University of the Azores, Ponta Delgada, Portugal
Contact: mbrisbois@umassd.edu

Background:

As the immigration population continues to grow; little is known about this phenomenon from the immigrants' perspective. In recent years, nurses have embraced narrative inquiry to better understand the human experience. When relaying their stories, vulnerable groups legitimize their behavior, share their emotional experiences, and amplify their voices that may have otherwise remained silent.

Objective:

Eight elderly Portuguese women who immigrated to the United States (US) were interviewed about their experience of immigration by nursing students from Portugal and U.S., as part of a student exchange. The objective of this project was to better understand the impact of immigration through narrative inquiry.

Results:

On average, the women lived in the US for approximately fifty years; immigrating in their early twenties. Most women arrived alone or accompanied by spouse and/or children. Their first memories were related to snow, and solitude of being in a new country. The participants attended classes to obtain documents or learn English. All worked in the textile industry; their greatest accomplishment was buying their own house. Challenges faced were related to language and difficult jobs. Overall, they had no regrets except in leaving family members behind. Their message to the students was that love and family are most important in the world. Students were able to realize emigration and immigration from their respective countries.

Conclusions:

Rich descriptions provided an in-depth understanding of the details of the women's experience. Student nurses gained valuable skills and knowledge to understand the impact of immigration among Portuguese women using narrative inquiry.

Key messages:

- The use of narrative inquiry proved to be a valuable method to interview Portuguese immigrant women.
- Every immigrant has a unique narrative to share that allowed for nursing student's appreciation of the experience across generations.

Health-Related Quality of Life in resettled refugee youth

Cecilie Dangmann

C Dangmann[1,2], P A Andersen[2], Ø Fjeld-Solberg[3], A K Steffenak[1,2], S Høye[1,4]
[1]Faculty of Health and Social Sciences, Inland Norway University of Applied Sciences, Elverum, Norway
[2]Faculty of Health and Social Sciences, Inland Norway University of Applied Sciences, Lillehammer, Norway
[3]Forced Migration and Refugee Health, Norwegian Centre for Violence and Traumatic Stress Studies, Oslo, Norway
[4]Faculty of Nursing and Health Sciences, Nord University, Bodø, Norway
Contact: cecilie.dangmann@inn.no

Aim:

Millions have fled from the Civil unrest in Syria and half of these are children and youth. Although they are a population with elevated risk for health problems due to adverse pre-migratory and post-migratory experiences, few studies have explored their Health-Related Quality of Life (HRQoL). This is considered a fundamental construct in public health and might provide complementary descriptions of their health and wellbeing after resettling in a new country.

Methods:

A cross-sectional survey of 160 Syrian youth aged 13-24 years recently resettled in Norway, was carried out in 23 schools. Using KIDSCREEN-27, results from five dimensions of HRQoL (physical and psychological wellbeing, parental relations, school environment and friends) was compared to norm populations and analysed with associated sociodemographic factors and war related adverse events.

Results:

Preliminary results indicate that for most participants the overall HRQoL was good, but lower in the dimensions for physical and psychological wellbeing and friends than in norm populations. Satisfaction with parental relations and the school environment was high and the main contributors to a positive HRQoL in the participants. Age and number of reported Stressful Events had the greatest impact of all the the included variables, but all correlations were small to moderate and therefore accounted for little of the total variance.

Conclusions:

The findings suggest that HRQoL is a relevant and non-invasive measure for refugee youth. Interventions focussing on general psychological wellbeing and networks could be beneficial for the group, and need to be explored. These interventions could potentially be based in schools or in family work, to benefit from these being seemingly safe environments for the majority of the group.

Key messages:

- Health Related Quality of life in young Syrian refugees was good, but lower in the dimensions for friends and psychological wellbeing than for norm populations.
- Satisfaction with parental relations and school environment was high among the Syrian youth and the main areas that contribute to a positive Health Related Quality of Life.

Health and behavioral changes among international students at the University of Georgia

Mariam Lobjanidze

M Lobjanidze[1], *D Rada-Fernandez de Jauregui*[2,1], *R Kvanchakhadze*[1]
[1]Public Health and Healthcare Management, The University of Georgia, Tbilisi, Georgia
[2]Preventive Medicine and Public Health Department, The University of the Basque Country (UPV/EHU), Vitoria-Gasteiz, Spain
Contact: m.lobjanidze@ug.edu.ge

Background:

During last decade the number of international students is rising not only in developed, but in developing countries. In this matter, Georgia is not an exception. In 2006-2016, country enrolled more than 13 000 International students in 127 English language programs in 33 Higher Education Institutions. Study aimed to investigate health and lifestyle changes among international students of one of the largest universities of Georgia.

Methods:

A cross-sectional survey was carried out in 2018 by web-based anonymous questionnaires among international and local students at the school of health sciences (UoG). Data was obtained on self reported physical health conditions, dietary patterns, physical Activity, sleep, study routine, smoking, alcohol and drug consumption, sexual life and stress factors.

Results:

112 local and 50 international students of UoG from more than 10 countries participated in online survey. 77% of local and 37% of international participants were female. Students reported health problems related to digestion (43% local, 23% int), musculoskeletal system (20% local, 33% int), sleep (62% local, 43% int), skin, hair and nail (29% local -28% int) after attending university. 22% of international students reported to start smoking after coming to Georgia and 50% evaluated own stress level as 7 out of 10 point scale. Moderate positive correlation was found between stress and health problems among international students ($r = 0.447$, $p = 0.005$). As a main stress factors international students indicated study routine, homesickness, sleep and financial difficulties.

Conclusions:

Survey results indicate that social and physical environment changes as well as busy time schedule can be led to different health problems, and lifestyle changes among international students of UoG. Hence, health promotion campaigns, even among students of health sciences might play supportive role.

Key messages:

- 22% of international students of UoG reported to start smoking after coming to Georgia and 50% evaluated own stress level as 7 out of 10.
- There is a need of health promotion campaigns, even among students of health sciences.

Factors influencing the migration intention of dental and medical graduates in developing countries

Sara Hajian

S Hajian[1], *MH Khoshnevisan*[1,2], *Sh Yazdani*[3], *MP Jadidfard*[1]
[1]Community Oral Health, School of Dentistry, Shahid Beheshti University of Medical Sciences, Tehran, Iran
[2]Preventive Dentistry Research Center, Research Institute of Dental Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran
[3]Medical Education, School of Medical Education, Shahid Beheshti University of Medical Sciences, Tehran, Iran
Contact: hajiansara@yahoo.com

Background:

Migration of skilled health workers could result in shortage of human resources and rising inequalities in service provision in source countries. To date, most of relevant papers are focused on rate and reasons of migration while the need for conducting studies on modelling of factors is more vividly felt. The aim of this review was to determine the factors influencing the migration decisions of medical and dental graduates migrating from developing countries and to introduce a practical conceptual framework for health worker migration.

Methods:

Electronic databases PubMed, Google Scholar and relevant Journals were systematically searched for English language publications from January 2009 to April 2019. The inclusion criteria were: 1) article stated factors affecting migration decisions of medical doctors and/or dentists, 2) the source country in the study was a developing country, 3) participants' primary qualification country was in a developing country,4) the study used primary data both qualitative or quantitative.

Results:

The search identified 814 articles from which we included 23 full-text studies after applying eligibility checklist. Push and pull theory was the most popular model to describe the migration driving factors. Poor socio-economic situation, political instability, lack of professional and educational opportunities together with family concerns found as strong common push factors that perpetuate migration. The most influencing pull factors were desire for better quality of life, career and training opportunities and financial gain.

Conclusions:

Despite the fact that health workers migrate for different reasons, they follow a same route for decision to stay or leave their own countries. Un-fulfillment of expectations in mother land in addition to media reconstructed reality of life in foreign land can develop a positive attitude for migration Which should be considered before weighing up the push and pull factors of both sides.

Key messages:

- A better understanding of the migration motives of health professionals will help health authorities to improve their workforce recruitment and retention strategies and health service planning.
- Our simple yet comprehensive framework can mainly identify the development of migration desire through combining different models and concepts of migration, behavioral change, values, needs and so on.

The impact of precarious employment on the health and wellbeing of immigrants: a systematic review

Monique Lhussier

M Muoka[1], *M Lhussier*[1]
[1]Faculty of Health and Life Sciences, Northumbria University, Newcastle upon Tyne, UK
Contact: monique.lhussier@northumbria.ac.uk

Background:

Migration and precarious employment are social determinants associated with adverse health outcomes. In the United Kingdom, migration policy and labour market characteristics mean that migrants are often engaged in precarious work. We synthesise evidence on the experiences of migrants and explore the effects of precarious employment on their health and wellbeing.

Methods:

Electronic databases were searched for peer-reviewed qualitative studies describing the experiences of United Kingdom migrants in precarious employment. Title and abstracts were screened, followed by full text screening using pre-specified inclusion and exclusion criteria. Data on employment experiences and effects of working conditions on physical and mental health and perceived wellbeing were extracted. The Centre for Reviews and Dissemination (2009) framework was used to conduct a narrative synthesis.

Results:

Out of 1577 unique citations, 5 met our inclusion criteria. All included studies reported negative outcomes on physical and mental health. 2 reported positive or negative outcomes for perceived wellbeing depending on pre-migration experience. Musculoskeletal pain, exhaustion, anxiety and depression were commonly reported effects of precarious employment. Communication difficulties and over qualification were identified as migrant specific factors influencing health outcomes.

Conclusions:

Stress response theories and risk factors associated with occupational injury explain how employment specific factors influence health. Extrinsic factors such as immigration policies, pre-migration experience, responsibilities in home country and acculturation mediate precarious employment effect on health.

Key messages:

- Migrants feel isolated in precarious employment and are vulnerable to negative mental and physical health impacts.
- Broader migration related policies impact on experiences of employment and health.

Combined sexual prevention targeted to LGBTI+ migrants: between 'outdoor' and 'indoor' hospial

Cyriac Bouchet-Mayer

C Bouchet-Mayer[1], *A Sow*[1], *C-P Kouadio-Sankadio*[1], *A Peltier*[1], *F Héteau*[1], *F Legrais*[2,3], *M Shelly*[1,2]
[1]Public Health Association, AREMEDIA, Paris, France
[2]Centre Gratuit de d'Information de Dépistage et Diagnostic, University Hospital Saint-Louis-Lariboisière-Fernand Widal (AP-HP), Paris, France
[3]Public Health Department, University Hospital Saint-Louis-Lariboisière-Fernand Widal (AP-HP), Paris, France
Contact: cyriac@aremedia.org

Issue:

It is estimated that there are about 10,000 HIV-positive and undiagnosed people in Île-de-France (French region). They are composed of 70% men, 40% of whom are MSM and 40% of sub-Saharan African migrants. A bridging process has been designed by the Public Health association AREMEDIA and developed in partnership with Fernand-Widal Hospital's testing center, to reach underserved populations. From March 2018, a screening test session for sexually transmitted infections (STIs) is taking place weekly in the hospital walls. This action is dedicated to the population of ARDHIS association, which accompanies more than 1,000 people each year, seeking asylum because of their sexual orientation or gender identity.

Description of the problem:

Despite the promotion of this 'indoor' targeted consultation via ARDHIS volunteers and directly to asylum seekers during occasional community events, the consultation only allowed the screening of 23 people in 4 months. It has been decided to carry out screening 'outside the hospitals walls', where the people are, in order to promote the return of results, treatment, access to PrEP, HBV vaccination at the weekly indoor hospital consultation. ''Community health relays'' training together with the development of phone contact procedures were developed to facilitate the access to the indoor consultation.

Results:

The methodology made it possible to double the average number of consultations over the following 5 months from 5 to 10 consultations per 3-hour slot, not counting PrEP appointments and vaccines, which averaged 6 per session. By the end of 2018, 261 people were screened, 23 had a PrEP treatment and many were vaccinated. As the scheme continues to develop, the results from January to July 2019 will be reported.

Leçons:

- To reach the most at risk populations, specific public health approaches are needed, taking account the context and representations of the target populations.
- Community involvement has proven to be effective.

Key messages:

- To fight HIV, innovative devices are needed to reach targeted populations.
- This has allowed hundreds of LGBTI asylum seekers to be screened and a significant number to receive preventive treatment.

Experiences of specialist social workers for asylum seeking patients at a large Swedish hospital

Veronica Svärd

V Svärd[1,2], *M Nilsson*[2,4], *E Sernbo*[3]
[1]Division of Insurance Medicine, Karolinska Institutet, Stockholm, Sweden
[2]Function Area Social Work, Karolinska University Hospital, Stockholm, Sweden
[3]Department of Social Work, University of Gothenburg, Gothenburg, Sweden
[4]Division of Family Medicine and Primary Care, Karolinska Institutet, Stockholm, Sweden
Contact: veronica.svard@ki.se

Background:

In 2016, the Karolinska University Hospital introduced a one-year-project with a mobile team of five asylum social workers (ASW), specializing in migration. This study evaluates the ordinary hospital social workers (HSW) experiences of introducing ASWs for asylum seeking patients.

Methods:

Descriptive analysis was made of answers from a questionnaire sent to all 144 HSW at the hospital (57% response rate). Qualitative content analysis was made of written comments.

Results:

Of the HSWs, 51% always and 29% sometimes contacted an ASW in relation to asylum seeking patients. Of those who contacted an ASW, 74% stated that the ASWs increased the efficiency of care of asylum seeking patients. 65% agreed that ASWs had an improving effect on the quality of encounters between staff and asylum seekers. Also, 67% agreed that the ASWs off-loading function improved the HSWs working conditions. Even though the ASWs were working at two hospitals located in different parts of the region, 78% of HSWs found them to be available. The main reason to not always contact an ASW was that it was not necessary in the specific case (55%). A majority (66%) reported increased knowledge about asylum processes as an outcome of introducing the ASWs at the hospital. This was also highlighted in the written comments, where ASWs detailed and updated knowledge as well as established contacts with e.g. the Swedish Migration Board was emphasized. ASWs specialist competence enabled patients to quickly receive legally correct and accurate information, which decreased worries among patients as well as staff members.

Conclusions:

The HSWs described the ASWs as being important to patients as well as to staff. The ASWs improved the quality of encounters between staff and asylum seekers and strengthened the patient's right to health and social care. The HSWs also reported an off-loading function, improving the working conditions and the over-all efficiency of care.

Key messages:

- The HSWs found that the ASWs increased the efficiency of care and quality of encounters between staff and asylum seekers.
- ASWs detailed knowledge and established external contacts enabled patient to receive accurate information quickly, which decreased worries among both patients and staff members.

Syndromic infectious disease surveillance of refugees in Greece: a mixed methods analysis

Julia Graef

J Graef[1], *M Omar*[2], *A Abbara*[1]
[1]School of Public Health, Imperial College London, London, UK
[2]LSHTM, London, UK
Contact: jg5715@ic.ac.uk

Background:

An estimated 1,174,140 refugees have migrated into Greece, a main entry point for refugees into Europe, since 2014. Their infectious disease profile is monitored by a national-level ad-hoc syndromic surveillance system in refugee-migrant reception centres. The utility of this system is explored to contribute evidence to and improve syndromic surveillance in European refugee responses.

Methods:

Proportional morbidities, numbers of cases and signals, cases above expected numbers, of 14 syndromes are collated from weekly reports between 2016-2019, graphed and analysed in the context of the humanitarian response. Semi-structured key informant interviews are conducted and thematically analysed.

Results:

Between 20.06.2016 and 17.02.2019, 36358 cases and 116 signals occurred. Public health responses resulted and there were no significant outbreaks. On average 5% of all consultations in centres were on infectious syndromes. Respiratory infections with fever (57%), gastroenteritis (22%), suspected scabies (13%) and rashes with fever (5%) were most commonly reported. Every week, between 68-100% of 25-58 participating centres completed reporting adequately. 6 informants reported on their syndromic system user experience. The system's benefits, providing information and safeguarding refugees, outweighed harms. Data was timely and complete, but likely under-reported for common conditions. Poor living conditions and inter-agency coordination complicated reporting and public health responses.

Conclusions:

Infectious burdens and trends were provided by the system and allowed for timely responses. Data quality was adequate. The system was valuable and feasible to informants. The set-up of the humanitarian response, inadequate ownership and poor coordination of authorities reduced the system's utility.

Key messages:

- Syndromic surveillance is useful for monitoring refugee infectious health.
- Structural barriers need to be resolved to improve systems' data and user experience.

The influence of culturalisation on GP consultations and in research on GP care

Alex Stern

A Stern[1]*, O Razum*[1]

[1]Department of Epidemiology and International Public Health, School of Public Health, Universiy of Bielefeld, Bielefeld, Germany

Contact: a.stern@uni-bielefeld.de

Background:

General practitioners (GPs) have a gatekeeping function in the healthcare system. Research shows that patients of Turkish origin in Germany manage to access specialist care less often than non-immigrant patients. Underlying could be problems related to interactions with the GP. Focusing on interaction instead of individual patients' characteristics might help identifying underappreciated barriers in health care.

Methods:

We conducted a scoping review to identify research on interaction-related aspects of GP consultations of people of Turkish origin. Goffman's interactional theory was used for operationalisation. Analysis focused on the process of consultation from the perspectives of patients, GPs, and interpreters. Additionally, noticeable issues in researchers' perspectives on migrants' utilization of health care were identified.

Results:

Patients of Turkish origin expect similar professional performances from their GPs as patients without a migration background. If informal interpreters take part, misinformation might remain unrecognised. Frequently, GPs experience insecurity, which sometimes results in lower empathy and prejudice-based, unprofessional reactions or misdiagnoses. Researchers' interpretations refer partly to unfounded explanations such as a homogeneous Turkish culture or somatization tendencies of Turkish patients.

Conclusions:

Difficulties in GP care of patients of Turkish origin, and access barriers to specialist care, arise less from culture-bound performances of these patients as from culturalising expectations and performances of GPs. Researchers often show similar expectations and interpretations. Such culturalising interpretations should be avoided in future research.

Key messages:

- Difficulties in GP care of patients of Turkish origin, and access barriers to specialist care, arise less from culture-bound performances of these patients as from culturalising expectations of GPs.
- Future research should avoid culturalising interpretations.

Ethnic differences in participation in diabetes education programmes

Anne Juul

A Juul[1,2]*, C Glümer*[3,4]*, SS Jervelund*[2]*, NF Hempler*[1]

[1]Diabetes Management Research, Steno Diabetes Center Copenhagen, Gentofte, Denmark

[2]Department of Public Health, University of Copenhagen, Copenhagen, Denmark

[3]Center for Diabetes, Copenhagen Municipality, Copenhagen, Denmark

[4]Department of Medicine and Health Technology, Aalborg University, Aalborg, Denmark

Contact: anne.mette.juul.andersen@regionh.dk

Background:

Immigrants from non-Western countries have a higher prevalence of type 2 diabetes. In addition, immigrants have an increased risk of developing diabetes complications, compared with the general population. Diabetes education programmes facilitate essential knowledge and skills that enable people to manage their condition in daily life. However, fewer immigrants attend and complete diabetes education compared with the general population. The aim of this study is to explore what characterises those who decline and accept participation in diabetes education in relation to ethnicity, household composition and diabetes burden in the family.

Methods:

The study population consisted of adults with type 2 diabetes referred to a municipal diabetes centre (n = 1819). Individual medical record data was linked to national registry data. Descriptive statistics and logistic regression models were applied.

Results:

Preliminary results showed that 23% of individuals from the study population participated in diabetes education. We found no overall differences in participation rates between the general population and non-Western immigrants (24% vs. 18%, P = 0.12). However, when examining the immigrant groups by language (Arabic, Urdu and Turkish), the results indicated a non-significant tendency: Urdu speaking groups' participation was similar to the general population (24%), whereas Arabic and Turkish speaking groups had lower participation rates (17% and 11%, P = 0.25/0.40).

Conclusions:

The results suggest that there are differences in participation between some immigrant groups and the general population. Increased knowledge about which mechanisms affecting participation in diabetes education programme is required to ensure equal access. Further studies and analyses will explore how immigrants' social relations enable and/or hamper participation in diabetes education and investigate which factors can be changed to improve participation rates.

Key messages:

- There are differences in participation in diabetes education programmes across different ethnic groups, which suggests a need for in-depth analysis into which mechanisms that affect participation.
- The results will be used to give input for future practices that can increase immigrant's participation and retention in diabetes education programmes.

Country Assessments: Identifying gaps in policy and practice to address equity in health for migrants

Charlott Nordström

C Nordström[1], *D Ingleby*[1], *S Dias*[3], *J Magnus*[2], *B Kumar*[1]
[1]Unit for Migration and Health, Norwegian Institute of Public Health, Oslo, Norway
[2]Faculty of Medicine, University of Oslo, Oslo, Norway
[3]National School of Public Health, NOVA University of Lisbon, Lisbon, Portugal
Contact: charlott.nordstrom@fhi.no

Issue:

The Joint Action on Health Equity in Europe (JAHEE) aims to address inequities in health across all groups. Work Package 7 Migration and Health (WP7) includes 13 partner countries and focuses on health inequities affecting the migrant population. The project started out by developing Policy Framework for Action (PFA), intended to form the basis for exploring opportunities for appropriate actions in the three-year implementation period of the action. The PFA formulated a 'road map' encompassing six priorities identified in 22 'soft policy' documents that have been published by international / governmental organisations since 2007. It also discussed the state of the art in research on the causes of particular inequities undermining migrant health, as well as the measures that can be taken to tackle them.

Description of the problem:

The main objective of the Country Assessments (CAs) is to identify the best opportunities (entry points) for developing country-specific actions. From this list, actions will be selected and implemented that are feasible within the constraints of JAHEE. The CAs will provide the information partners need in order to make informed choices. The assessments will indicate where the most serious inequities lie, what causes them, and what can be done about them. The CA Template was based on the PFA, reviewed by the Expert Group and then piloted in two countries (Norway and Italy) in March 2019. The 13 partners participating in WP7 are currently carrying out their assessments, which will be completed by July 2019.

Results:

An overview of the main results of the CAs will be presented at the conference.

Lessons:

Developing and piloting the Country Assessment Template has been participatory, with necessary revisions on the basis of experience. Completing these assessments for each participant is in itself is the first step towards action. Participants create an overview of available data, experiences and gaps in their countries.

Key messages:

- The Country Assessment Template is a tool that enables partners to take stock of the situation in their country.
- Analysis of data from the assessments will enable countries to make an appropriate choice of actions.

Characteristics of specialist consultations regarding immigrant patients at a large Swedish hospital

Veronica Svärd

V Svärd[1,3], *E Sernbo*[4], *M Nilsson*[2,3]
[1]Division of Insurance Medicine, Karolinska Institutet, Stockholm, Sweden
[2]Division of Family Medicine and Primary Care, Karolinska Institutet, Stockholm, Sweden
[3]Function Area Social Work, Karolinska University Hospital, Stockholm, Sweden
[4]Department of Social Work, University of Gothenburg, Gothenburg, Sweden
Contact: veronica.svard@ki.se

Background:

After an increased number of asylum-seeking patients, the Karolinska University Hospital in 2016 introduced a one-year-project with five asylum social workers (ASW). This study analyzes the characteristics of patients, issues and performed tasks.

Methods:

The data consists of five months anonymized case documentation of ASWs direct patient contacts and documented telephone consultations with staff. Descriptive statistics and qualitative content analysis were made.

Results:

Of direct patient contacts, 56% were with asylum seekers, 7% undocumented, 7% EU citizens and 30% had various forms of migration status. Tasks consisted of 39% external cooperation, 15% writing certificates, 20% applying for e.g. social assistance for patients' basic needs.

Analysis of telephone consultations with staff showed that 24% concerned patients with unclear migration status, 17% undocumented, 14% asylum seekers, followed by various forms of migration status. The issues related to patient rights (17%), housing and discharge problems (17%), subsidized health care (11%), costs for care (10%), social assistance (8%) and national registration and establishment (8%). Performed tasks by ASWs were legal advice (19%), referral for further management (19%), advice about cooperation with e.g. the Swedish Migration Board (14%), costs for health and social care (13%), social support (11%), health care administration (10%), application for visa or passport (8%) and the right to subsidized health care (7%).

Conclusions:

ASWs performed tasks concerning cooperation and advisement regarding care-planning and legal concerns, helping both patients and staff. Staff were often insecure about immigrant patient's legal status and right to health and social care. To optimize support to staff regarding asylum-seeking patients, it is recommended to use a broader definition of migration status to include unclear cases.

Key messages:

- The hospital staff were often insecure about immigrant patient's legal status and consultation should thus address various forms of migration status among patients.
- The hospital staff needed consultation regarding legislations, discharge, housing, social assistance and costs for and right to health and social care.

Optimum control of TB in the EU by addressing migrant health effectively in an interconnected world

Margo Koster

DM Koster[1], *AJ Bootsma*[2]
[1]Public Health, Topicus.Healthcare, Deventer, Netherlands
[2]Team Safety, GGD GHOR Nederland, Utrecht, Netherlands
Contact: margo.koster@topicus.nl

Worldwide, tuberculosis is one of the top 10 causes of death. Although most EU/EEA countries are low-incidence, TB remains a public health issue. In this region, TB predominantly affects vulnerable populations, including migrants (ECDC/WHO, 2019). Since migration has been increasing over the last several decades, the health needs are considerable and merit great attention for several reasons. First, migrants have a right to health. Second, health promotion and disease prevention among migrants contributes to overall public health. Last, healthy migrants contribute to positive development outcomes (WHO, 2016) (IOM, 2017).

In order to meet the health needs of migrants, prevention is an important step. Part of preventive care is detecting illness at an early stage (for example by screening), so that treatment can be introduced when it works best (WHO Europe, 2018). However, screening of a population is only beneficial if a positive result leads to effective actions independent of geographic location (Jackson, 2017).

So, how does one facilitate a fluid care pathway for TB-elimination? In the Netherlands, the Community Health Services (GGDs) carry out TB-control non-geographically. All 25 GGDs use iTBC, a nationwide, integrated platform that supports and connects all TB processes, independent of place and time. The appropriate TB screening pathway is selected, based on prevalence in country of birth, for all migrants resulting in optimized screening, treatment and control. In a PPP between Topicus, the Dutch Association of GGDs (GGD GHOR Nederland) and the Central Agency for the Reception of Asylum Seekers, this process has been automated for asylum seekers. By safely sharing relevant data, migrants can be screened and treated effectively. Resulting in health needs of migrants being met and optimum control of TB in low-incidence countries. The aim is to screen, treat, control and end tuberculosis whilst scaling the Dutch blueprint across the EU/EEA region.

Key messages:

- TB-screening contributes to EU public health if follow-up actions are facilitated non-geographically.
- The Dutch blueprint for TB-control shows how migrant health needs are met in an interconnected world.

Family conflict mediates the relationship between past violence and wellbeing among female refugees

Leah Okenwa Emegwa

L Okenwa Emegwa[1,2], *F Saboonchi*[1,3]
[1]Health Sciences, The Red Cross University College, Huddinge, Sweden
[2]Occupational and Public Health Sciences, University of Gävle, Gävle, Sweden
[3]Department of Clinical Neuroscience, Karolinska Institute, Stockholm, Sweden
Contact: leok@rkh.se

Background:

Past exposure to violence has been suggested to have a lasting effect on subjective well being (SWB). Similarly, family conflict is another known predictor of SWB. Research shows that refugee women exposed to gender based violence (GBV) before resettlement may also face post-resettlement family conflicts due to socio-cultural factors, changes in social network and migration-based shifting gender roles. This study examines the role of family conflict as a likely mediator between past exposure to violence and SWB among Syrian refugee women in Sweden.

Methods:

A total of 452 women out of a random sample of 1215 Syrian refugee women in Sweden responded to a questionnaire survey in Arabic. Variables include Past violence i.e. exposure to any of torture, physical or sexual violence preflight or during flight before arriving Sweden; Post-resettlement distressing family conflicts i.e. feeling disrespected or unimportant in the family or distressing conflicts; SWB was measured by WHO-5 wellbeing index. Maximum likelihood estimation with Robust standard errors and bias corrected bootstrapped 95% confidence intervals for all estimates.

Results:

Total effect of past violence on SWB was significant (Estimate = -6.63; CI = -12.73 - -0.46). Similarly, family conflicts were associated with decreased SWB (Estimate = -3.80; CI = -5.17 - -2.40), and past violence exposure increased family conflicts (Estimate = 0.57; 0.13 - 1.08). The total effect of violence exposure on decreased SWB was decomposed into a direct and an indirect effect (mediated via family conflicts). The indirect effect via family conflicts was significant (M = -2.19; C1 = -4.30 - 0.59), while decomposing rendered the direct effect non-significant (Estimate = -4.44, CI = -10.51 - 1.52).

Conclusions:

Post-resettlement distressing family conflicts mediate the effect of prior exposure to violence on reduced SWB among refugee women.

Key messages:

- Past violence exposure reduces refugee women's SWB via aggravated family conflicts implying the need for family targeted interventions to improve SWB of female refugees previously exposed to violence.
- Strategies to improve subjective wellbeing among female refugees should include screening for and addressing all forms of previous and ongoing GBV.

Maternal country of birth and in-hospital exclusive breastfeeding: results from a Portuguese study

Cláudia De Freitas

C Lisi[1,2], *C Freitas*[1,3], *H Barros*[1,3]
[1]EPIUnit, Institute of Public Health of the University of Porto, Porto, Portugal
[2]Global Public Health Doctoral Programme, Faculty of Medicine of University of Porto, Porto, Portugal
[3]Public Health and Forensic Sciences, and Medical Education, Faculty of Medicine of University of Porto, Porto, Portugal
Contact: claudia_defreitas@yahoo.com

Background:

Breastfeeding provides benefits for children, mothers, society and the environment. The promotion of optimal breastfeeding, from an early stage in life is, therefore, a public health priority. Infant feeding can be influenced by maternal country of birth. However, studies carried out in European settings point to inconsistent findings. This study aims to compare first day in-hospital exclusive breastfeeding among migrant and native women in Portugal.

Methods:

This study is based on a national project on perinatal health among migrants and natives in Portugal (baMBINO). Out of 39 public maternity units in mainland Portugal, 32 were enrolled. Women aged 18 years old or older with a live birth were recruited. The final sample included 5109 participants (2431 natives and 2678 migrants). Logistic regression was used to assess the association between maternal country of birth and in-hospital exclusive breastfeeding.

Results:

Migrant participants included women from Portuguese-speaking African countries (PSAC) (49,7%), Brazil (18%), Eastern Europe (10.2%), other European countries (9.6%), Asia (5.5%) and other countries (7.0%). No differences were found between migrants and natives, with the exception of women from PSAC who were more likely to exclusively breastfeed during the first day of hospital stay (aOR 1.34 CI95% 1.05-1.72), irrespective of maternal age, education, parity, type of pregnancy, reproductive assistance, tobacco use, gestational age, newborn birth weight, mode of delivery and antenatal care.

Conclusions:

In Portugal, women from PSAC are more likely to exclusively breastfeed their babies during the first day of hospital stay when compared to native women. Strategies to maintain healthy breastfeeding practices in this population are fundamental.

Key messages:

- Women from PSAC are more likely to breastfeed exclusively in the first day after delivery than Portuguese natives.
- They should be supported in the maintenance of optimal breastfeeding practices.

The way towards Migrant Sensitive Occupational Health Care System

István Szilárd

I Szilárd[1], *E Marek*[1], *C Jaksa*[1], *Z Katz*[1]
[1]WHO Collaborating Centre, University of Pécs Medical School, Pécs, Hungary
Contact: istvan.szilard@aok.pte.hu

Background:

The European Union (EU) is facing to the demographic challenge of the ageing society on the one hand and a growing influx of migrants on the other hand. Although since 2008 WHO repeatedly called member states for developing 'migrant sensitive' health care system, still there is a significant shortage in education programs, aiming to build the required human capacity in general, and on the field of occupational health, no any initiative could be observed aiming to empower the service providers with the additional knowledge and skills for facilitating the safe integration of the migrant workforce into the EU's economy.

Objectives:

University of Pécs Medical School (UPMS) has integrated migrant and ethnic minority health - as a new overarching topic - in its optional and/ or regular training program. Occupational health and migration belongs to the compulsory part of the education.

Results:

Each study year more than two hundreds Hungarian, English and German speaking medical students meet at least at a 'sensitization' level the migrant specific aspects of occupational health. In order to improve and - in the need - even extend our program on this field, we have launched a 'quick response' questionnaire research among the students, asking for their opinion, how they see the importance and necessity of this topic within the frame of their medical training. 67 % of the 2012 students highly and/ or mostly agreed with our initiative and 87 % founded the topic very relevant. The majority of the students have expressed that the training has changed their views.

Conclusions:

The endowers of UPMS, as a WHO Collaborating Centre on the field of migration heath training and research are in accordance with WHO newly adopted 'Strategy and action plan for refugee and migrant health and achieves every year several hundreds of medical students who are already 'sensitized' towards the health of migrants.

Key messages:

- EU economy needs migrant sensitive health workforce ont he field of occupational health.
- Medical studens understood the need for migration health training.

Health system resilience – a conceptual and empirical review of health system literature

Katharina Wahedi

K Wahedi[1], *L Biddle*[1], *K Bozorgmehr*[1,2]
[1]Working Group on Social Determinants, Equity and Migration, University Hospital Heidelberg, Heidelberg, Germany
[2]Working Group on Population Medicine and Health Services Research, University Bielefeld, Bielefeld, Germany
Contact: katharina.wahedi@med.uni-heidelberg.de

Background:

The concept of health system resilience has gained popularity in the global health discourse, featuring in UN policies, academic articles and conferences. The term is commonly used to refer to the ability of health systems to respond to challenges. However, there has been no comprehensive overview of how the concept is understood and assessed in health systems research (HSR).

Methods:

We conducted a conceptual and empirical review in 3 databases using systematic methods. Quantitative and narrative synthesis was used to trace the introduction of the concept to HSR, identify relevant definitions and examine its use in research.

Results:

From 4063 references, we identified 96 articles concerned with health system resilience from 2007 - 2017, with a recent increase in literature (45% of studies published since 2016). Many articles take a general perspective; others focus on specific HSR building blocks (e.g. 28% on service delivery) or a particular type of crisis, such as climate change (12.5%) or natural disasters (10.4%). While the concept was developed from the ecological sciences, its meaning has been adapted in HSR, with a shift towards people-centred and process-oriented definitions. We identify three frameworks operationalising resilience: the ''attributes'' framework by Kruk et al. (2017), the ''everyday resilience'' framework by Barasa et al. (2017) and the ''complex adaptive systems'' framework by Blanchet et al. (2017). However, we find a mismatch between these frameworks and how the concept is assessed in 13 quantitative and 8 qualitative empirical studies.

Conclusions:

The HSR literature has converged around a definition of resilience focusing on the system's ability to mitigate ongoing challenges. Differences in emphasis remain, resulting in a variety of operational frameworks. The frameworks require further adaptation and testing in empirical studies to demonstrate the usefulness of ''resilience'' as an analytical category in HSR.

Key messages:

- There is a mismatch between conceptualisation and operationalisation of resilience in the HSR literature.
- Existing operational frameworks of resilience require further adaptation and testing in empirical studies to demonstrate the usefulness of ''resilience'' as an analytical category in HSR.

The benefits and challenges of cash transfer programmes in Greece, with a focus on protection

Florence Rodgers

F Rodgers[1], *A Abbara*[1], *M Omar*[2]
[1]Imperial College London, London, UK
[2]LSHTM, London, UK
Contact: fer14@ic.ac.uk

Introduction:

This qualitative study evaluates cash transfer programmes (CTPs) in forcibly displaced populations, specifically in Greece. There is a focus on protection, encompassing health, gender, child protection and disability. The Greece Cash Alliance, run by the United Nations High Commissioner for Refugees (UNHCR), currently supports 63,853 individuals with cash via a pre-paid card. This study provides insight into challenges encountered by implementers of cash programmes in Greece, and the potential protection issues faced with the changing climate of the cash programme in Greece.

Methods:

A literature review of academic and grey literature and semi-structured key informant interviews with stakeholders including Non-Governmental Organisation and United Nations agency staff were performed. Key informants were identified through purposive sampling. An inductive thematic approach was taken in analysis.

Results:

Main emerging themes included the benefits and challenges of CTPs and their role in protection. Challenges included the mobile, heterogenous population and benefits included economic development in Greece and restored choice to beneficiaries. With regards to protection, informants reported a positive impact through allowing refugees to meet their basic needs and prioritise other needs and CTPs providing consistent access to refugees which could allow identification of protection risks. However, protection was not considered in the design of all CTPs.

Conclusions:

Due to the multi-sectoral nature of the response, there is no standard integration of protection into cash programmes. Cash programming offers unique, regular contact with beneficiaries and chances to identify protection risks that are not always utilised due to minimal staff training in protection. Cash assistance in Greece allows people to meet their basic needs and gives people space and funds to prioritise other needs such as health and education, inherently improving their protection status.

Key messages:

- With cash assistance growing in popularity in humanitarian programming, consideration of protection is important as it can improve the health, safety and dignity of beneficiaries.
- In Greece the cash programme was only designed to meet basic needs but broader effects on protection were seen.

Living conditions, diet and lifestyle of Asian and African undocumented immigrants in Athens, Greece

Syed Ghulam Sarwar Shah

S Awais[1], *SG Sarwar Shah*[2]
[1]Center for Global Public Health Pakistan, Health Services Academy, Park Road, Chak Shahzad, Islamabad, Pakistan
[2]NIHR Oxford Biomedical Research Centre, Oxford University Hospitals NHS Foundation Trust, John Radcliffe Hospital, Oxford, UK
Contact: Sarwar.Shah@ouh.nhs.uk

Aim:

To study the living conditions, diet and lifestyle of undocumented migrants of Asian and African origin living in Athens, Greece.

Methods:

An exploratory study involving a snowball sample of 200 participants who completed a questionnaire survey administered by hand at a non-governmental day-care facility for homeless immigrants in Central Athens. Response rate 60 % (120 / 200 surveys returned).

Results:

Participants were mainly male (96%), aged 20-40 years (84%) and unmarried (61%) with secondary school education (33%). Participants were from different countries of South Asia (81.7%), Middle East (5%) and Africa (11.5%). 26 % of participants arrived in Greece in the last 12 months and travelled on average for 52 days (median 30 days) from their home countries to Greece. The majority of participants (69%) were without a White Card (formerly the Pink Card) for asylum applicants. Their living conditions included homeless / on streets (13%) and living in a shared house (82%) or basement (13%). Participants had access to a kitchen (77%), toilet (77%), water (76%), electricity (78%), heating (53%), refrigerator (76%), TV (68%), computer (43%) and car (7%). Dietary intake and habits revealed that 86% of participants had normal to very good appetite, 52% ate two meals a day and 38% ate breakfast daily but 35% (n = 42) did not eat any breakfast the whole week. The diet included chicken meat (83%), red meat (63%), eggs (60%), white bread (79%), wholemeal bread (33%), rice or noodles (79%), potatoes (74%), vegetables (77%), fresh fruit (66%), dry fruits and pulses (50%) and dairy products (65%). Lifestyle wise, 59% of participants were non-smokers, 13% took recreational drugs and 77% did not allocate any time for daily exercise.

Conclusions:

Undocumented migrants from Asian and African countries take perilous journeys to Europe for a better life but they have very poor social and economic status, which negates the main reasons of leaving their home countries.

Key messages:

- Undocumented migrants from Asian and African countries take perilous journeys for a better life in Europe.
- Undocumented migrants have a very poor social and economic status in Greece.

Perceptions of primary care providers on TB care for migrants: a mixed methods study in Portugal

Sonia Dias

AM Tavares[1], AC Garcia[1,3], A Gama[2], AB Abecasis[1], M Viveiros[1], S Dias[1,2]

[1]Global Health and Tropical Medicine, Instituto de Higiene e Medicina Tropical, Universidade NOVA de Lisboa, Lisbon, Portugal

[2]Escola Nacional de Saúde Pública, Centro de Investigação em Saúde Pública, Universidade NOVA de Lisboa, Lisbon, Portugal

[3]Departamento de Epidemiologia, Instituto Nacional de Saúde Dr. Ricardo Jorge, I.P., Lisbon, Portugal

Contact: smfdias@yahoo.com

Background:

Tuberculosis (TB) is one of the main causes of death worldwide. In 2017, the proportion of TB cases among foreign-born individuals in Portugal was of 19%, and this proportion has been increasing. TB control among migrant populations largely depends on the role of the healthcare providers and their close contact with the patients. We aimed to explore the perspectives of primary care providers on the provision of TB care for migrant patients in Portugal.

Methods:

An online survey and semi-structured interviews were conducted with healthcare providers from primary care settings in Portugal. Overall, 120 participated in the survey, and 17 were interviewed. Data from the survey and interviews were analysed using descriptive statistics and thematic analysis, respectively.

Results:

Many participants (36.9%) considered that migrants arrive at an advanced stage of TB disease, and the main reason referred was migrants' unawareness of the disease and its symptoms. Moreover, half (50.0%) of the providers considered that migrants frequently interrupt treatment, mainly due to their mobility, which causes difficulties in follow-up, and their social isolation that hampers social support. Overall, three main barriers for migrants' access and use of TB care were mentioned: migrants' low socioeconomic status, great bureaucracy required to register at services, and obstacles to benefit from social protection. Providers also suggested more training to improve their cultural competence and updating training on TB care.

Conclusions:

Our study have shown social and economic factors that must be addressed to improve migrants' access and use of TB care. In addition, increased health literacy for migrants and more training initiatives for providers can also contribute to improve TB care for migrants.

Key messages:

- Perspectives from primary care providers in Portugal highlighted social, economic, and administrative obstacles hampering the provision of TB care for migrants.
- With this work we expected to contribute with evidence to improve TB care for migrant patients in Portugal.

Illness behaviour and health needs in migrants characterised by low satisfaction with healthcare

Birgit Reime

B Reime[1], M Tufan[1], E Tkachenko[1], M Sahbaz[1], P Warth[1], C Weidmann[1]

[1]Department of Applied Health Promotion, HS Furtwangen, Furtwangen, Germany

Contact: Birgit.Reime@hs-furtwangen.de

Background:

Previous research shows inequalities in access to and quality of health care for migrants. We aimed to explore in what way individuals with a migrant background, who report different levels of satisfaction with healthcare, differ in terms of illness behaviour, health needs and sociodemographic characteristics.

Methods:

In the rural Southwest of Germany, we conducted a survey with individuals who have a Turkish (n = 217) or Russian (n = 101) background and whom we could contact via cultural centres. Data were analysed using SPSS.

Results:

In the total sample, 47,5% (Turks 53%, Russians 37%) reported always being satisfied with healthcare, 46,9% were sometimes and 5,7% never satisfied. Turks who were not always satisfied with healthcare significantly more often did not have a regular GP, and rarely visited GPs and consultants. They more often reported the need for culture sensitive print material, assistance in applying for ambulant care and culture sensitive treatment in matters such as intimacy and death and dying. Also, they more often demanded accessibility to healthcare providers with the same cultural background compared to Turks who reported more satisfaction with healthcare. Among Russians, not always being satisfied with healthcare was associated with demanding culture sensitive information on ambulant nursing care and demanding more cultural competence in providers regarding the treatment of particular diseases. Gender was not related to satisfaction with healthcare in either group.

Conclusions:

In this sample of migrants from a rural area culture sensitive treatment was reported to be lacking especially in ambulant nursing care and end of life treatment. In view of the increasing heterogenization of society, it is necessary to address the socio-cultural needs of migrants in a home as well as in a hospital context. Therefore, culture-sensitive materials and workshops for health professionals may be useful to complement their own expertise.

Key messages:

- A low level of satisfaction with healthcare may be related to low levels of utilization.
- In this underserved rural area concerns regarding culture sensitive care need to be addressed.

Asylum seekers' healthcare in Italy: policies and practices among different regions

Chiara Milani

C Milani[1], J Bianchi[1], P Bordin[2], S Bortoluzzi[3], V Gianfredi[4], L Mammana[5], L Paglione[6], C Salvia[7], A Corsaro[8]
[1]Department of Health Sciences, University of Florence, Florence, Italy
[2]Department of Public Health and Community Medicine, University of Verona, Verona, Italy
[3]Department of Translational Medicine, University of Piemonte Orientale, Novara, Italy
[4]Department of Experimental Medicine, University of Perugia, Perugia, Italy
[5]Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy
[6]Department of Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy
[7]Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio-Emilia, Modena, Italy
[8]SIMM, Italian Society of Migration Medicine, Rome, Italy
Contact: cloro.plasto@hotmail.it

Background:

The Italian law provides for international protection and universal health-care coverage for asylum seekers (AS). Indeed, they are entitled to be regularly registered at the National Healthcare Service. Before submitting the application for refugee status, medical assistance to migrants is up to local administration. Our aim was to describe and compare policies and protocols regulating AS healthcare from their arrival to their application for refugee status, at national and regional level. Moreover, we investigated the daily healthcare practice addressing potential gaps between policies and practice.

Methods:

The research team is a subgroup of the Inequality working group of the Italian hygiene society and it is composed of public health residents. The research involved also local health workers and other professionals belonging to regional groups of Italian migrant medicine society (SIMM). We collected national, regional and local policies and protocols and we compared them using a specific framework. Furthermore, we achieved a mapping of daily practice implementation at local health organization (LHO) level using a checklist.

Results:

The most relevant findings were that regional policies themselves vary notably from each other and, as regard practices, LHO implement differently the same regional legislation. Furthermore, we found some critical issues: the delayed inclusion in primary care assistance and lack of continuity of care and of a computerized system of recording information.

Conclusions:

The lack of uniformity concerning policies and practices of AS healthcare might also result in unawareness and uncertainty about how to access to healthcare services by migrants. An enhanced cooperation between groups dealing with migrants' issues may lead to avoid variability at the implementation. Finally, a computerized system for data collection might facilitate the continuity of care and the assessment of the real health needs of the AS population.

Key messages:

- It is a priority challenge for health systems to strengthen the interventions aimed at overcoming the linguistic, economic, cultural and administrative barriers to the health services access.
- It is crucial to improve the recording information system to detect the real health needs of AS, their change and the inequalities in access and to improve collaboration between groups and university.

Self-help as a relief strategy for Turkish family caregiver of people with dementia? A Scoping Review

Ilknur Özer Erdogdu

H Tezcan-Güntekin[1], I Özer-Erdogdu[1], Y Yilmaz-Aslan[2]
[1]Alice Salomon University of Applied Science, Berlin, Germany
[2]School of Public Health, Bielefeld University, Bielefeld, Germany
Contact: oezer@ash-berlin.eu

Background:

The number of dementia patients with a migration background is rising in the process of demographic change in Germany. For people with a migration background, care is usually provided at home and is accompanied by an increased burden on relatives. Alleviating support services are rarely used.

Methods:

The scoping review on burden and self-help as a relief strategy for Turkish family caregiver of people with dementia includes the databases PubMed, Livivo, CINAHL and Web of Science and is completed by a 'by hand' analysis in Google and Google Scholar. A total of 24 publications were included in the analysis.

Results:

Family caregiver of Turkish origin show a high degree of willingness to assume responsibility for care, show knowledge deficits with regard to support services and are exposed to heterogeneous burdens. People with a migration background hardly make use of self-help. Self-help as a relief strategy could be strengthened by needs-oriented and culturally diverse services.

Conclusions:

There is a need for action to improve domestic care for people with a migrant background. This requires the involvement of stakeholders such as those in need of care, caring relatives and professional carers. Self-help for people with a migration background can be activated and promoted with target group-oriented approaches. The support measures should be designed to be sensitive to diversity and correspond to the heterogeneity of the users and their life situations.

Key messages:

- Self-help for migrants must be flexible and user-oriented.
- Diversity-sensitivity in self-help could address people who are difficult to reach.

DC Digital health

Digital marketing in healthcare

Miljenko Grbic

M Grbic[1], D Stimac Grbic[2], L Stimac[3], Z Sostar[1]
[1]Andrija Stampar Teaching Institute of Public Health, Zagreb, Croatia
[2]University of Zagreb, School of Medicine, Zagreb, Croatia
[3]Faculty of Medicine, Novi Sad, Serbia
Contact: miljenko.grbic@gmail.com

We live in a digital world when people rely more on smart devices and dedicate their time to searching information online. According to some research, 85% of users now compare and check reviews of products or services prior to their selection, and Google states that as many as 77% of patients search the Internet before they are make decision. That is why more and more health organizations recognize the need for online presence and the use of digital channels to attract new clients. The age group of 15-35 which trusts social media and easier forms of communication when it comes to important decisions. This gives healthcare professionals a platform to engage with such an interactive audience easily.

Benefits - Health organization can either easily promote a product or service to the target group, as it is possible to determine who you want to target for preventive campaigns and services. In the digital world, you can easily measure and optimize results and gain accurate data as much as the range of activities.

Reach, Engagement, CPC? Reach shows how many users have seen the posting, and what is higher, it is spreading more widely. Engagement is the interaction you achieve with your target group. How can you determine that you have paid off and that you have achieved your goal? One of the real indicators of many parameters is certainly the CPC (Cost per Click). In digital marketing, CPC is an advertising payment model according to which an advertiser pays each time a user clicks on a link.

Conclusions:

The Healthcare industry remains behind other industries in the scope of digital marketing efforts. In 2017, only 50% of the survey respondents reported using a CRM system, while significantly more (65%) report using a CRM in 2018. Use of a marketing tool has doubled from last year’s survey, from 23% to 48%. Advanced or emerging digital activities, such as wearables or beacon technology, are still not being used much by healthcare organizations.

Key messages:

- Social networks empowers health clients.
- Majority people between the age group 18-24 (90%) trust information shared on social media.

Patient information ownership in the age of digital health and big data

Martin Mirchev

M Mirchev[1]
[1]Faculty of Public health, MU Varna, Varna, Bulgaria
Contact: mart_mirchev@abv.bg

Background:

In the context of digital health and the increasing capabilities to derive, store and use information, Big data, and data analytics provide an exceptional perspective towards the evolution of medicine and public health. We collect patient data at unimaginable scale thanks to technological improvements such as wearables, sensors, smart and mobile devices. We are digitizing health on our way to improve cares. The other side of the coin reveals specific issues: it is all about personal information. The risks we face in regard to privacy, autonomy and ultimately justice are worth debating.

Aim:

To consider whether ownership of patient data in the context of digital health and Big data is a good way to guarantee both privacy and the social interest in the field of public health.

Methods:

Historical, documental, ethical research.

Results:

The abilities to collect and store zettabytes of health-related information is spectacular, but learning how to structure and optimize the use of this information is pivotal for the future of public health. People are sensitive in terms of ‘‘ownership’’, rights and privacy, although the idea for actual ownership of health information is not quite popular. Given the fact, that it is personal data, a lot of concerns are related to ensuring privacy. One way to do it is by recognizing patient ownership over their data. The major issue with this, is that it might limit, or even prevent public interest, and so the public benefits. Having in mind the huge commercial interest in health data, that concern looks relevant. When applied in healthcare Big data has the potential to provide important data analytics, which means that we can move to next step in healthcare development - improving disease prevention and health promotion, which are vastly ignored in favor of clinical care. In this specific environment, it is highly questionable whether patient̓s ownership would bring more benefit, than harms in the shared goal of improving healthcare.

Key messages:

- What people might do if their health data is their property, might reflect in a bad way the common goal to structure and use it for health improving.
- Patient data ownership might not be reasonable in the long run, even though from an ethical standpoint and with regard to patient̓s autonomy looks fair.

Infographic as a form of communication in public health

Lovela Machala Poplašen

L Machala Poplašen[1], *Ž Draušnik*[2], *D Vočanec*[1], *H Brborović*[1]
[1]Andrija Štampar School of Public Health, University of Zagreb School of Medicine, Zagreb, Croatia
[2]Division for Public Health, Croatian Institute of Public Health, Zagreb, Croatia
Contact: lmachala@snz.hr

Background:

Infographics are a communication tool used in the digital environment that can present information, data or knowledge in an easy and understandable way to a wider audience. The aim of this study was to analyze if, and in which areas of public health, infographics are used as a form of communication in Croatia in relation to the world.

Methods:

The research analyses available infographics of leading institutions in public health in relation to Croatia and the world.

Results:

Visualization of key information is an accustomed concept in public health with infographics being a recognizable form of communication and an important part of digital health. However, only a small number of infographics in public health in Croatia are used. Infographics published in Croatia were mainly about exercise, cancer, ageing and stress. In the European Union, the topics found were aging, risk assessment, harassment/violence in the workplace and work-related stress. Infographics from the world addressed child labour, youth employment, gender equality, better work, dialogue promotion, migrant workforce, migration, domestic workers and safety at work. Moreover, International Labour Organisation made interactive media containing infographics - infostories - with topics: young workers, gender gap, migrants, non-standard employment, disability inclusion, forced labour and collective bargaining.

Conclusions:

We suggest to include more public health topics and to raise awareness among Croatian public health experts on the importance of infographics as a form of communication.

Key messages:

- Visualization of key statistical data in the style of infographics enables public health professionals to educate their employees and the public.
- Infographics are excellent tools for communicating important topics and are more likely to drive action and change behavior.

The meaningfulness of open data in Public Health and Healthcare

Joao Pita Costa

J Pita Costa[1], *F Fuart*[1], *B Cleland*[2], *J Wallace*[2], *A Staines*[3], *O Belar*[5], *J Bidaurrazaga*[5], *J Pääkkönen*[4], *G Epelde*[6], *P Poliwoda*[7]
[1]Quintelligence, Ljubljana, Slovenia
[2]Ulster University, Belfast, UK
[3]Dublin City University, Ireland, Ireland
[4]Oulu University, Oulu, Finland
[5]BIOEF, Bilbao, Spain
[6]Vicomtech, San Sebastian, Spain

[7]IBM, Dublin, Ireland
Contact: joao.pitacosta@ijs.si

Background:

The growing challenges and opportunities of Big Data for Public Health have revealed the potential to improve the efficiency and cost-effectiveness of public policy, for example through better targeting of resources with regard to General Practice (GP) prescribing. Open data has an important role due to its easy access and potential to complement proprietary data sources from, e.g., regional hospitals, and also itself be complemented with social data acquired by specialized approaches.

Methods:

MIDAS pipeline of open source tools aiming integrating, analysing and visualising Open Data enabling health professionals and decision-makers to: (i) improve the usability of open data in combination with proprietary data through combining multiple visualisation tools in an integrated dashboard (ii) to explore the meaning of data in a global/local context based on new information using tone analysis and natural language techniques; and (iii) to have better informed decision-making based on evidence from trusted knowledge-bases. Specific data sources used have included information extracted from the biomedical database MEDLINE, worldwide news and government open data. Social media sources have also been used to gather information from the general public.

Results:

Results include a strong correlation between antidepressant prescribing and economic deprivation, and a wide variation in how individual GP practices respond to demographic conditions. Automated anomaly detection based on the Local Outlier Probability has also been shown to be an easily understood and controllable approach to identifying prescribing outliers.

Conclusions:

MIDAS demonstrates the significant value of open data from heterogeneous sources as basis decision-making in public health and healthcare, particularly when it is combined with proprietary or closed datasets. A key challenge in this regard is the ability to integrate and utilize data from diverse sources in a variety of formats and standards.

Key messages:

- MIDAS is exemplar on tackling the need for improved standards of open data, and new software architectures, tools and platforms addressing a complex ecosystem of heterogenous data sources and formats.
- MIDAS demonstrates the significant value of open data from heterogeneous sources as basis decision-making in public health and healthcare, particularly when combined with proprietary datasets.

Use of social media in public and private hospitals in Italy: preliminary results

Umberto Gelatti

U Gelatti[1], *A De Bernardis*[2], *L Covolo*[1]
[1]Section of Public Health and Human Sciences, University of Brescia, Brescia, Italy
[2]School of Medicine, University of Brescia, Brescia, Italy
Contact: umberto.gelatti@unibs.it

Background:

In 2010, the Italian Ministry of Health set out recommendations for the use of Web 2.0, inviting organizations within the Italian National Health Service (INHS) to implement these tools. In 2014, a study carried out by the National Institute of Health showed a low presence of Local Health Authorities and Italian public hospitals on social media. Considering the constant increase of the use of social media in the population, the aim of the study is to understand if and how healthcare context is moving towards this direction.

Methods:

The list of all public and private hospitals in Italy were retrieved by the official website of INHS. The websites of all the hospitals (n = 1054) will be visited to look for the presence of social media. Engagement level and use of social media will be evaluated.

Results:

A preliminary analysis focused one 97 hospitals, of which 64 public and 33 private. Social media are present in 38 (39%) of them, particularly Facebook, Twitter and You Tube (92%). Only Twitter or YouTube are present in three hospitals. Social media are present more in hospitals in the North of Italy (58%) compared to Center (29%) and South (13%) ($p = 0.002$). Furthermore social media are present more in private hospitals than public (55% vs 44%, $p < 0.001$).

Conclusions:

Preliminary results show a low presence of hospitals on social media, with some differences between geographical areas and type of hospitals. Adherence to Ministry of Health's recommendations seems still low.

Key messages:

- Public health communication need to implement new strategies to increase public participation and provide reliable information using the information channels most used by the population.
- Considering the spread of health information through social media, an active presence of healthcare organizations on these channels could be an opportunity to engage people in health interventions.

Connecting Older Adults and Their Families through Social Technology

Janina Mueller

J Mueller[1], *H Foran*[1]
[1]Department of Health Psychology, Alpen-Adria-Universität Klagenfurt, Institute for Psychology, Klagenfurt, Austria
Contact: janina.mueller@aau.at

Background:

Older adults often face problems with social isolation, which is a risk factor for poorer mental and physical health. New forms of social technologies (e.g., WhatsApp) provide opportunities to facilitate social connectedness with family members. Understanding older adults' behaviors and perceptions related to digital communication tools can inform the development of interventions to increase the adoption of these tools for social communication. This study aims to evaluate attitudes and barriers to as well as facilitators of social technology reported by grandparents and grandchildren. The secondary aim is to examine the associations between social technology use and health and well-being outcomes and to identify what factors mediate the use of social technology.

Methods:

In this cross-sectional study, 144 grandchildren (Mage = 26.53, SD = 9.17; 81.9% female) were recruited through student mailing lists. Grandparents were invited either through their grandchild or by the research team and recruitment is expected to be completed by September 2019. Three main groups of variables were examined: health and well-being outcomes, social support related outcomes and social technology related outcomes.

Results & Conclusions:

Grandchildren reported very positive attitudes toward social technology as expected. Greater social technology use was associated with better psychological ($r = .26$, $p = .002$) and subjective well-being ($r_s = .20$, $p = .023$), higher psychosocial flourishing ($r = .41$, $p < .001$), social support ($r_s = .22$, $p = .009$) and social connectedness ($r = .39$, $p < .001$). Social technology use was not correlated with health, the grandparent-grandchild relationship, loneliness and depression at the bivariate level. Barriers to social technology are security concerns, threat to privacy and constant availability. Facilitators include increased contact, dealing with geographic boundaries and information seeking. Results from grandparents will also be presented.

Key messages:

- Social technology has potential to enhance older adults' lives by facilitating better family relationships, building social support, reducing loneliness and through this improve health and well-being.
- More research is needed in this area to understand benefits or potential harms and dynamics between younger family members and older adults in use of social technology.

StopBlues: a French e-health device to prevent suicide in the general population

Anaïs Le Jeannic

A Le Jeannic[1,2], C Gandré[2], MA Vinet[1,2], K Turmaine[2], JL Roelandt[2,3], B Giraudeau[4], C Alberti[2,5], K Chevreul[1,2]

[1]URC Eco, Assistance Publique-Hôpitaux de Paris, Inserm, Paris, France
[2]UMR1123, Inserm, Paris, France
[3]Centre Collaborateur de l'Organisation Mondiale de la Santé, Etablissement Public de Santé Mentale Lille-Métropole, Lille, France
[4]UMR 1246, Inserm, Tours, France
[5]UEC CIC 1426, Assistance Publique-Hôpitaux de Paris, Inserm, Paris, France
Contact: anais.lejeannic@urc-eco.fr

Background:

France is one of the Western European countries most affected by suicide, an epidemiological burden and high societal cost of several million euros/year. Several European projects have either implemented web-based interventions for care of mental disorders or recommended online actions which have demonstrated their effectiveness for suicide prevention.

The objective of the project was the construction of an application and website to prevent suicide in the general population, with its promotion being supported at the local authority level.

Methods:

The detailed content of the devices and promotional tools available to local authorities was determined through literature reviews and expert groups (psychiatrists, local authorities' workers and potential users).

Results:

An application and website were constructed with two parts: a public interface with videos (psychological suffering, coping strategies and help available), an emergency button, a map with local resources and contact information (psychiatrists, psychologists, associations...), tips and videos to overcome a period of psychological suffering; and a private interface requiring registration giving access to self-assessment questionnaires and a safety plan to fill in case of crisis. 40 local authorities are involved in StopBlues promotion, with a referent each, responsible of contact with our team, and local organization of promotion.

Conclusions:

Since 04-2018, StopBlues is available at www.stopblues.fr and can be downloaded on iOs and Android. Its promotion is part of a cluster randomized trial with 3 arms: a control group with no promotion, a group with promotion by local authorities, and a group with promotion by local authorities and general practitioner's waiting room. As promotion could have different intensities depending on budgets and referent's involvement, we decided to extend it for another year, with local authorities of group control receiving additional financial and organizational support.

Key messages:

- As the first e-health program for suicide primary prevention in the French general population, StopBlues' main goal is to help people find solutions that suit them and direct them to the right help.
- Local authorities are a key level to promote primary health prevention programs.

Role of Social Media in vaccination debate about HPV: the VAC Medi+Board study

Daniel Artus

D Artus[1], H Larson[2], P Kostkova[3]

[1]UCL Department of Geography, University College London, London, UK
[2]Department of Infectious Disease Epidemiology, LSHTM, London, UK
[3]UCL IRDR Centre for Digital Public Health in Emergencies, University College London, London, UK
Contact: dan.artus@ucl.ac.uk

Background:

Whilst it has long been known that anti-vaccination sentiment is widely disseminated through digital networks, 2019 has seen seismic shifts in the landscape. As viral videos originating on Youtube spread across social networks, HPV vaccine uptake tumbled in a number of countries. In Japan, the government came under sufficient pressure that they de-recommended HPV vaccine, seeing a 70% uptake rate in 2013 fall below 1%. However, there have been some reports of successful interventions - a recent campaign run by the HPV Alliance in Ireland has seen a rate back up to a national average of around 75%. A combination of hard-hitting personal testimonials, social media and traditional media looked to promote the HPV vaccine.

Methods:

Social media platforms such as Twitter enable near real-time understandings of vaccine sentiment and information flows at scale. VAC Medi+Board project developed an innovative approach for Twitter data collection, integration, analysis and visualisation to support rapid responses through identifying key influencers and flashpoints in articles about vaccination going viral.

Results:

This pilot study evaluated the debate about HPV on Twitter in a period of several month and developed methods for analysis and visualisation of the content, key influencers, information diffusion throughout the network and size of audience. Through complex network analysis, VAC Medi+Board piloted identification of individuals for targeted public health interventions to combat misinformation.

Conclusions:

In this talk, we will present the VAC Medi+Board HPV study and explore the challenges and opportunities that social media can provide for public health policymakers.

Key messages:

- Analysis and graphical visualisation of HPV debate on Twitter to support targeted public health interventions at real-time.
- Contributing to better understanding the role of social media in the complex picture of vaccines hesitancy.

ZIKA: improved surveillance and forecast of Zika virus in Brazil

Patty Kostkova

P Kostkova[1], W Pinheiro dos Santos[2], T Massoni[3]

[1]UCL IRDR Centre for Digital Public Health in Emergencies, UCL, London, UK
[2]Department of Biomedical Engineering, Federal University of Pernambuco, Recife, Brazil
[3]Department of Systems and Computing, Federal University of Campina Grande, Campina Grande, Brazil
Contact: p.kostkova@ucl.ac.uk

Background:

The devastating consequences in neonates infected with Zika virus make controlling the spread of the virus and its vectors (Aedes mosquitoes) an urgent challenge. Mobile technology has been successfully used to support routine surveillance of mosquito populations conducted by the community health workers (health agents). Mobile real-time surveillance data also provides a ground truth for calibrating early-warning and prediction systems.

Methods:

The ZIKA app supports the health agents in routine surveillance of properties with risk of mosquito breeding, recommends the most optimal route to visit the assigned properties, and includes gamification features, such as badges, to reward healthcare agents for successfully completing the surveillance tasks. Secondly, the project developed a model of the vector population spread using neural networks and artificial intelligence methods combing data from healthcare agents and mosquito ovitraps from the period 2009-2014, with climatic and weather data, calibrated by the real time data from the ZIKA app.

Results:

The results from testing sessions demonstrated the app could replace the very time consuming paper-based systems and provide an improved surveillance data available at real time, for seamless reporting to the regional authorities. Using the 2009-2014 dataset, the neural network model successfully predicts mosquito occurrence in the high risk regions of the city of Recife.

Conclusions:

The ZIKA mobile app provides a much improved surveillance of the mosquito populations and real-time data for the public health authorities responsible for rapid response. The AI early warning model successfully predicts mosquito populations using healthcare agents data, weather and climatic data.

Key messages:

- ZIKA project developed a mobile app to improve surveillance of mosquito population in tropical regions of Brazil.
- ZIKA early warning system, using AI neural networks, has the potential to predict the risk of mosquito populations in high risk urban locations.

The use of E-sexual health as a way of lowering help-seeking barriers for sexual dysfunctions

Claudia Van Der Heijde

CM Van Der Heijde[1], I Bunte[1,2], F Hilverda[2], P Vonk[1]
[1]Student Health Service, University of Amsterdam, Amsterdam, Netherlands
[2]Athena Institute for Research on Innovation and Communicati, Vrije Universiteit Amsterdam, Amsterdam, Netherlands
Contact: c.m.vanderheijde@uva.nl

Background:

The prevalence of sexual dysfunctions is not negligible and experiencing a sexual problem is often accompanied by psychosocial effects, increasing the risk of comorbidities such as depression, greater levels of anxiety and lower self-esteem. Less than half of the individuals who experience sexual problems seek professional help, partially because of stigma and ignorance. Therefore a solution is required. E-sexual health has potential to help individuals with sexual dysfunctions, but little is known about its' use.

Methods:

We examined the predictors of E-sexual health usage using the Technology Acceptance Model (TAM). Perceived usefulness, ease of use, attitude, and intention to use E-sexual health were explored as potential predictors in a cross-sectional survey (N = 426). 413 of them were female, 180 male, aged from 18 to 72 years (M = 24.5, sd = 7.8). Structural equation modeling (SEM) was used to test the model.

Results:

The results showed that TAM can effectively predict whether patients adopt E-sexual health. The model demonstrated a good fit ($\chi 2$ = 1197.73, df = 500, $\chi 2$/df = 2.40 TLI = .913, CFI = .927, IFI = .927, RMSEA = .048). Notwithstanding, it appeared that the current use and implementation of E-sexual health is much lower compared to several other E-health services.

Conclusions:

It should be taken into account by healthcare providers that people are hesitant to disclose sexual problems. Further research is necessary to find out how to increase awareness of the relevance of treating sexual problems and how to increase knowledge about the possibilities of E-sexual health and its' usefulness.

Key messages:

- E-sexual health has the potential to reach more patients with sexual dysfunctions.
- Increasing awareness for the relevance of treating sexual dysfunctions, and the potential of E-sexual health can lower the barriers for help-seeking behavior.

Healthcare digital services in Italy: good practices across Regions

Elisa Guidotti

SZ Zuccarino[1], EG Guidotti[1], MC Cassano[1], SDR De Rosis[1], FF Ferrè[1]
[1]Institute of Management and Department EMbeDS, Scuola Superiore Sant'Anna, Pisa, Italy
Contact: guidottiel@gmail.com

Background:

In Europe, digital transformation of healthcare is one of the agenda priorities. Institutional websites and mobile applications (APPs) have been increasingly adopted by healthcare organizations for communication and service delivery. This study aims at describing the state of art and the variability of healthcare digitalization in Italy.

Methods:

The study focuses on 144 active websites of public healthcare organizations (i.e. Local Health Authorities and Teaching Hospitals) of 11 out of the 21 Regional healthcare systems in Italy. The research investigates whether the healthcare organizations provide e-booking and e-paying for outpatient visits through their website/APP and whether citizens are informed of this opportunity. Researchers independently analyze the websites taking the user's perspective, by adopting a common grid. Data refers to December 2018.

Results:

The majority of items analyzed show a high variability within and among Regions. The provision of online services patients can benefit of change across the same territory. Almost 76% of the LHAs/hospitals allow for e-booking of outpatient visits and e-paying is available for 84% of them. The adoption of APPs for healthcare is not homogenous. Some Regions develop a specific regional tool (e.g. Apulia, Lombardy) providing uniform access to digital services to their resident population while in other Regions, public healthcare providers can implement their own APP (e.g. Liguria, Veneto).

Conclusions:

Our findings suggest that centralizing digital services - at least at regional level - can enhance healthcare digitalization in Italy, avoiding jeopardized and unequal provision of digital services. Further research should investigate the actual use of these services by citizens and the reasons of variability.

Key messages:

- Italy is in delay in digital transformation of healthcare.
- Our study supports the identification of good regional practices, which could endorse the implementation of future actions.

Understanding non-compliance with surgical antibiotic prophylaxis prescribing guidance, in Nigeria

Caroline Wood

C Wood[1], P Kostkova[1], O Olufemi[2], D Soriano[1], F Ogunsola[2], C Lefevre-Lewis[3], E Kpokiri[4], L Shallcross[5]
[1]UCL IRDR Centre for Digital Public Health in Emergencies, University College London, London, UK
[2]Lagos University College of Medicine, Lagos University, Lagos, Nigeria
[3]UCL Centre for Behaviour Change, University College London, London, UK
[4]Antimicrobial Resistance Centre, LSHTM, London, UK
[5]Institute of Health Informatics, University College London, London, UK
Contact: caroline.wood@ucl.ac.uk

Background:

Antimicrobial Resistance is a prominent worldwide threat that is increasing in low-to-middle income countries. Good antibiotic stewardship (AMS) improves compliance with evidence-based antimicrobial prescribing guidelines but just 4% of LMICs have national AMS initiatives in place and only 15% have national policies. As high as 20-50% of surgical antibiotic prophylaxis prescription in Nigeria is thought to be non-compliant. Behaviour change theories can structure our understanding of why poor compliance occurs and can facilitate development of effective interventions to improve it.

Methods:

The Theoretical Domains Framework (TDF; Michie et al. 2009) was used to develop an online survey and interview schedule for focus group discussions. Audio recordings were transcribed and analysed by two researchers using thematic analysis, TDF and the COM-B model of behaviour change (Michie et al. 2010).

Results:

60 surgeons (59% male; 43% surgical consultant; 5-10 yrs experience) from Lagos University Teaching Hospital, Lagos University College of Medicine and Niger Delta University Teaching Hospital completed the survey. A sub-group of 14 surgeons (79% male; 86% surgical consultant; 10-15 yrs experience) participated in three focus groups. Whilst compliance with guidance was generally considered desirable, surgeons reported translating guidance to Nigerian practice and context was often difficult, time-consuming and restricted by not having access to recommended antibiotics.

Conclusions:

Behaviour change theory can be used to further our understanding of key barriers and facilitators to non-compliance with surgical antibiotic prophylaxis prescribing guidance, amongst surgeons in Nigeria. This presentation will conclude with discussion of how findings from this project are being used to develop a cost-effective, scalable, decision-support smartphone app for prescribing behaviour change.

Key messages:

- Behaviour change theory can be used effectively to further understanding of barriers and facilitators to Nigerian surgeons' non-compliance with surgical antibiotic prophylaxis prescribing guidance.
- We must form a comprehensive understanding of factors (social & environmental) driving non-compliant attitudes and behaviours, before creating interventions to change prescribing behaviour.

eHealth Literacy and Fertility – managing complex information in a digital environment

Susie Sykes

S Sykes[1], *J Wills*[1]
[1]London South Bank University, London, UK
Contact: sykess@lsbu.ac.uk

Background:

There is increasing reliance on the internet as a source of health information including for those seeking information about fertility. This study investigates how people access, understand and process online fertility information and engage with digital services.

Methods:

Purposive sampling was used to recruit 27 participants from a range of groups including those diagnosed with infertility, those who successfully conceived after a period of infertility, same sex couples, those over 40 and younger people making decisions about delaying parenthood. Semi structured telephone interviews explored information seeking behaviour and ehealth literacy competencies. Data were analysed using thematic analysis.

Results:

Digital platforms were identified as a primary source of information but presented barriers including gaps in content, and concerns about relevancy and complexity. Source credibility was a priority alongside a recognition that emotional drivers led to the active seeking of specific information. Participants described a journey from general information to specific, detailed and tailored content. Participants moved between conversational forums on social media sites and information based internet platforms as part of an ongoing process of identifying and understanding information. However, participants were typically purveyors of information in their real world relationships. Information was used to prepare for and understand interactions with health professionals.

Conclusions:

Sources of digital information need to respond to the ehealth literacy competencies of users. Users go beyond the passive accessing of information through digital platforms and are actively engaged as contributors of information through social media and app based technology. The value placed on other people in accessing and understanding fertility information, through online forums and virtual communities, shows the importance and complexity of distributed health literacy.

Key messages:

- Digital platforms are a key source of information around fertility.
- Interaction with digital platforms is complex and requires the digital environment to respond to their ehealth literacy needs.

Artificial Intelligence-based tools to control healthcare associated infections: where do we stand

Anna Odone

A Scardoni[1], *F Balzarini*[1], *F Cabitza*[2,3], *A Odone*[1]
[1]Scuola di Specializzazione in Igiene e Medicina Preventiva, University Vita-Salute San Raffaele, Milan, Italy
[2]Department of Informatics, University of Milano-Bicocca, Milan, Italy
[3]IRCCS Istituto Ortopedico Galeazzi, Milan, Italy
Contact: anna.odone@mail.harvard.edu

Background:

Control of Healthcare associated infections (HAI) is a key public health concern in Europe. Current HAI surveillance systems are based on manual medical records review, vulnerable to misclassification and expensive. Artificial intelligence (AI) offers great potential to public health action and, specifically, to HAI control. Still, scant evidence is available on both its practice and impact.

Methods:

As part of a broader multidisciplinary project, we conducted a systematic review to retrieve, pool and critically apprize all the available evidence on practice, performance and impact of AI-based HAI control programmes. We followed PRISMA guidelines and searched the Medline and Embase databases for relevant studies. Included studies were stratified by HAI type and outcomes of interest, including all possible performance measures, clinical, organizational and economic outcomes.

Results:

We screened 2873 records, resulting in 27 papers included in the review. Studies were carried out in 9 countries, the majority in the US (56%), 18.5% in EU countries, 25.9% published in 2018. Two thirds of studies focused on selected types of infections. Study designs were very diverse and performance observed for HAI detection were very heterogeneous, precluding pooled calculation of summary diagnostic accuracy estimates in most instances, but generally higher than non AI-based models. The highest performance outcomes were Specificity and Negative Predictive Value. Overall performance measures of AI algorithms were: sensitivity range 19%-92%, specificity range 64%-96%, accuracy 70.2%-96.1%.

Conclusions:

Use of AI algorithms for HAI surveillance of HAI has increased reliability compared to traditional surveillance or to automated surveillance models. With ongoing improvements in information technology, implementation of AI models will improve the quality and capacity of surveillance will support hospital HAI surveillance.

Key messages:

- Artificial Intelligence (AI) offer great potential to healthcare associated infections (HAI) control.
- Preliminary evidence show AI-based models have perform better than manual or automated models for HAIs detection.

Addressing equity in eHealth interventions for healthcare system users & patients, literature review

Viviane Ramel

V Ramel[1]
[1]Bordeaux Population Health Center, Inserm U1219, EMOS Team, Bordeaux University, Bordeaux, France
Contact: viviane.ramel@u-bordeaux.fr

Objective:

eHealth has great potential to improve access to health information and care but important barriers to equity still exist and a real digital divide threatens its use. It is therefore necessary to build a conceptual framework on digital health interventions aiming at promoting equity and to analyse the strategies and recommendations that arise through the literature. Such a conceptual framework has not been identified in the literature yet.

Methods:

We carried out a scoping literature review of the scientific literature since 2000 in Western countries, in Scopus, PubMed, PsycArticles, SocIndex and PBSC.

Results:

Strategies that take into account equity in eHealth for healthcare system users and patients can be presented in light of the five key action areas of the Ottawa Charter for Health Promotion. They deal with the policy level, the individual one, aim at creating supportive environments, at using the community level for eHealth promotion and focus on health services. Individuals-oriented interventions are the most reported, thus revealing a lack of systematic thinking and certainly a lack of understanding of the whole spectrum of health determinants.

Conclusions:

Following Gibbons' expression of "compunetics" (Information and Communication Technologies & ethics), interventions that truly consider the unintended consequences of eHealth on social and geographic health inequalities are absolutely necessary. The conceptual model analysing the whole literature on this interaction makes it easy to understand the types of interventions that are or could be carried out to tackle equity issues in digital health interventions. Its recommendations become easy to implement in the field and can be extremely helpful for decision-making.

Key messages:

- Strategies that take into account equity in eHealth for healthcare system users and patients can be presented in light of the five key action areas of the Ottawa Charter for Health Promotion.
- The conceptual model we elaborated makes it easy to understand the types of interventions that could be carried out to tackle equity issues in digital health interventions.

Identifying latent needs in elderly digital literacy: the PROADAS study

Giagkos Lavranos

M Prodromou[1], *G Lavranos*[1]
[1]European University Cyprus, Engkomi, Cyprus
Contact: G.Lavranos@external.euc.ac.cy

Background:

According to the Digital Agenda for Europe (2014 - 2020) enhancing digital literacy, skills and inclusion is one of the main priorities. All European elderly people must become e-seniors as soon as possible. On the hand, active ageing means that senior citizens activate themselves in order to be as independent as possible. As a result, triggering these new digital tools and ICT skills can assist the elderly to be a more integrated part of our society. The Erasmus+ Proadas project promotion of Active Digital Ageing Skills aims at tackling the gap between ageing population and digital literacy and strengthening and reinforcing the stakeholders, experts and practitioners, by identifying the needs of elderly people and their carers regarding technology.

Methods:

The study was conducted in January 2019 in all six countries participating in the Proadas project. 35 carers and their assigned seniors were selected via convenience sampling by a minimum of three best practices- centres of excellence per country. A twelve-question close format questionnaire was developed, using a Delphi approach and completed by all participants. All data was analysed using SPPS 20.

Results:

A total of 188 responders from all six countries agreed to participate response rate 89.5% of which 51.5% women. Age varied significantly between 20-75 years. Regarding existing ICT skills participants in all countries were familiar with basic use of computer and internet but very few used advance services. There was unanimous agreement that learning is facilitatedwith the help of family or friends. A combination of traditional and digital learning format was deemed most appropriate. The main obstacles involved lack of trainers, motivation and suitable educators.

Conclusions:

There is latent need for the integration of ICT in elderly care. The development of suitable learning material and the involvement of motivated carers are key strategies for the successful implementation of such a reform.

Key messages:

- ICT is insufficiently used for elderly health education.
- Digital health can be beneficial for the elderly and their carers.

Social capital and social networks

Elisabetta Corvo

E Corvo[1], *W De Caro*[2]
[1]School of Allied and Public Health Professions, Canterbury Christ Church, Canterbury, UK
[2]CNAI Italian Nurses Association, Milan, Italy
Contact: elisabetta.corvo@canterbury.ac.uk

Introduction:

Social capital can be defined as the 'sum of the resources, actual or virtual, that accrue to an individual or a group by virtue of possessing a durable network of networks or less institutionalized relationships of mutual acquaintance and recognition'. Nowadays there are a number of new way to have social relationship. Developing community and individual social capital is an important aspect for health promotion in order to decrease social isolation and health inequalities.

Methods:

This research aims to detect to what extend online social networks can help in building social capital and decrease social isolation. An analysis of the content of an open Facebook group of people who are experiencing chronic diseases was carried out (7912 individuals).

Results:

Text mining analysis was carried out, as well as a content analysis in order to identify which kind of social support and social capital emerged among participants. Results based on text mining (234.943 words) and thematic analysis (information, relationship, support) show that even virtual social group have an important impact on participants' wellbeing and health. Participants seems to develop through participation all construct of social capital i.e. bonding, bridging and linking social capital. There is an overall increase in confidence and sense of community. However, virtual communication seems lacking of a number of crucial aspect of human interaction such as face to face communication or physical contact.

Conclusions:

The use of social network as a new place of aggregation and socialization is an important aspect to look at. Virtual networks can have a role in developing relationship and to build trustiness on individuals. Public Health and Health Promotion, as well as health care professionals should be aware and concern about social capital as a key aspect of health and explore in depth the role of new social networks as a new way to build social capital and health of individuals and communities.

Key messages:

- Text mining as new useful tools for health research.
- Social capital and social network intersection.

DD European and global health

Promoting healthy sustainable societies through a circular analytical dialogue method

Stéphanie Paillard-Borg

S Paillard-Borg[1]
[1]Department of Health Sciences, The Swedish Red Cross University College, Huddinge, Sweden
Contact: pais@rkh.se

Background:

The relationship between journalists and populations is complicated and the subject of ''fake news'' is one of these related issues. Despite the controversy, journalistic media are the ground to a well-informed society and as such journalists have the potential to be important actors in the pursuit of population health. At the same time, frustration against journalistic media has increased globally and vulnerable and so-called 'invisible' groups feel neglected by the media.

Methods:

The Circular Analytical Dialogue is an innovative method for examining the dialogue between journalists and citizens and investigating the role of journalism in promoting social cohesion, population health and democracy.

Results:

The preliminary results of a pilot study in Japan on the topic of migration, using the Circular Analytical Dialogue, show that the dynamic between the participants and the journalists was valued by all parties as it allowed a profound and valuable dialogue. The journalist was most appreciative of the feedback of the participants as it opened alternative perspectives that were not considered beforehand.

Conclusions:

The Circular Analytical Dialogue has the dual ambition to be a research as well as a journalistic tool and the knowledge generated with this method is intended to be used to strengthen understanding about the importance of journalism for healthy democratic societies.

Key messages:

- The Circular Analytical Dialogue method reinforces the importance of academic activism strongly related to sustainable societies.
- The Circular Analytical Dialogue method can potentially contribute to the empowerment of populations fundamental to population health.

Primary care providers' beliefs and practices on colorectal cancer screening in Kuwait

Eleni Tolma

EL Tolma[1], *SM Aljunid*[1], *MN Amrizal*[2], *J Longenecker*[1,3], *A Al-Basmy*[4], *M Annaka*[5], *R Al-Wotayan*[5]
[1]Facutly of Public Health, Kuwait University Health Sciences Center, Kuwait City, Kuwait
[2]Faculty of Medicine, National University of Malaysia, Kuala Lumpur, Malaysia
[3]Faculty of Medicine, Kuwait University, Kuwait City, Kuwait
[4]Kuwait Cancer Control Center, Ministry of Health, Kuwait City, Kuwait
[5]Primary Care Department, Ministry of Health, Kuwait City, Kuwait
Contact: eleni.tolma@hsc.edu.kw

Background:

Colorectal cancer (CRC) is a major public health issue in the Arab region. In Kuwait, CRC is the second most frequent cancer, with an age-standardized (world) incidence rate of 13.2 cases/100,000 in 2018. Despite the national efforts to promote CRC screening the current participation rate is very low (5 to 17%). Primary Care Providers (PCPs) are considered as the gatekeepers of cancer screening globally. This is one of the first studies in Kuwait that examined the current beliefs/practices of PCPs on CRC screening.

Methods:

This cross-sectional study was conducted at governmental primary care centers in Kuwait from 2015-2017. Of 564 PCPs invited to participate from all centers, 255 completed the self-administered questionnaires. The 14-page survey contained 75 questions on PCPs' beliefs and practices of CRC screening. Data were analyzed by using descriptive statistics.

Results:

The study sample consisted primarily of females (52.0%) and non-Kuwaiti (79%) physicians, with mean age =43.3 (SD: 11.2) years. Most respondents (92%) believed that colonoscopy is the most effective screening tool. The majority (78%) reported that they recommend CRC screening to their patients, with colonoscopy as the most frequent modality (87%) followed by the Faecal Occult Blood Test (FOBT) (52%). Around 40% of the respondents stated that they did not have time to discuss CRC screening with their patients. The majority (72%) believed that their patients did not complete their CRC screening tests. Health system related barriers included difficulties in obtaining test results from the gastroenterologist (61.4%), ordering follow-up test after a positive screening test (50.6%) and shortage of trained staff to conduct the screening test (44.2%).

Conclusions:

A majority of PCPs in Kuwait recommend CRC screening to their patients, but not all patients follow through their recommendation. More research is needed to find out how to further enhance patient uptake of CRC screening.

Key messages:

- Colonoscopy is the most frequent screening CRC modality used in Kuwait.
- Health system related factors can be important future intervention targets to promote CRC screening.

Women political empowerment and child health: an empirical analysis, 1990-2016

Elodie Besnier

E Besnier[1]
[1]CHAIN, Department of Sociology and Political Science, NTNU, Trondheim, Norway
Contact: elodie.besnier@ntnu.no

Empowering women has been presented as a key strategy to improve child health. Yet, the literature on the subject is mixed, with strong variations in measures or according to context. Additionally, most of the research focuses on social or economic empowerment at the individual level rather than on structural factors or political empowerment. In this study, we explore whether women political empowerment is associated with improved health for children under 5 years old, in comparison to socio-economic empowerment or structural factors from the sustainable development agenda.

We use the V-Dem project's Women's Political Empowerment Index and its components, combined with selected indicators of child health from the World Bank's World Development Indicators for 166 countries, between 1990 and 2016. We estimate random- and fixed-effects regressions for the index as a whole and its individual components against child mortality, stunting and immunization coverage, controlling for structural and socio-economic indicators.

The association between women political empowerment and child health outcomes tends to weaken once country heterogeneity is accounted for. Looking at individual components of women empowerment, factors or markers of socio-economic empowerment tend to have a stronger positive effect on child health compared to more political ones, for which we found either no correlations or even detrimental links to child health outcomes.

Our results demonstrate the complexity of the relations linking women empowerment and child health. Presenting women political empowerment as a whole as the solution to improved child health appears misguided. However, selected individual freedoms and markers of women socio-economic empowerment are associated with positive effects on specific child health outcomes. This calls for a more context-specific yet multi-dimensional approach to women empowerment and child health in order to provide cohesive evidence to achieve the related SDGs.

Key messages:

- The relations between different dimensions of women empowerment and child health are complex.
- Women socio-economic empowerment may offer better leverages than political empowerment to improve child health.

Is the French Emergency Medical Service System duplicable in developing countries?

Helene Rossinot

H Rossinot[1], *C Lapandry*[1], *F Adnet*[2], *P Carli*[3], *E Lecarpentier*[4], *M Baer*[5], *F Veber*[1]
[1]Délégation aux Relations Internationales, AP-HP, Paris, France
[2]SAMU AP-HP Avicenne, AP-HP, Bobigny, France
[3]SAMU AP-HP Necker, AP-HP, Paris, France
[4]SAMU AP-HP Henri Mondor, AP-HP, Créteil, France
[5]SAMU AP-HP Raymond poincaré, AP-HP, Garches, France
Contact: helene.rossinot@yahoo.fr

Issue:

The management of pre-hospital emergencies is a growing issue in developing countries, particularly because of the increase of both road accidents and cardio-vascular diseases.

Description of the problem:

Numerous countries have tried or are currently trying to develop emergency response systems like the French SAMU but the outcome of those actions show a lot of difficulties. It is however proved that efficient care of serious pre-hospital medical emergencies significantly improves both patients' mortality and morbidity.

Results:

AP-HP, Greater Paris University Hospitals, has a strong experience of supporting the development of this model of care in countries with limited resources. Most of last 30 years' experiments have been reviewed to understand what the essential prerequisites to succeed in setting up an emergency response system such as SAMU are. The analysis (5 criteria evaluation: efficiency, sustainability, effectiveness, impact, relevance) of past and present experiments in 28 countries showed that main issues are political (what are the priorities?), financial and societal (what does the population expect?). The question of medical resources is also crucial as the French model introduces medical regulation at all levels. Moreover, in France, such a system is built as a health care pathway with a predetermined orientation towards the appropriate and operational structure, which unfortunately is not the case in a lot of countries. Aside from those realized in China or in some Southern American countries, most of the projects so far don't match all the evaluation criteria, particularly sustainability, as it is based both on stable funding and a strong reactivity of local hospitals.

Lessons:

Future projects will have to fit with the local context. Strong commitments from partner countries must be made on the long term to have a real impact.

Key messages:

- There is no universal system easily duplicable.
- Some major prerequisites must be identified and implemented to succeed in the set-up of an efficient and sustainable EMSS.

How aligned are the WHO European Region policy documents to the Sustainable Development Goals?

Katya Andrea Nogales Crespo

KN Nogales[1,2,3], *AA Abrantes*[1]
[1]National School of Public Health, Nova University of Lisbon, Lisbon, Portugal
[2]Department of Culture and Communication, Linköping University, Linköping, Sweden
[3]Institute for Advanced Studies and Research, University of Évora, Évora, Portugal
Contact: kanc@uevora.pt

Background:

The 2030 Agenda for Sustainable Development presents an unprecedented opportunity to apply an ecological perspective in public health. It's success relays on the capacity to interpret and translate embodied principles into policies and actions. Regional policy document (PDs) guide the actions taken by the World Health Organization (WHO) and the Member States. This study aims to explore the alignment between these tools and the health-related Sustainable Development Goals (SDGs) in the WHO European Region.

Methods:

PDs were identified scanning the contents of the 2015-2018 Sessions of the Regional Committee for Europe - the WHO decision-making body. 17 PDs endorsed during this period were directly included. 39 Progress reports were scanned to find additional valid PDs. The Final list included 32 items. A content analysis of the PDs was used to establish alignment to 64 health-related SDGs targets.

Results:

Preliminary results found that each PD aligned to multiple targets within and beyond SDG 3. 24 PDs addressed all targets of SDG 3. A gap within target 3.b was identified (development of medicines and vaccines). Three PDs dealt with health issues outside SDG 3: target 2.1 and 2.2 (end hunger and malnutrition), 15.8 (prevent and reduce the impact of invasive species), and 16.2 (end violence and abuse against children). Five crosscutting PDs aimed to reduce the impact of social, economic and environmental determinants of health on specific population groups, aligning to several targets at the time. Gaps in Target 8.7 (eradicate forced labor) and 14.2 (protect marine and coastal ecosystems) were found.

Conclusions:

PDs have the potential of contributing to several targets simultaneously, linking health to diverse aspects of sustainable development. The SDGs open the possibility for multisectoral actions. PDs invite decision-makers to venture into unconventional policy fields to address public health concerns raised by climate change and sustainable development.

Key messages:

- Policy documents are a valuable instrument to advance the 2030 Agenda as they enjoy the commitment of Member States and guide the action taken by international and national decision makers.
- The ecological perspective in public health promised by the 2030 Agenda demands actions beyond SDG 3, to address the health dimension of all aspects of sustainable development.

Physical activity and self-perceived health of women in the Province of Vojvodina

Dragana Milijasevic

D Milijasevic[1,2], *V Mijatovic Jovanovic*[1,2], *S Susnjevic*[1,2], *S Ukropina*[1,2], *T Tomasevic*[1,2]
[1]Social Medicine, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia
[2]Center for Analysis, Planning and Organization of Health car, Institute of Public Health, Novi Sad, Serbia
Contact: dragana.milijasevic@izjzv.org.rs

Introduction:

Women suffer from many diseases that are associated with low level of physical activity. The aim of this paper was to estimate the association between physical activity and self- perceived health of women in the Province of Vojvodina.

Methods:

Research was conducted as a cross-sectional study on a sample of 1356 women aged 20-65 years in Vojvodina, as a part of the National Health Survey in Serbia, 2013. Physical activity was analysed through 3 domains of physical activity - as leisure time physical activity, walking and cycling for transportation and physical activity at work. Univariate and binary logistic regression was used to estimate the association of poor self-perceived health as dependent variable with 3 domains of physical activity. Multivariate model were adjusted for age, type of settlement, DHS Wealth Index, education and employment status.

Results:

One of twelve women was physically active in leisure time 150 minutes and more (8.1%), 50.0% of women walked for transportation 150 minutes and more weekly, while 16.5% cycled 150 minutes and more weekly. Women who never walked for transportation had 9.17 time higher chance to self-perceived their health as poor compared to those who are active 150 minutes and more weekly (OR = 9.17; 95%CI 4.16-20.18), while women who are inactive at work had 1.74 higher chance to self-perceived their health as poor compared to working active women (OR = 1.74; 95%CI 1.14-2.66).

Conclusions:

Physical activity at work and in the form of walking for transportation showed as predictors of poor self-perceived health.

Key messages:

- Regular physical activity can improve womens' health and help prevent many of the diseases and conditions that are major causes of death and disability for women around the world.
- Physical activity can contribute to building self-esteem and confidence and can provide a vehicle for social integration and equality for women in society.

High-throughput profiling of health-associated political, economic, commercial and social factors

José Luis Sandoval

JL Sandoval[1]*, D de Ridder*[1]*, S Stringhini*[1]*, I Guessous*[1]

[1]Unit of Population Epidemiology, Geneva University Hospitals, Unit of Population Epidemiology, Geneva, Switzerland

Contact: jose.sandoval@cantab.net

Background:

Political, economic, commercial and social factors have considerable impact in shaping health outcomes. Yet, most research is hypothesis-driven and, probably, not fully exploring the available data. We aimed at adapting gene expression profiling methods to perform unsupervised high-throughput profiling analysis of large databases of country indicators associated with life expectancy at birth.

Methods:

We analysed 464 World Bank development indicators for 217 countries using a Limma software R package. We established the differentially represented indicators (DRIs) between countries in the first and third terciles of life expectancy at birth. The analysis was stratified according to high (HIC), middle- (MIC) or low-income (LIC) status. Indicator profiles by development category were compared to determine overlaps and group-specific DRIs. Confounder-adjusted multivariable linear regression models were used to validate chosen DRIs.

Results:

We identified 99 DRIs for HICs, 7 for MICs and 190 for LICs. One DRI was common to all categories - ''particulate emission damage (% of GNI)'' (adjusted p.value = 7.3E-5). This DRI was negatively associated with life expectancy despite adjustment for GDP per capita (GDP), human capital index (HCI) and development classification (Beta = -2.7, $p < 0.001$). We also analysed the 7 identified gender-related DRIs. Only female murder rate (per 100 000 females) was negatively associated with life expectancy, independently of GDP, HCI, GINI index, education parity indexes, overall and male murder rates (Beta = -2.1, p = 0.001). This association was found in HICs (p = 0.001) and MICs (p = 0.03), but not in LICs (p = 0.4).

Conclusions:

Bioinformatics methods could help to analyse large country level datasets, allowing the profiling of DRIs and identify potential new determinants of health or health-associated indicators.

Key messages:

- Using bioinformatics tools can be useful in uncovering health-associated indicators for global health.
- Particulate emission damage or female murder rate could represent potential important determinants of health or health-associated indicators.

A practical guide to make the case for sustainable investment in well-being and health

Mariana Dyakova

A Stielke[1]*, K Ashton*[1]*, M Dyakova*[1]*, M Bellis*[1]

[1]WHO CC on Investment for Health and Well-being, Public Health Wales, Cardiff, UK

Contact: mariana.dyakova@wales.nhs.uk

Growing health, inequity, economic and environmental challenges threaten the well-being of present and future generations. Current investment policies and practices are unsustainable and result in high human, social, economic and environmental costs. Countries require the tools to build the case for investment in areas of greatest need by applying evidence-informed practice.

A practical guide with tools and resources was developed on how to develop an evidence-informed product to make the case for investment in well-being and health equity.

Stakeholder interviews with national and international experts in health policy, equity, economics and social sciences were conducted to inform the outline of the guide and identify enablers for creating evidence-informed products. An evidence review gathered tools and resources on how to translate and communicate public health evidence into policy and practice. An international cross-sector expert consultation assured relevance and transferability of the guide across countries, contexts and policies.

The guide aims to prevent disinvestment in health and increase investment in prevention as well as mainstream cross-sector investment to target the wider determinants of well-being and health equity. It outlines how to synthesise, translate and communicate public health and health economic evidence into policy and practice and proposes a step-by-step approach following four key phases (i) project scoping and planning, (ii) evidence gathering, synthesis and design, (iii) dissemination and communication, (iv) monitoring and evaluation.

The guide presents information to develop an evidence-informed product to make the case for sustainable investment in an innovative and informative way for use by a range of stakeholders. It accounts for policies and contexts and is communicated in a way that is accessible for decision-makers, easy to use and available as hard copy and interactive version.

Key messages:

- Investing in well-being and health equity drives and enables sustainable development.
- Making the case for investment in health equity requires a well-planned, evidence-informed approach.

Factors associated with activity limitation: are the risk patterns the same across Europe?

Elena Von Der Lippe

E Von Der Lippe[1]*, J Baumert*[1]

[1]Department of Epidemiology and Health Monitoring, Robert Koch-Institute, Berlin, Germany

Contact: E.vonderLippe@rki.de

Background:

The Global Activity Limitation Indicator (GALI) is part of the Minimum European Health Module and has been shown to be a valid indicator of functional limitations. The present study aims to identify determinants of GALI prevalence among adults in Europe.

Methods:

We used data from the European Health Interview Survey (EHIS) Wave 2 which included adults aged 15 years and older and was conducted between 2013 and 2015 in all European Union member states. We examined patterns regarding age, sex, education and chronic diseases. After excluding some inconsistencies in the data the sample size was 284,732 respondents from 26 countries.

When making comparisons across countries one has to bear in mind that the data was collected through different modes, the indicators were obtained through various instruments and in some countries interviews were conducted not always with the target person, but with a proxy person.

Results:

Our findings revealed that age and education are very strong determinants of functional limitation in all countries. Sex showed to be mostly non-significantly associated, however in some Eastern and Southern countries it plays a significant role. The additional factors examined showed less consistent picture. While chronic diseases with stronger disease burden were associated with higher limitation, diseases that are well treatable (like high blood pressure) showed in some countries strong associations with functional limitation while in others there was no clear relationship.

Conclusions:

Having in mind the aging of the population, the problem with the functional limitation in higher ages will increase furthermore. This is an issue which should be taken into account in health promotion policies. The role of chronic diseases and their association with disability cannot be neglected. Prevention policies should put more effort in identifying earlier the vulnerable population (e.g. less educated) and promote health care initiatives.

Key messages:

- Age and education are strong determinants of functional limitation across all European countries. Sex showed inconsistent patterns.
- Functional limitation is in general strongly associated with chronic disease. However, differences in Europe were found with regard to some specific conditions.

European Public Health Master program – public health support worldwide

Ewa Kocot

E Kocot[1], A Szetela[1], C Sowada[1], T Bochenek[1], M Lecoq[2]
[1]Institute of Public Health, Faculty of Health Sciences, Jagiellonian University Medical College, Kraków, Poland
[2]EHESP, School of Public Health, Rennes, France
Contact: ewa.kocot@uj.edu.pl

Background:

In 2006 a joint European public health master course EuroPubHealth was created by a group of European universities, coordinated by the EHESP in Rennes. The EPH Program is co-funded by the Erasmus+ Programme of the European Union.

Objectives:

One of the objective of the EPH Program is to support public health development through education of specialists from different parts of the World. To see the scope of this support, the data of candidates and students were analyzed, mainly in terms of their country of origin and background.

Results:

A total number of candidates is growing significantly: it was 319 in 2006 and 609 in 2018. In 13 intakes over 5100 candidates from 156 countries applied, 331 of them (from 77 countries) became students. Most of candidates were from Africa (42% in total and 10% from Nigeria only) and Asia (33%). Looking at students' group the structure is different - 28% students were from Europe and 25% from Asia; Africa took only 10% study places.

The most frequently occurring backgrounds of candidates and students in years 2013-2018 were medicine (over 20%), public health (about 12%) and biological sciences (10% of candidates and 16% of students), but it varied greatly depending on the origin: e.g. there were only 7% of physicians among candidates from USA, and nearly 30% among Africans and Asians. Nearly 20% students had a background not directly related to medicine and biology, so they formed very diverse groups.

Conclusions:

Over 70% EPH students came from outside Europe, over 180 public health specialists from Asia, Africa and South America were educated. Now, many of them work on public health development in countries with very high needs in this area, supporting local communities.

Key messages:

- The EPH Program helps to develop public health on all continents.
- The interest in education in public health is very big - people interested in education are from very different countries and their background is not always connected directly with human health.

From deliberative dialogue to impact: envisioning kmowledge translation

Robert Borst

O Hobden[1], RAJ Borst[1], A Al-Metleq[2], MO Kok[1,3]
[1]Health Care Governance, Erasmus School of Health Policy & Management, Rotterdam, Netherlands
[2]Higher Population Council, Amman, Jordan
[3]Amsterdam Public Health Research Institute, Vrije Universiteit Amsterdam, Amsterdam, Netherlands
Contact: borst@eshpm.eur.nl

Background:

The previous decades of research have contributed tremendously to the improvement of health. Nonetheless, problems remain regarding the use and relevance of public health research. Knowledge translation methods, such as deliberative dialogues, are believed to increase the use and relevance of such research. However, little is known about how they increase the impact of public health research. This study sought to trace the impact of deliberative dialogues through an actor-scenario approach. Actor-scenario mapping asks key actors to describe how and by whom research findings may potentially be used. This allows for constructing more concrete action plans.

Methods:

This study used a qualitative case-study design with semi-structured interviews, participant observation, and a survey. The study focused on a Jordanian deliberative dialogue organised in April 2019. Interviews were conducted with 15 key stakeholders before and after the dialogue. Observations and surveys were collected during the dialogue. An abductive approach to thematic analysis was used to arrive at key themes for the report.

Results:

The results show that dialogue participants found it difficult to propose concrete scenarios for action. They described that the sensitive nature of some research topics impairs action. Additionally, participants proposed that research funding should be earmarked for concrete actions. Overall, their scenarios proposed that high-level decision makers maintain involved in the knowledge to action process. Some participants mentioned that the articulation of scenarios for action contributes to research impact, since researchers usually do not engage with potential users.

Conclusions:

Actor-scenario mapping is an innovative way of understanding how deliberative dialogues increase the impact of public health research. This scenario approach can inform the organisation of deliberative dialogues by actors such as EVIPNet.

Key messages:

- Actor-scenario mapping can trace the impact of deliberative dialogues.
- The scenario approach can better align the dialogues with policy and practice.

The role of micro-insurance in the field of public health

Marija Jevtic

T Novakovic[1], M Jevtic[2,3], Lj Popović[1], Dj Ćosić[1]
[1]Faculty of Technical Sciences, University of Novi Sad, Novi Sad, Serbia
[2] Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia
[3]Institute of Public Health of Vojvodina, Novi Sad, Serbia
Contact: marija.jevtic@uns.ac.rs

Issue/problem:

It is recognized that is very important to have an instrument to mitigate risks and reduce the vulnerability of poor and low-income households, especially in disasters. Health risks are often identified by the poor people as the greatest and costliest risks they face. Millions of people worldwide fall into poverty as a result of excessive healthcare costs because the state doesn't provide them health insurance. Health problems not only impact household budget, but also reduce the productivity and reduce the opportunity for growth. Therefore the reform of social systems poses a considerable challenge.

Description:

In order to remedy the situation, global actors like World Health Organization (WHO, International Labour Organization (ILO), the World Bank (WB) advocate for a special category of insurance, health micro-insurance (HMI), as a medium term solution for health care financing, that tends to access equitable and quality health care. HMI was created to promote insurance coverage among economically vulnerable sections of society. It is one of the potential ways that might provides the protection of low-income people against specific perils in exchange for regular premium payment proportionate to the likelihood and cost of the risks involved.

Results:

As a health care financing mechanism, HMI has a short history, but offers the following benefits: it can improve the access of certain vulnerable populations to healthcare, develop more suitable services, facilitate the participation of civil society and limit fraud, educate populations about social security.

Lessons:

This instrument has not been conceptualized to compete or replace public social protection. Rather, it is most effective when embedded into a comprehensive social protection framework which includes informal, private and other risk management strategies of preventive measures, mitigation and suitable coping strategies.

Key messages:

- HMI can mitigate the risks of population and groups, ill health and provides hope that the poor will receive reliable and adequate access to affordable health care.
- HMI can be seen as a tool for better public health in vulnerable and poor communities.

Citizens' perspectives on genomic sciences and direct-to-consumer genetic tests: systematic reviews

Ilda Hoxhaj

I Hoxhaj[1], J Stojanovic[1], A Tognetto[1], M Sassano[1], GE Calabrò[1], S Boccia[1,2]
[1]Section of Hygeine, Institute of Public Health, Rome, Italy
[2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy
Contact: ilda.hoxhaj1@unicatt.it

Background:

Past decades have witnessed enormous progress in the field of genetics and genomics, and yet a low level of awareness among general public has been described. Our aim was to explore the general populations' knowledge, attitudes and behaviors towards genomic sciences, with a focus on direct-to-consumer genetic tests (DTC-GTs). DTC-GTs are genetic tests ordered directly by the public, without the involvement of a healthcare provider.

Methods:

Two systematic reviews were conducted related to citizens' knowledge, attitudes and behaviours. Firstly, we updated the current literature on DTC-GTs by searching PubMed, Web of Science, Embase, Scopus and Google Scholar. Studies published in English from October 2014 to January 2019, conducted in Europe were included. Secondly, we searched PubMed, Web of Science and Embase to review English and Italian studies on genomic sciences from 2003 to 2019.

Results:

In the systematic review on DTC-GTs, we included six studies from Italy, Greece, Germany, The Netherlands and Switzerland. European citizens had an overall low level of awareness and a very small proportion of them had personal experience with DTC-GTs. More than half of the participants were interested in undergoing a DTC-GT, mainly for knowing the risk predisposition to a common disease such as cancer or cardiovascular disease. Concerns were raised about tests' validity and utility as well as data privacy. In the systematic review on genomic sciences, 55 studies were included. The data extraction process is still in progress and our preliminary results indicate low levels of awareness on genomics.

Conclusions:

Our findings showed that European citizens have a modest level of awareness and a high interest in DTC-GT. Understanding the citizens' perspectives toward genomic sciences may contribute to the development of educational programs related to their needs.

Key messages:

- European citizens expressed modest levels of awareness and high levels of interest in DTC-GTs, mainly for knowing the risk predisposition to common diseases.
- European citizens are concerned with the data privacy and DTC-GT's validity and utility.

Use of personal protective equipment among farmers in Nebraska, Lithuania, Latvia, and Slovenia

Chandran Achutan

C Achutan[1], L Girdžiūtė[2], G Vasiliauskas[2], K Kampuss[3], J Starič[4], R Rautiainen[1]
[1]College of Public Health, University of Nebraska Medical Center, Omaha, USA
[2]Agriculture Academy, Vytautas Magnus University, Kaunas, Lithuania
[3]Faculty of Agriculture, Latvia University of Life Sciences and Technologies, Jelgava, Latvia
[4]Veterinary Faculty, University of Ljubljana, Ljubljana, Slovenia
Contact: cachutan@unmc.edu

Background:

Farmers in the U.S. and in Europe are at a high risk for injury and illness. Farmers have an increased risk of respiratory disease, noise-induced hearing loss, skin disorders, and eye injuries. Many of these health risks can be prevented or reduced through proper use of personal protective equipment (PPE). However, studies show low compliance of PPE use among farmers. The purpose of this study was to identify barriers to wearing PPE, and current health and safety training as potential targets for future intervention, in farmers in Nebraska, Lithuania, Latvia, and Slovenia. The European Cooperation in Science and Technology and the Central States Center for Agricultural Safety and Health collaborated on this study.

Methods:

We administered a 7-item questionnaire to 57 farmers in Nebraska (n = 10), Lithuania (n = 22), Latvia (n = 10) and Slovenia (n = 15). The farmers primarily grew crops (corn, soy) and some raised livestock.

Results:

We found that gloves, respirators, and safety glasses were the PPE most commonly worn; use of face shields were only reported in Nebraska and Lithuania. Only 45% reported wearing PPE always when they needed them. In Nebraska and

Latvia, most farmers reported not wearing PPE because they are not readily available although they have them on the farm; in Lithuania and Slovenia, farmers cited time to don PPE and discomfort as primary reasons. The percentage of farmers who reported receiving training on the selection, use, and maintenance of PPE varied widely-13% in Nebraska, 14% in Lithuania, 40% in Latvia, and 67% in Slovenia. Farmers purchased PPE over the internet, supermarkets, and agricultural cooperatives.

Conclusions:

This study provided an opportunity to understand current perceptions of PPE use and challenges, among a cross section of farmers in the U.S. and Europe. We recommend enhancing training through creative modules to address the needs of farmers.

Key messages:

- By identifying why farmers do not always wear PPE, we can design effective interventions to overcome this barrier; by knowing where they purchase them, we can provide education at these venues.
- This study is a joint collaboration between U.S. and European researchers. This global cooperation has highlighted some similarities but also differences within European countries.

Bridging the Atlantic Projects: nursing students learning to work globally with vulnerable groups

Maryellen Brisbois

M Brisbois[1], *H Pereira*[2]
[1]Community Nursing, University of Mass Dartmouth, Dartmouth, USA
[2]School of Health, University of the Azores, Ponta Delgada, Portugal
Contact: mbrisbois@umassd.edu

Background:

Providing care for vulnerable groups requires the development of competencies such as openness to diversity, cultural sensitivity and equity. Health education institutions face the challenge of preparing students in developing these competencies in a global world. The Bridging the Atlantic program, a partnership between the University of the Azores (Portugal) and the University of Dartmouth (MA, US) in the field of Community Nursing, was created to respond to this need. Students from both universities work collaboratively to develop competencies in providing health care to vulnerable groups based on the IN-STEP (International Student Exchange Partnership) Framework.

Objectives:

(i) to contribute to the improvement of the health status of vulnerable groups; (ii) to develop clinical competencies addressing vulnerable groups among nursing students.

Results:

Between 2015 and 2019, 110 students were involved in health promotion projects carried out with aggregates of elderly immigrants, deportees, fishermen, children from low income schools. The benefits for the vulnerable groups were mainly related to raise awareness in the communities concerning the problems these groups face. Regarding the impact of the program on training, students reported they developed competencies on: (i) understanding cultural differences; (ii) recognizing different health care systems; (iii) reconsidering the role of the nurse; (iv) building teamwork; (v) integrating theory into practice; and, (vi) peer mutual learning.

Conclusions:

Engaging in health promotion projects globally through collaborative efforts seemed to be effective for the improvement of health of vulnerable groups and student development.

Key messages:

- Universities need to deepen the development of competencies in students to intervene with vulnerable groups in a global world.
- Although designed for nursing students in a community context, this model can be used in similar ways by other fields of health or social intervention.

Scale-up integrated care for diabetes and hypertension in Cambodia, Slovenia and Belgium

Kerstin Klipstein-Grobusch

K Klipstein-Grobusch[1], *TA Poplas Susič*[2], *I Por*[3], *E Wouters*[4], *I Makivič*[2], *V Te*[3], *M Martens*[5], *K Danhieux*[4], *R Remmen*[4], *J Van Olmen, on behalf of the SCUBY consortium*[5]
[1]University Medical Center Utrecht, Utrecht, Netherlands
[2]Community Health Center Lubljana, Lubljana, Slovenia
[3]National Institute of Public Health, Phnom Penh, Cambodia
[4]University of Antwerp, Antwerp, Belgium
[5]Institute of Tropical Medicine, Antwerp, Belgium
Contact: k.klipstein-grobusch@umcutrecht.nl

Many countries struggle to find the best way to treat hypertension (HT) and type 2 diabetes (T2D). As a result, many patients receive suboptimal care, especially vulnerable groups in society. The SCale up Integrated Care for diaBetes and hYpertension (SCUBY) project addresses this important societal issue, by examining the scale-up of existing evidence-based interventions for the control of HT and/or T2D.

The study undertaken in countries with very different health systems, i.e. a developing health system in a low-middle income country - Cambodia; a former socialist high-income country with a centralised health system - Slovenia; and a Western European federal country with a decentralised system-Belgium, develops, implements and assesses roadmaps for the scale-up of an integrated chronic care package (ICP). The ICP consists of (a) identification of people with HT or T2D, (b) subsequent treatment in primary care services, (c) health education, (d) self-management support to patients and caregivers, and (e) collaboration between caregivers. Analysis of the organisational capacity to scale-up the ICP for T2D and HT and to assess contextual barriers and facilitators to do so, informs the development of the roadmaps. Implementation and evaluation of the 3 roadmaps, one per country, assesses the impact on health outcomes and quality of care through the scale-up of the ICP aimed to contribute to sustainable coverage of T2D and HT interventions for more people in each country. The project is innovative because it compares different scale-up strategies for a contextualised common intervention package. It applies the conceptual insights from scale-up science to the field of non-communicable diseases and involves policy-makers, professionals and patients to ensure local relevance and impact. It will generate new knowledge on how to scale-up the ICP for T2D and HT in diverse contexts. The lessons on scale-up will benefit policy-makers in countries with similar contexts.

Key messages:

- Innovative strategies are needed to scale up integrated chronic care for non-communicable diseases.
- The SCUBY project develops, implements and assesses roadmaps for the scale-up of an integrated chronic care package for hypertension and diabetes.

Strategies and measurement for global health governance assessment: a 5-years mixed review

Gianfranco Damiani

G Damiani[1,2], *V Pettinicchio*[3], *R Markovic*[4], *L Rosi*[5]
[1]Università Cattolica del Sacro Cuore, Rome, Italy
[2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy
[3]Local Health Unit Rome 1, Rome, Italy
[4]Institute of Public Health of Serbia, Belgrade, Serbia
[5]Italian National Institute of Public Health, Rome, Italy
Contact: gianfranco.damiani@unicatt.it

Global health governance is defined as the use of institutions, rules and processes ‘‘to deal with challenges to health that require cross-border collective action to be addressed effectively’’. Several studies on this have been published, but there is no consensus about the measure of its various aspects. The aim of this study was to search for strategies used by healthcare systems to evaluate their care in global settings and for shared indicators to assess global health governance worldwide.

This systematic analysis of qualitative and quantitative studies was conducted according to the Population-Intervention-COntext model and the Population-Intervention-

Comparison-Outcome models, using search string ''global health and governance and assessment'', from 2014 to 2018 (in biennium 2013-14 WHO and others identified health governance as a global priority). Articles that reported quantitative and/or qualitative evaluation on global health governance were included.

Outcomes were screened by title and abstract, and then by full texts in order to assess eligibility.

From a total of 98, six studies met inclusion criteria. 4 main strategies of global health governance were identified: intersectoral policies (demographic factors, sanitation practices, housing characteristics and social behaviors); food and nutrition, caring to strengthen country-owned governance capacity (high levels of governance are associated with signing up initiatives for undernutrition prevention, OR = 30); disability and rehabilitation, crucial for realization of the right to health; risk factors control and non-communicable disease prevention (tobacco control).

Two set of indicators were found: an expert-informed framework for assessing rehabilitation and a set of primary data sources to evaluate nutrition in fragile countries. Although lots of evidence in literature about globalization, only few areas are adequately measured. Literature about this topic should pay attention to assessment.

Key messages:

- In literature, four local areas were identified having perspective of global health governance: intersectoral policies, nutrition, rehabilitation and non-communicable disease prevention.
- For two of these areas, nutrition and rehabilitation, shared patterns of indicators were found, from primary data sources and expert consensus.

Acceptability and utilization of evidence for decision-making: helminth control, sub-Saharan Africa

Georgina Pearson

G Pearson[1,2], *B D'Souza*[2], *C Fergus*[2,3]
[1]Population Health Research Institute, St George's, University of London, London, UK
[2]Firoz Lalji Centre for Africa, London School of Economics and Political Science, London, UK
[3]Department of International Development, London School of Economics and Political Science, London, UK
Contact: gpearson@sgul.ac.uk

Background:

Public health practitioners are part of a larger global health system, responsible for the implementation of disease-specific health interventions, largely financed by external actors through a variety of mechanisms. Emphasis on the need for evidence-informed decision-making often includes rhetoric for the localization of this approach to assist practitioners in resource allocation. In practice its realisation is challenging. This research addresses the following: what are the evidence needs of local public health practitioners? How acceptable are, for example, modeled disease estimates? What decision-making processes occur for implementation? How do evidence and decision-making processes interact?

Methods:

Examining mass drug administration (MDA) for schistosomiasis and soil-transmitted helminths (STH) in the African Great Lakes region (Kenya, Malawi, Tanzania and Uganda), we use qualitative approaches to collect data, including a series of 4 workshops with district- and national-level MoH personnel, key informant interviews and e-survey questionnaires from a sample of relevant local and global organisations including NGOs. Coded data are analysed thematically.

Results:

Preliminary results provide important insights into the sources, types and format of evidence which local public health practitioners find acceptable and useful for decision-making when implementing disease control measures.

Conclusions:

A variety of factors influence local level decision-making with implications for policy aimed at disease control, such as MDA for schistosomiasis and STH, and global health policy and practice more broadly. First, processes of decision-making at different localities are heterogenous and evidence needs of local practitioners are not well understood. Second, evidence development and knowledge synthesis on health interventions are rarely linked in ways that feedback and respond to local implementation, decision-making practices and public health practitioners.

Key messages:

- Evidence needs of local public health practitioners need to be accounted for when producing and synthesising evidence.
- Multiple factors influence local level decision-making with implications for public health disease control policy.

Implementation research to evaluate an educational intervention for people who inject drugs

Salim Mezaache

P Roux[1,2], *C Magen*[1,2], *R Stranz*[3], *E Schatz*[4], *L Verdes*[8], *A Curado*[5], *T Tsiakou*[6], *E Roy*[7], *P Carrieri*[1,2]
[1]Faculty of Medicine and Health Sciences, INSERM, Marseille, France
[2]ORS PACA, Marseille, France
[3]AIDES, Pantin, France
[4]Correlation Network, Amsterdam, Netherlands
[5]GAT, Lisbon, Portugal
[6]PRAKSIS, Athens, Portugal
[7]Faculty of Medicine and Health Sciences, University of Sherbrooke, Longueil, Canada
[8]ARAS, Bucarest, Romania
Contact: salim.mezaache@inserm.fr

Objective:

In the context of disseminating harm reduction (HR) programmes in Europe, the Eurosider project aims to study the transferability of an effective educational intervention for people who inject drugs (PWID) to four European countries (Bulgaria, Greece, Portugal and Romania). This intervention, entitled Individually-Tailored Support and Education for Safer Injection (ITSESI), has been shown to reduce HIV-Hepatitis C Virus (HCV) risk practices by offering educational supervision during all phases of the injection sequence, from pre- to post-injection.

Methods:

The project employs mixed methods and implementation science. The exploratory first step used qualitative interviews and other available data in each country. The second step consists in implementing and evaluating the intervention using a 6-month study conducted among 300 PWID enrolled in the 4 countries. They are interviewed at baseline and at 6 months. The third step will consist in designing, promoting and disseminating all the tools necessary to transfer ITSESI at the European level.

Results:

Results from the exploratory phase highlighted two main determining factors for the feasibility of implementing ITSESI: funding and a repressive legal context. Preliminary results from a quantitative analysis of data from the second step will provide a baseline description of the 300 PWID.

Discussion:

Findings to date indicate that an exploratory phase is crucial to adapt and transfer the intervention to local contexts and to evaluate it. More globally, the Eurosider project will 1) help understand each local context to adapt the intervention accordingly; 2) assess the feasibility and effectiveness of ITSESI in different contexts; 3) promote and disseminate tools and training to implement the intervention at the European level.

Key messages:

- People who inject drugs in European countries report HIV-HCV risk practices and adequate prevention should be provided.
- The implementation of an innovative educational intervention for people who inject drugs may be one response but requires to take into account contextual factors: funding and repressive drug policy.

DE Maternal, child and adolescent public health

Stress perceived by pregnant and decision-making factors of maternal caesarean section request

Sébastien Riquet

S Riquet[1], *C Coste*[1], *M Monguillon*[1], *C Zakarian*[1]
[1]UFR SMPM, Aix-Marseille Université, Marseille, France
Contact: sebastienriquet@yahoo.fr

Background:

Pregnancy is a time of psychological vulnerability which can generate intense stress. This represents a maternal and child public health problem. Prenatal stress has harmful impacts on the foetus, the newborn and can cause an increased maternal request for caesareans sections, with nonmedical grounds. The perceived level of prenatal stress factors was assessed in women, as well as mothers' incentives and decision-making factors for a caesarean section on maternal request.

Methods:

A descriptive study on 203 pregnant women, then a comparative study between primiparas (n = 72) and multiparas (n = 131) were carried out with the Antenatal perceived stress inventory. Incentives and decision-making factors for a caesarean on the mother's demand were studied by in-depth interviews with primiparas mothers (n = 16) who had made this choice.

Results:

The perception of stress level during pregnancy is higher at the first quarter regarding the foetus' health, medical and obstetric risks and reverses with the perception of projections linked to giving birth at the last quarter. Primiparas are significantly ($p < 0.001$) more stressed. All the elements of the three assessed factors are very significantly ($p < 0.001$) correlated for the whole population. Among them, 75% choose a caesarean section on maternal request during the first quarter. This choice is confirmed at the end of the second quarter or during the third one for 50% of them, with a one-month time to think for 58.3% of them. The main incentives are tokophobia (66.7%) and preserving the baby's health (50%).

Conclusions:

Pregnancy causes important stress, which is pronounced in primiparas. In France, these results speak in favour of screening tokophobia and an earlier start of birth and parenthood preparation classes in order to handle stress from the first quarter of pregnancy, when medical and prenatal exams are initiated. Birth preparation should be taken on at the last quarter.

Key messages:

- Investigate stress perceived and identification incentives and decision-making factors of maternal caesarean section request it's a solution to building bridge for solidarity with tokophobic women.
- The relation enter stress perceived by pregnant women and decision-making factors of maternal caesarean section request, represents a maternal and child public health problem.

Induced abortions in Estonia, 1992-2017: registry-based study

Piret Veerus

P Veerus[1]
[1]Department of Epidemiology and Biostatistics, National Institute for Health Development, Tallinn, Estonia
Contact: piret.veerus@tai.ee

Background:

In Estonia, termination of pregnancy is allowed until 12 gestational weeks on request or for medical reasons, and until 22 gestational weeks only for women under 15 or over 45 years of age and for severe medical illness of the mother or the fetus. Information about all induced abortions is collected in the central digital Abortion Registry since 1996. The source document for collection of data is the Abortion Card which is filled in for every abortion that has taken place in a health care institution by all health care institutions (incl. private doctors) who do abortions or provide medical care to women who have had an abortion. The choice of contraceptive devices is large and their price is affordable. Sexual education is included in school curriculum. Councelling about contraception is free for all citizens until 25 years of age. Termination of pregnancy is free only for medical reasons, in other cases there is a small fee.

Methods:

Data for the analysis was obtained from the Estonian Abortion Registry.

Results:

The total number of induced abortions in Estonia decreased from 25803 in 1992 to 4017 in 2017. The abortion rate per 1000 women aged 15-49 declined from 69.6 in 1992 to 14.0 in 2017. The abortion rate among women under 20 has declined from 43 in 1996 to 10.8 in 2017. The abortion rate has always been the highest in the age group from 20 to 24 years. Abortion rates in 2017 varied in different counties from 7.4 to 17.3. In 1996, 97.8 % of preganancies were terminated surgically, in 2017, only 22.3%.

Conclusions:

Although induced abortion is legal and not restricted in Estonia, the abortion rate has fallen rapidly due to sexual education at school, free youth councelling services and easily available contraceptive devices. Abortion Registry database is a valuable source of information for evaluating and planning public health interventions. Regional differences in abortion rates deserve further interventions.

Key messages:

- Abortion rates in Estonia have fallen rapidly due to sexual education, free councelling and available contraceptive devices.
- The Estonian Abortion Registry is a valuable source of information for public health interventions.

The impact of social media misused and behavior problems among adolescent in Thailand

Punnita O-ium

P O-ium[1]
[1]Department of Military and Community Medicine, Phramongkutklao College of Medicine, Bangkok, Thailand
Contact: Praewa.punn@gmail.com

Introduction:

Recent increased in the prevalence of behavioral problems among young adults has coincided with the raised of popularity of Internet usage including handheld technologies, electronic game and social media among adolescent. However, these information in Thailand is limited. Therefore, this study aim to investigate the association between social media misused and behavioral problems among adolescent in Thailand.

Materials and methods:

The cross-sectional was conducted at 7 public schools located in Central of Thailand in December 2018. The behavioral problems were assessed by using the Strengths and Difficulties Questionnaire (SDQ). Multiple logistic regression analysis was used to identify the risk factors associated with the behavioral problems.

Results:

The total of 1,118 were enrolled into the study. The prevalence of the social media misused and behavioral problems were 85% and 18.5%, respectively. The prevalence of the subscale behavioral problems were peer problem (21%), emotional problem (19%), hyperactivities (10%) and conduct problem (4%). The independent factors associated with behavioral problems were include sleep problem (OR = 3.3, 95%CI =

2.1-5.1), prosocial behavior (OR = 0.4, 95%CI =0.3-0.6), social media misused (OR = 2.5, 95%CI =1.7-3.8), Facebook addiction (OR = 1.8, 95%CI = 1.1-3.0) and Line addiction (OR = 2.8, 95%CI = 1.5-5.1).

Conclusions:

This study highlight the association between the social media misused and high prevalence of behavioral problems among adolescent in Thailand. The information of the potential risk factors should be inform to all stakeholders for develop and implement the effective intervention for young adults in Thailand.

Key messages:

- The association between the social media misused and high prevalence of behavioral problems among adolescent in Thailand.
- The information of the potential risk factors should be informed to develop and implement the effective intervention for young adults in Thailand.

Screenings for children: international programmes & recommendations from evidence-based guidelines

Roman Winkler

R Winkler[1], *I Reinsperger*[1]
[1]Ludwig Boltzmann Institute for Health Technology Assessment, Ludwig Boltzmann Gesellschaft, Vienna, Austria
Contact: roman.winkler@hta.lbg.ac.at

Background:

Children and adolescents are in general a healthy population group. However, they are exposed to a number of morbidities (physical illnesses and mental disorders) and social burdens (e.g. poverty, violence). In Austria, there are currently no routine screenings for children older than 6 years. The project aimed at providing an overview of international screening programmes and of recommendations from evidence-based guidelines for 6 to 14 years old children.

Methods:

The overview of screening practices in nine selected (mostly European) countries is based on an (Internet) hand search and expert contacts. For the guideline overview, we conducted a search in guideline databases and on websites of institutions.

Results:

We identified four main screenings that were predominantly offered in the analysed countries: screenings of body weight & height, hearing & vision disorders, dental disease and mental disorders. The services are provided in school and/or in doctors' practices, involving physicians and/or nurses. 50 evidence-based guidelines from 16 institutions met our pre-defined inclusion criteria. We identified recommendations for 24 diseases or risk factors. We found most recommendations on screening for overweight and dental disease. Further guidelines addressed infectious diseases, mental disorders, health and risk behaviour, and counselling.

Conclusions:

The results are now used as a basis for discussion for the development of a new screening programme in Austria. The overview provides an international and evidence-based view. However, social determinants of health, such as education and living conditions, were hardly considered in the identified screenings, but should be increasingly addressed in a comprehensive programme.

Key messages:

- Screenings for overweight and dental disease were central in both the selected countries' programmes and the guideline recommendations.
- Comprehensive programmes should not only focus on physical parameters, but should also take into account the social determinants of health.

Perceptions of youth healthcare professionals of the concept Positive Health in the Netherlands

Cindy De Bot

CMA de Bot[1], *E van Meerten*[2], *JAJ Dierx*[1]
[1]Living in Motion Research group, Avans University of Applied Sciences, Breda, Netherlands
[2]Bachelor of Nursing, Avans University of Applied Sciences, Breda, Netherlands
Contact: cma.debot@avans.nl

Background:

Based on public health professionals' opinions, Huber et al. (2011) described health as a dynamic concept that has the potential to increase or decrease depending on contextual factors, yet with the broadness as the WHO definition. She proposed defining health 'as the ability to adapt and self-manage, in the light of physical, emotional and social challenges of life'. Healthcare professionals are exploring how the new concept can be further specified for various fields of healthcare. This study examines the perceptions of youth healthcare professionals to Positive Health and to what extent they experience this concept in current working practice.

Methods:

A mixed-methods research has been used; both quantitative and qualitative data have been collected. A questionnaire survey (n = 97) has been done and semi-structured interviews (n = 12) have taken place to question youth healthcare professionals in public health about the positive health concept.

Results:

Youth healthcare professionals find all the dimensions of positive health important. However, not all dimensions of positive health are suitable in daily practice of youth healthcare professionals in public health. The dimension 'Quality of life' is seen as the most important dimension in terms of positive health. The concept of positive health can be applied within the workfield of youth healthcare professionals. However, the implementation of new concept should be explored.

Conclusions:

This study shows that youth healthcare professionals have a positive attitude towards Positive Health. Youth healthcare professionals consider the all the dimensions important and also embed the aspects of it in their daily practice. However, the implementation of new concept should be explored.

Key messages:

- The Positive Health concept in youth healthcare care is promising.
- Positive Health gives a broader look at health.

Health promotion around the birth

Raimund Geene

R Geene[1]
[1]Berlin School of Public Health, ASH, Berlin, Germany
Contact: raimund.geene@charite.de

Background:

With the "Child Protection Act" in 2012, the Prevention Law in 2015 and the new health goal 'Health around Birth' in 2017, the framework conditions for health promotion and prevention in pregnancy have improved. This takes into account the fact that health behavior is essentially determined by embryonic and early childhood experiences in families.

Methods:

First: Analyzing the family-related legal regulations by Early Helps and the Prevention Act as well as the health goal "Healthy Birth"; Second: Analyzing data from 153 interviews with socially disadvantaged mothers; Third: Collecting mothers' impressions (in citations) about physiological, psychological and social coping factors; Fourth: Analyzing conceptually and within different phases of pregnancy (orientation-, self-conception-, subject conception-, anticipation- and birth phase) and postnatal phases (postpartum, family becoming, stabilization and socialization to society) phase-specific prevention needs and potentials identified as well as examples of health promotion.

Results:

Pregnancy and becoming a family are associated with different coping requirements, which should be treated specifically according to phases and social conditions. A tailored analysis provides a variety of methods and approaches for health promotion, which can be offered via setting-approaches or in individual counseling and support. They can be described as parts of family health promotion, which should be designed as a joint task of the health service and child and youth welfare as well as other local actors.

Discussion:

Family health promotion is a complex challenge for the actors in the care, in the social area and in the control levels. It requires an independent, scientifically justified intervention approach with method programs and institutional assignments.

Key messages:

- Pregnancy and becoming a family are associated with different coping requirements.
- It requires an independent, scientifically justified intervention approach with method programs and institutional assignments.

Collaboration between midwives and dietitians in improving dietary intake of low SES women

Sabina Super

S Super[1], Y Beulen[1], A Wagemakers[1]
[1]Health and Society, Wageningen University, Wageningen, Netherlands
Contact: sabina.super@wur.nl

Background:

A healthy dietary intake during pregnancy is important for maternal and child health. However, pregnant women with a low socioeconomic status (SES) are less likely to adhere to nutrition guidelines as compared to high SES groups. Midwives in the Netherlands experience limited opportunities to provide nutrition advice. Dietitians could play a role in providing nutrition advice to pregnant women, but collaborations between midwives and dietitians are limited. Therefore, this study aimed to investigate the opportunities and barriers for collaboration between midwives and dietitians in antenatal care for low SES women.

Methods:

Questionnaires were administered amongst 134 dietitians to examine experiences of providing nutritional advice to pregnant women. Four focus groups were organised with midwives (2x) and dietitians (2x) to explore opportunities and barriers for collaboration.

Results:

Questionnaire results indicated that 73% of the dietitians like to see pregnant women more often in their practices and 78% feels the necessity to strengthen the collaboration with midwives. The focus groups showed that dietitians and midwives wish to strengthen the collaboration, but they also experience barriers: a focus on food risks rather than healthy nutrition in antenatal care, lack of referral procedures for women without medical necessity to see a dietitian, negative connotations with referring women to dietitians, and lack of time to discuss nutrition in consults by midwives.

Conclusions:

Midwives and dietitians recognise the importance of strengthening collaborations, but in order to do so, several challenges need to be overcome. In a follow-up of this study, pressure cooker sessions will be conducted to design an integral strategy in antenatal care to empower women to improve dietary intake.

Key messages:

- There is a great potential to strengthen collaborations between midwives and dietitians in antenatal care to empower low SES pregnant women to improve dietary intake.
- Several barriers need to be overcome to design in an integral strategy in antenatal care to improve the dietary intake of low SES prengant women.

Assessment of Adolescent and Youth Friendly Health Services in Sri Lanka using WHO's '4S' Framework

Nuwan Wickramasinghe

N Wickramasinghe[1], C Vithana[2], A Lokubalasooriya[3], N Hemachandra[4]
[1]Department of Community Medicine, Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka, Anuradhapura, Sri Lanka
[2]Adolescent and Youth Health Unit, Family Health Bureau, Colombo, Sri Lanka
[3]School Health Unit, Family Health Bureau, Colombo, Sri Lanka
[4]RMNCAH & Nutrition, WHO Country Office for Sri Lanka, Colombo, Sri Lanka
Contact: nuwick74@yahoo.com

Background:

The Adolescent and Youth Friendly Health Services (AYFHS) in Sri Lanka (SL) are provided via three service models, viz., hospital-based, field-based and centre-based. This study assessed the implementation status of AYFHS in SL.

Methods:

A panel of experts conducted the review by adopting a participatory approach. Policies and supporting documents were collected from the relevant sectors of the Ministry of Health using electronic and manual search and by visiting institutions/resource persons. The strengths and weaknesses of the AYFHS were identified using the WHO's '4S' Framework consisting strategic information (S1), supportive evidence-informed policies (S2), strengthening services for adolescents (S3) and strengthening collaboration with other sectors (S4).

Results:

While recent development of guidelines, standards and protocols in line with WHO/UNAIDS 'Global Standards for Quality Health-care Services for Adolescents' was the main strength on S1, gaps in timeliness, completeness and accuracy of the data; and the gaps in effective utilization of sub-national level data addressing area specific problems were the main weaknesses. On S2, SL has a strong, supportive policy environment to promote adolescent health. Lack of coherence in existing health related policies was the main gap. A comprehensive health care package was a strength on S3, while difficulty in reaching the vulnerable groups, curative service oriented service package and underutilization of the health services by adolescents were the weaknesses. On S4, lack of sustained political commitment identifying adolescent health as a priority development issue across multi-stakeholders and their silo mentality to maintain the accountability/ownership of cross-cutting programmatic activities were the weaknesses.

Conclusions:

Despite numerous imposing challenges, with mainstreaming and constructive monitoring, the AYFHS in SL will remain as one of the best adolescent health programmes in the region.

Key messages:

- Assessment of Sri Lankan AYFHS according to the WHO's '4S' Framework revealed multiple strengths such as updated guidelines, supportive policy environment and comprehensive care package.
- Despite numerous imposing challenges, with mainstreaming and constructive monitoring, the AYFHS in SL will remain as one of the best adolescent health programmes in the region.

School Health Programme in Sri Lanka: Assessment using WHO's '4S' Framework

Nuwan Wickramasinghe

N Wickramasinghe[1], A Lokubalasooriya[2], C Vithana[3], N Hemachandra[4]
[1]Department of Community Medicine, Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka, Anuradhapura, Sri Lanka
[2]School Health Unit, Family Health Bureau, Colombo, Sri Lanka
[3]Adolescent and Youth Health Unit, Family Health Bureau, Colombo, Sri Lanka

[4]RMNCAH & Nutrition, WHO Country Office for Sri Lanka, Colombo, Sri Lanka
Contact: nuwick74@yahoo.com

Background:

Sri Lanka has one of the oldest school health programmes (SHP) in the region, which was started in 1918, and at present caters for 70% of adolescents in the country. This study assessed the implementation status of the Sri Lankan SHP.

Methods:

This review was conducted by a panel of experts adopting a participatory approach. Policies and supporting documents were collected from the relevant sectors of the Ministry of Health and Ministry of Education using electronic and manual search and by visiting institutions/resource persons. The WHO's '4S' Framework; consisting of strategic information (S1), supportive evidence-informed policies (S2), strengthening services for adolescents (S3) and strengthening collaboration with other sectors (S4); was used as the guiding framework to analyse the strengths and weaknesses of the SHP.

Results:

Having a comprehensive national health information system was the main strength on S1, gaps in timeliness, completeness and accuracy of the data, and the lack of evidence on perceived health needs of school children were the main weaknesses. On S2, Sri Lanka has a strong unifying policy platform supportive of the SHP, but the timeliest need is to finalise the School Health Policy. More than 90% island-wide coverage of school medical inspection was the main strength on S3, while focusing more on physical health and less emphasis on promoting mental health in the existing service package and gaps in the referral/follow-up were the weaknesses. On S4, school staff focusing more on achieving academic-related outcomes and focusing less on health-related activities, undue media and industry influence hindering the promotion of healthy behaviours in school settings were the main challenges.

Conclusions:

Despite several emerging challenges, the SHP in Sri Lanka is one of the best school health programmes in the region with more than 90% island-wide coverage of health services.

Key messages:

- The SHP in Sri Lanka, which is one of the oldest and the best school health programmes in the region, caters for 70% of adolescents in the country.
- Assessment of Sri Lankan SHP according to the WHO's '4S' Framework revealed multiple strengths such as comprehensive national health information system and high island-wide coverage.

Determinants of health and cancer: investigating conceptions of children aged 6 to 11

Maéliane Deyra

MD Deyra[1], CG Gay[1], FP Pizon[1], LG Gerbaud[1]
[1]Université Clermont Auvergne, Institut Pascal, Clermont-Ferrand, France
Contact: maeliane.deyra@etu.uca.fr

Context:

Qualitative data on how children and adolescents view their health and its determinants are relatively few at the international level. This research is therefore part of a comprehensive and open-minded approach to better describe how elementary school children perceive the determinants of health and cancer.

Objectives:

Our main objective is to map, from a multiphase qualitative protocol, the conceptions and systems of conceptions on the determinants of health and cancers perceived within a 6 to 11 age group.

The secondary objective is to analyze our ability to collect these healthy conceptions from children.

Methodology:

Four different tools were used in four schools for 320 students: (1) ''photo expression'', (2) ''QC (Questions / Certainties)'', (3) ''photo narration'' and (4) ''focus group''. This open and exploratory method, combining the use of photographs and focus groups, provided data on the experiences, stated practices and knowledge of each student. The mobilization of image mediation methods plays an essential ethical role by ensuring the distance between the theme and the child. The informative value of data from qualitative collection tools coupled with a mixed analysis methodology (qualitative and quantitative) allows us to collect dense and efficient data needed to understand the perception of determinants by elementary school students.

Conclusions:

This study identifies promising methodological leads thanks to the complementarity of the different phases mobilized. It also provides us with elements of methodological understanding that can contribute to the development of prevention tools as part of the school health education journey.

Key messages:

- Map, from a multiphase qualitative protocol, the conceptions and systems of conceptions on the determinants of health and cancers perceived within a 6 to 11 age group.
- Analyze our ability to collect these healthy conceptions from children.

eDelphi survey to shape the content of a digital resource to enhance parental health literacy

Ourania Kolokotroni

O Kolokotroni[1,2], E Hadjigeorgiou[3], C Gourounti[4], V Christodoulides[2], A Sarantaki[4], C Nicolaou[3], K Lykeridou[4], M Karanikola[3], C Kouta[3], N Middleton[3]
[1]Department of Primary Care and Population Health, University of Nicosia Medical School, Nicosia, Cyprus
[2]Birth Forward, Non-Governmental Organization, Nicosia, Cyprus
[3]Department of Nursing, School of Health Sciences, Cyprus University of Technology, Limassol, Cyprus
[4]Department of Midwifery, University of West Attica, Athens, Cyprus
Contact: kolokotroni.o@unic.ac.cy

Background:

Information-seeking on the internet is very prevalent, in contrast to low attendance of antenatal classes. In addition to varying quality, few digital resources are developed using participatory research approaches.

Methods:

Antenatal learning needs were explored in a modified Delphi survey among the professional community and parents-to-be/new parents. A list of 174 topics was developed using the Nominal Group Technique among antenatal educators and representatives of local professional associations. In an online survey, the relative importance of each was rated on a 5-point scale by the wider professional community and general public. Topics rated by $\geq 80\%$ as at least ''very important'' or by $\geq 50\%$ as ''essential'' by either group were shortlisted and re-rated by delegates of the annual Midwifery conference.

Analysis:

193 health professionals (77.7% midwives) and 275 mothers-to-be/new mothers (56.4% attendance of antenatal classes) participated in the online survey. Based on pre-set criteria, 95 topics (54.6%) were identified, 55 (31.6%) nominated by both groups. Among 18 themes, those with the highest number of nominated topics were: Breastfeeding, Prematurity, Giving birth, Caring for Baby and Mental health & well-being. There was good agreement between the two groups (r = 0.88) and in the top 20 single topics, thirteen were common. Priorities were largely unchanged in the last round, but a number of new topics emerged, including pre-eclampsia and domestic abuse. On a 1-10 scale, health literary of expectant parent was rated at M = 5.7 (SD 1.5) by professionals.

Conclusions:

In a ''changing landscape'' of antenatal education, new technologies provide opportunities for broader reach. This formative research study explored the perceived learning needs and local priorities in order to shape the content of Baby Buddy, a public health digital intervention to enhance the health literacy of new parents and support the educational role of health professionals.

Key messages:

- Local needs and priorities for a digital parenthood platform were identified using a Delphi method.
- Participatory formative research can maximize the potential though co-creation and co-ownership.

Smoking and substance abuse prevalence in adolescents in a city of Turkey

Erkan Pehlivan

B Mete[1], E Pehlivan[2], V Söyiler[1]
[1]Provincial Health Directorate, Department of Public Health, Bingöl, Turkey
[2]Inonu University, School of Medicine, Battalgazi, Malatya, Turkey
Contact: erkan.pehlivan@inonu.edu.tr

Background:

The aim of this study was to determine the prevalence of smoking and abuse of substance among young people aged 14-18 in a city of Turkey and to determine the relationship between smoking and substance abuse risk.

Methods:

This cross-sectional study was conducted on high school students studying in Bingöl city center. The universe of the study consists of 14000 students studying in 14 high schools. The minimum sample size required to be reached in the sample size analysis with reference to 80% power and 99% confidence interval was found to be 1235. According to the stratified sampling method, the students were randomly reached in schools and questionnaires were conducted under supervision by taking their consent. Chi-square test, Binary Logistic Regression test were used for data analysis.

Results:

The mean age of the students was 15.71 ± 1.16 (min-max: 14-18) and 49.5% were male. The prevalence of smoking among all students is 15.8%, addictive substance use / trial frequency 5% except smoking. The prevalence of smoking among male students is 24.1%, in female students 7.7%. The rate of using addictive substance was found to be 8.2% for male students and 1.9% for female students except smoking. According to the results of Logistic Regression; substance abuse increases 8 (95% CI:3,32-19,95) fold in smokers (p = 0,001) and 2.5 (95% CI:1,10-5,38) fold in men (p = 0,027). The risk of substance use increases 1.05 (95% CI:1,02-1,08) fold as the number of cigarettes smoked daily (p = 0,001). Substance abuse risk of 18-year-olds shows increase 1.5 (95% CI:1,06-1,93) fold according to 14 years old (p = 0,021).

Conclusions:

Smoking and addictive substance use in adolescents are particularly remarkable in male students (8.2%). This result is higher than the data reflecting Ä°stanbul (7%). This may be due to the fact that the province is located at the crossing point of drug traffic. Smoking increases the risk of other addictive substances (marijuana, heroin, etc.).

Key messages:

- Smoking and substance abuse is an important health problem in adolescents according to this study.
- Male students smoke are at risk of substance abuse more than female.

The effect of Women's decision-making autonomy on family Planning acces in Senegal in 2017

Ndeye Mareme Sougou

NM Sougou[1,2], O Bassoum[1,2], MMMM Leye[1,2], A Tal-Dia[1,2]
[1]Department of Preventive Medicine and Public Health, Faculty of Medicine, University Cheikh Anta Diop, Dakar, Senegal
[2]Institute of Health Development, Faculty of Medicine, University Cheikh Anta Diop, Dakar, Senegal
Contact: nmsougou@hotmail.com

Background:

The impact of access to decision-making on women's health in the choice of fertility control has been highlighted by research. The aim of this study was to analyze the impact of access to decision-making for women's health on access to family planning in Senegal in 2017.

Methods:

The analyses of this study had been done on the Individual Records file of Senegal's Demographic Health Survey 2017. This data covered 8865 women aged 15 to 49 years. The propensity scores matching method had been done. The variable access to the decision was considered as the variable of interest. Matching was done using variables that were not modified by the effect of the treatment. These were religion and socio-economic level. The outcome variables were modern contraceptive use, the existence of unmet needs and the type of modern contraceptive method used. Significance was at 5%. The condition of common support had been respected. The analysis was done with the STATA.15 software.

Results:

Six percent (6.26%) of women could decide about their health on their own. Access to decision-making increased significantly with the woman's age ($p < 0.05$). Fifteen percent (15.24%) women used a modern contraceptive method. Women using a contraceptive method were more numerous in the group with access to decision-making (29.43%) with a significant difference with the other group of 8% ($p < 0.05$). After matching, there was no significant difference between women in terms of modern contraceptive use and the existence of unmet needs. There was a significant difference in the type of contraceptive method used between the two groups of women. These differences were 23.17% for Intra Uterine Device, 52.98% for injections, 08.9% for implants and 10.79% for condoms.

Conclusions:

Access to decision-making for health would facilitate women's access to long-acting contraceptive methods. These findings show the importance of implementing gender transformative interventions in improving access to family planning.

Key messages:

- Access to decision-making for health would allow better access to modern contraceptive methods, especially those with a long duration of action.
- Better consideration of gender disparity reduction could improve access to family planning in Senegal.

Association of maternal developmental disorder traits with child maltreatment

Takeo Fujiwara

T Fujiwara[1]
[1]Department of Global Health Promotion, Tokyo Medical and Dental University, Tokyo, Japan
Contact: fujiwara.hlth@tmd.ac.jp

Objective:

Maternal mental disorders are known risk factors for child mistreatment. However, little is known about the involvement of maternal developmental disorder traits. The aim of this study was to examine maternal traits related to Pervasive Developmental Disorder (PDD) and Attention Deficit Hyperactivity Disorder (ADHD), and their possible association with child maltreatment.

Methods:

Maternal PDD and ADHD were assessed through a self-administered questionnaire (N = 846) during mid-pregnancy using the Pervasive Developmental Disorders Autism Society Japan Rating Scale (PARS) and Adult ADHD Self-Report Scale (ASRS). The mothers completed another questionnaire on child mistreatment when the offspring was approximately 18 months of age. The associations between maternal PDD and ADHD traits and child maltreatment score were analyzed using linear regression models adjusted for covariates.

Results:

Mothers who exhibited stronger PDD traits showed significantly higher child maltreatment score, even after adjustment for maternal characteristics at baseline and ADHD traits. At the same time, ADHD traits were significantly associated with child maltreatment after adjustment of covariates, although the association became non-significant after adjustment of PDD traits.

Conclusions:

Mothers who showed PDD and ADHD traits during pregnancy were more likely to maltreat their children. It is essential to educate mothers with such traits with appropriate, easy-to-follow childcare instructions, preferably in simple language combined with pictorial aids.

Key messages:

- Maternal developmental disorder traits are risk factor of child maltreatment.
- Specific parenting training intervention for mothers with developmental disorders are needed.

Maternal health care for refugee women in Germany: A qualitative approach on the interaction level

Anne Kasper

A Kasper[1]
[1]Department of Prevention and Health Promotion, Bielefeld University, Bielefeld, Germany
Contact: Anne.kasper@uni-bielefeld.de

Background:

In the recent past, the number of forcibly displaced people increased worldwide. About 1/3 of the persons seeking asylum in Germany are female. The majority of all refugee women who are coming to Germany are currently of childbearing age. Refugee women are considered a highly vulnerable refugee subgroup, as they frequently experience physical strains and psychological burdens while fleeing their home countries and being pregnant at the same time. Moreover, pregnancy and the following period require specialized care and support in order to allow a transition to maternity without complications. The aim of this project is to analyze maternal health care services for refugee women on the level of interaction with maternal health care professionals in Germany.

Methods:

Maternal health care professionals in outpatient and clinical settings with experiences of caring for refugee women were recruited. Semi-structured interviews were conducted. The interviews are currently analyzed following the standards of qualitative thematic analysis.

Results:

Maternal health care professionals experience challenges in executing particular maternal health care actions, such as taking the medical history where there is no communication possible or performing examinations where there is no or little privacy (e.g. in camps). In addition there are changes in tasks, which are no subject to originally maternal health care, such as organizing translation and transportation. Furthermore they face a shortage of resources (e.g. translators, time), which constrains them to find solutions on an individual level.

Conclusions:

Maternal health care professionals provide maternal health care to refugee women under special circumstances (e.g. communication barriers, discontinuity of care). As there are limited resources (e.g. translators, time) they develop solutions and strategies on an individual level.

Key messages:

- Challenges and opportunities are disclosed by examining maternal health care professionals' actions.
- Maternal health care improves through understanding maternal health care professionals' strategies.

''Shared learning in action'' - model of early prevention program on drug abuse in primary schools

Anđelka Grujičić

A Grujičić[1]*, S Mladenović Janković*[1]*, D Matijević*[1]*, N Kovačević*[1]*, N Stefanović*[1]
[1]Health Promotion Center, Institute of Public Health of Belgrade, Belgrade, Serbia
Contact: andjelka.grujicic@zdravlje.org.rs

Issue/Problem:

In Serbia, 12,8% of younger adults and 16,5% of sixteen years old adolescents have tried some of the illegal drugs. ''Creative workshop with schoolchildren on prevention of drug abuse'' program was developed as a part of National strategy against drug abuse, aiming to improve capacities of teachers and children in primary schools.

Description of the practice:

Program based on educational approach ''Shared learning in action'' changes traditional school roles, transforming teachers into facilitators, allowing full expression of children's ideas, thus enhancing development of their emotional intelligence. Children's research about drugs mobilizes an extensive list of supporters in gathering relevant information: health workers, police, psychologists, teachers, parents and media. This information is then shaped into a variety of products with strong public health messages: songs, posters, comics, brochures, short plays and videos.

Results:

Since 2010, around 450 teachers and nearly 7000 children in 115 Belgrade primary schools were included. Children's knowledge about drugs has an upturn of over 50%, concurrently with improvement of their teamwork skills, self-confidence, research and creative potentials. Both teachers' and children's evaluation grades show a high level of satisfaction with the program.

Lessons:

This program is an example of cooperation between educational and health sector, followed by a well implemented monitoring system and quality improvement. Its universal and flexible approach made it a part of official curricula in several schools. It was acknowledged as good practice by the Institute for improvement of education in 2012 and The City of Belgrade in 2018. Since 2014, the program has its Facebook page ''Tvoje znanje menja sve''.

Key messages:

- High grade of children autonomy, supported by teachers and community, makes the learning process amusing and effective.
- Program achievements demonstrate its potential for systemic implementation to a wide range of public health topics.

Prevalance of Using Cigarette,Alcohol,Substance Among High School Students and Factors Affected Them

Ali Ozer

Y Levent[2]*, A Ozer*[1]*, A Gokce*[3]
[1]Public Health, Inonu University, Medical Faculty, Departmen of Public Health, Malatya, Turkey
[2]Siirt Central District Health Directorate, Siirt, Turkey
[3]Public Health, Inonu University, Medical Faculty, Malatya, Turkey
Contact: aliozer91@hotmail.com

Background:

Usage rate of cigarette, alcohol, and substance is increasing day by day.Protectiv efactors have primary importance for prevention of substance use.The aim of this study is to investigate the prevalance of using cigarette, alcohol and substance and research relationship between risk factories and substance using, among high school students.

Methods:

Ä°n Malatya city there are 17866 Anatolian, 14381 Vocational,10362 Religious high school students.Totally all of this 42629 students form the universe of this cross-sectional study. When the prevalance of using cigarette accepted as 25 % in high school students; sample size in Anatolian high school,Occupatioanal high school and Religious high school was found 283, 283 and 280 respectively.This survey was conducted in 9 different high schools which choosed by stratified sampling method, and 975 high school students have been reached in this survey.Ä°n the statistical analysing of data,Chi square test, logistic regression test were used.

Results:

The prevalance of cigarette, alcohol and substance using found 34%, 14.3% and 4.2% respectivey among students participating in the survey.Cigarette using; in male students is 2.2 times higher (Cl 95%,1.661-3.073), in alcohol users is 7.6 times higher(Cl 95%,4.919-11.834)($p < 0.05$).Alcohol using is 9.6 times higher(Cl 95%, 5.712-16.250) in cigarette smokers($p < 0.05$).And alcohol using in students with alcohol use in their families is 26.8 times higher(Cl 95%,12.489-57.711)($p < 0.05$).Substance using; found 12.2 times higher(Cl 95%,4.900-30.566) in alcohol users,2.4 times higher(Cl 95%,5.712-16.250) in cigarette smokers and 5.6 times higher(Cl 95%,1.366-23.068)in students with substance use in their families ($p < 0.05$).

Conclusions:

Cigarette using is more common in males and alcohol users.Alcohol use increses in smokers and students with alcohol use in their families.Substance use among students increases when student uses cigarette or alcohol and if there are substanceuse in their families.

Key messages:

- Alcohol use increses in smokers, smoking increses in alcohol users.
- Substance use increses in smokers, alcohol users and in the students with substance use in their families.

Indications and practices of Cesarean Sections in a French region – The Robson classification

Emeline Laurent

E Laurent[1,2], AI Lecuyer[1,2], S Baron[1,2], C Diguisto[3,4], D Turpin[5], J Potin[3,5], L Grammatico-Guillon[1,4]
[1]Public Health Unit, Teaching Hospital of Tours, Tours, France
[2]Research Team ''Education, Ethique, Santé'' (EA7505), University of Tours, Tours, France
[3]Obstetric Unit – Olympe de Gouges Maternity, Teaching Hospital of Tours, Tours, France
[4]University of Tours, Tours, France
[5]Perinatal Healthcare Network - Centre Val-de-Loire, Perinatal Healthcare Network of the Centre Val-de-Loire Region, Tours, France
Contact: e.laurent@chu-tours.fr

Background:

Cesarian-section (CS) deliveries, although sometimes vital, are associated with increasing immediate- and long-term maternal and/or neonatal risks. The objective was to describe the indications of scheduled CS, measure the potentially avoidable CS and study the rate variations between maternities in one French region, Centre Val-de-Loire (CVL).

Methods:

A cross-sectional study was conducted from September 2016 to February 2017. Information about all CS performed in the maternities of the region was collected: medical history, indication, schedule. Data collection was completed with the 2016 regional birth data repository (25,864 deliveries, including 19.2% of CS, among which 7.0% were scheduled). CS were classified according to the pre-existing risk high or low of CS as defined by the Robson classification.

Results:

During the study period, 1,979 CS (18.6% of deliveries) were performed, of which 762 were scheduled (7.1% of deliveries). The main indications for planning a CS were: scarred uterus (60%, of which 56% with only one previous CS) or breech presentation (25%), considered at high risk of CS according to the Robson classification. For these two contexts, the regional birth repository showed decreasing scheduled CS rates from high to low level of maternities' expertise. Remarkly, 22 nulliparous women with a single cephalic pregnancy in spontaneous labor before term (Robson's low risk of CS) had a CS performed for unfavorable pelvimetry (0.2% of deliveries).

Conclusions:

This study allowed identifying specific potential interventions: targeted CS on scarred uterus with only one previous CS or breech presentation, as recommended by national guidelines, and targeted use of radiologic pelvimetry. The Robson classification must be widely used to assess practices through cautious maternity comparisons to improve quality of care.

Key messages:

- Although potentially avoidable c-sections are rare, interventions were identified: targeted CS on uterus with one previous CS or breech presentation, targeted use of radiologic pelvimetry.
- The Robson classification must be widely used to assess practices, in order to improve healthcare quality.

One-year activity of a ''Casa de Espera'' (Maternity Waiting Home) in the south of Angola

Mattia Fattorini

M Fattorini[1], G Raguzzoni[2], C Cuccaro[1], N Nante[1,3], G Messina[1,3], JMN Ndilimondjo[4], W Ndapandula[5], G Tuitileni[5], C Caresia[6], G Putoto[7]
[1]Post Graduate School of Public Health, Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[2]Post Graduate School of Public Health, University of Bologna, Bologna, Italy
[3]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[4]Hospital Management, Catholic Mission Hospital of Chiulo, Chiulo, Angola
[5]Chiulo Maternity Waiting Home, Doctors with Africa CUAMM, Padua, Italy
[6]Local Health Coordination, Doctors with Africa CUAMM, Padua, Italy
[7]Operational Research Unit, Doctors with Africa CUAMM, Padua, Italy
Contact: fattorini7@student.unisi.it

Background:

Maternity Waiting Homes (MWHs) are structures usually located close to health facilities able to provide emergency obstetric care. Women can decide to be hosted in MWHs and when labour begins they move to the health facility for the delivery. Although the effectiveness of MWHs is debated, literature shows increasing findings about their importance. Aim of the study is to describe a one-year activity of a MWH located in Angola.

Methods:

Since 2000, Italian Non-Governmental Organization (NGO) Doctors with Africa CUAMM supports the activities of the hospital of Chiulo in the district of Ombadja (Cunene province). Among the implemented projects, the NGO supports the local MWH (in Portuguese, ''casa de espera''), providing dedicated staff and food for all the women hosted in the MWH. The MWH team routinely performs antenatal care visits and brief talks regarding maternal health. In case of pregnancy complications, the staff promptly refers women to the nearby hospital. The MHW team is also involved in routine data collection.

Results:

In 2018, 703 women were admitted in the MWH. Three-hundred and forty-two (48.6%) were between 18 and 24 years of age. Four-hundred and eighty-two (68.6%) were invited to join the MWH by personnel of local health facilities, while 160 (22.8%) by family members and 61 (8.7%) by community health workers/traditional birth attendants. Age less than 18, previous abortion and/or caesarean were the most assessed factors for high risk pregnancy. In 2018, 1364 deliveries were performed in the hospital, and 593 (43.5%) concerned women hosted in the MWH.

Conclusions:

To achieve the 2030 Sustainable Development Goals targets regarding maternal and neonatal mortality, the implementation of MHWs could represent an effective tool, especially in countries such as Angola where these indicators show a weak annual reduction. Regarding Chiulo's MWH, an improvement of data collection could lead to a better comprehension of the efficacy of the facility.

Key messages:

- In the SDGs era, countries with a high burden of maternal and neonatal mortality should implement various and integrated approaches to achieve significant reductions of these indicators.
- Although the effectiveness of maternity waiting homes is still debated, increasing findings suggest that they could

represent an effective tool to contain mother and child mortality.

Finding alternative roles for Traditional Birth Attendants: an experience from the south of Angola

Mattia Fattorini

M Fattorini[1], G Raguzzoni[2], C Cuccaro[1], N Nante[1,3], C Quercioli[4], F Ileni[5], MC Kaunawoye[5], C Caresia[6], G Putoto[7]
[1]Post Graduate School of Public Health, Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[2]Post Graduate School of Public Health, University of Bologna, Bologna, Italy
[3]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[4]Hospital Val d'Elsa, Local Health Unit Tuscany South-East, Siena, Italy
[5]Sexual and Maternal Health Section, District Health Department of Ombadja, Xangongo, Angola
[6]Local Health Coordination, Doctors with Africa CUAMM, Padua, Italy
[7]Operational Research Unit, Doctors with Africa CUAMM, Padua, Italy
Contact: fattorini7@student.unisi.it

Background:

Reduction of maternal mortality ratio (MMR), a key indicator contained in the Sustainable Development Goals (SDGs), is strictly related to maternal empowerment and to an increasing access to skilled care in pregnancy, childbirth and postpartum. The WHO recommends to define alternative roles for Traditional Birth Attendants (TBAs) in the transition from birth with TBAs to birth with Skilled Birth Attendants (SBAs), in particular in countries where maternal care services still do not meet recommended standards.

Objectives:

In 2018, the Italian Non-Governmental Organization Doctors with Africa CUAMM and the District Health Department of Ombadja (a 350000 inhabitants district in Cunene province, south of Angola) started a three-year multifaceted project to support and strengthen local health services. Aim of this work is to describe the first six months of an implemented activity involving 120 local TBAs, identified and trained to perform basic educational talks in the district territory regarding topical issues of mother and child health. TBAs were also engaged in the referral of pregnant women to health facilities with SBAs.

Results:

From June to November 2018, TBAs performed 2272 talks about maternal and child health issues: healthy pregnancy (551 talks, 24.3%), nutrition (404, 17.8%) and malaria (370, 16.3%) were the most debated topics. The total of women's presences during these educational talks was 57504, and 15379 of them (26.7%) were pregnant. TBAs referred to health facilities 226 pregnant women for a delivery assisted by SBAs.

Conclusions:

Angolan estimated MMR in 2015 was 477/100000 live births: therefore, more efforts should be made to contribute to the achievement of 2030 SDGs target of 70/100000 globally. Moreover, the country percentage of deliveries assisted by SBAs is less than 50%. Promoting alternative roles for TBAs into the mother and child health framework could represent an effective way to improve maternal and neonatal outcomes.

Key messages:

- According to the World Health Organization, defining alternative roles for traditional birth attendants could represent an effective way to support the health of women and children.
- Traditional Birth Attendants can play an important role in providing basic health education and in the ''referral chain'' of pregnant women to health facilities with skilled birth attendants.

Abortion among French students: result of a 15 years follow-up in a French university

Laurent Gerbaud

L Gerbaud[1,2], C Bourdet[1], B Chabanas[1], A Perrève[1]
[1]Service de Santé Universitaire, Université Clermont Auvergne, Clermont-Ferrand, France
[2]Service de Santé Publique, Université Clermont Auvergne, CHU Clermont-Ferrand, CNRS, SIGMA Clermont, Institut Pascal, Clermont-Ferrand, France
Contact: lgerbaud@chu-clermontferrand.fr

Issue:

The level of abortion in France is judged high, and since 2002 a policy is developed among students to lower it in this particular population

Methods:

Since 2003, every 2 years we made an anonymous survey on abortion frequency, reasons and care in our university, which has between 12.000 and 12.000 she-students. We work on data from abortion centres of our area.

Results:

Abortion rates are stable (5,3-8,5%0), half of the French rate for women (12,0-15,1%0).The risk is significantly lower for French students (6,3%0) compared to students from China (relative risk - RR 1,7, with a significant fall since 2011 - after a specific information campaign on contraception in France), North Africa (RR 2,0 stable) and Sub-Saharan Africa (RR 7,6 stable). ¼ had no contraception, ½ used condoms and 1/3 used oral contraception. 7,2% took emergency contraception. Medical abortion count for 1/3, but ¾ of the surgical techniques could have been replaced by medical drugs. After abortion, condoms are no more used and only 1% of the she-students decided not to take contraception. The main change is the fall down of the use of oral contraception after abortion (from 77% to 43%) replaced by intra-uterine device (IUD- from 1,7% to 22,5%) and contraceptive implant (CI- from 6,4% to 19,6%). Complete qualitative and quantitative results for 2018 will be also presented.

Lessons:

General information on contraception did not change abortion rates, except for Chinese students. But, the increase use of hidden contraception (IUD and CI) after abortion encourage us to insist to the use of these hidden devices for the she-students belonging to social groups where contraception is discredited as a way to promote ''bad habits''.

Key messages:

- Since 2003, abortion rates are stable among french students, and concerned mainly foreign students.
- The greater use 'hidden' devices of contraception may improve this situation.

Direct and the Indirect Determinants of Weight-Control Behaviours among Adolescents

Aviad Tur-Sinai

A Tur-Sinai[1], T Kolobov[2], R Tesler[3], O Baron-Epel[4], K Dvir[5], Y Harel-Fisch[2]
[1]Health Systems Management, The Max Stern Yezreel Valley College, Yezreel Valley, Israel
[2]School of Education, Bar-Ilan University, Ramat Gan, Israel
[3]Health System Management, Ariel University, Ariel, Israel
[4]School of Public Health, University of Haifa, Haifa, Israel
[5]Research, Henrietta Szold Institute, Jerusalem, Israel
Contact: avts2309@netvision.net.il

Background:

Economic determinants such as socioeconomic inequalities and parents' employment have a profound impact on the health of adolescents in terms of unhealthy weight-control behaviours (UWCB). In addition, various family factors may play a role in adolescents' weight-control behaviours (WCB). This study examines the association among socioeconomic status, perceived family wealth, and number of employed parents and Israeli adolescents' WCB and asks whether family variables (parental communication, monitoring, support, and family meals) mediate WCB.

Methods:

Data from the cross-sectional questionnaire of the 2014 Israeli Health Behaviour in School-Aged Children study are analysed using structural equation modelling. The research population includes approximately 7,000 Israeli schoolchildren in grades 6, 8, and 10. The association among socioeconomic status (SES) factors (SES measures, parental employment), socio-demographic factors, and weight-control behaviours among adolescents is calculated.

Results:

High family affluence and high perceived family wealth are negatively associated with unhealthy weight-control behaviour. Having two employed parents leads to lower levels of UWCB. Family-related variables like family communication and support and parental monitoring are found to mitigate unhealthy weight-control behaviours. Family meals have a significantly positive effect on healthy weight-control behaviour and a significantly negative impact on unhealthy weight-control activities.

Conclusions:

The findings suggest that economic factors such as SES and number of employed parents are necessary strategies for long-term weight-control practice. The combination of WCB and family meals is the most effective method for adolescents' healthy weight-control behaviour.

Key messages:

- The study highlights the importance of considering the quality of family communication and support as a health asset that may contribute to WCB among young people.
- Family affluence and perceived family wealth, which were two separate measurements, were perceived differently by adolescents.

Cancer education support project: Spread of cancer education in Japan based on web search

Kayoko Katayama

KK Katayama[1], MS Sakaguchi[1], DI Ishikawa[2]
[1]Cancer Prevention and Control Division, Kanagawa Cancer Center Research Institute, Yokohama-City, Japan
[2]Information Department, Kanagawa Children's Medical Center, Yokohama-City, Japan
Contact: katayama@gancen.asahi.yokohama.jp

Background:

Since 2019, cancer education has been introduced in health classes from junior high school students in Japan. This research contributes to how "cancer education," which is a newly launched cancer countermeasure plan, penetrates the general public.

Methods:

In August 2018, the authors prepared an operation manual for classifying Web search results. A researcher majoring in informatics performed the operations outlined below.

- For the list (top 100 results of a Google search) of the Web search results using "cancer education" as the keyword, the link destinations starting from the top result were viewed in order using the browser.
- The name of the organization, the format of information media, summary of website information, and actions in case of a broken link were documented by the researcher.

Results:

"Ministry of Education, Culture, Sports, Science and Technology Elementary and Secondary Education Bureau" occurred the most frequently at the rate of four times when the source word was "cancer education." When this rate of occurrence was tabulated by the organization, the order was as follows: average companies (21.7%), prefectural (17.4), medical facility (12.0), and educational committee (9.8). In the format of information media, page link was the most common, followed by news articles and PDF files. The business type of the average companies were classified as follows: internet operations (30%), new website management companies (20), mail-order companies (15), and pharmaceutical companies (10).

Conclusions:

Although public facilities and hospitals were more commonly involved in promoting cancer education, the holding of educational seminars by insurance companies and the creation and publication of cancer educational videos by pharmaceutical companies gradually trigger the interest of private companies in cancer education. The possibility of contribution to future development was demonstrated. This work was supported by 14th Hakuho Research Grant.

Key messages:

- In Japan, cancer education was introduced to school education from 2019.
- Private companies are expected to entry into cancer education in the future.

Health related behaviours of secondary students living in dormitory in Hungary

Petra Skerlecz

P Skerlecz[1], B Gulyás[2], L Nedeczky[3], J Takács[4], Zs Rákosy[1]
[1]Department of Public Health Medicine, University of Pécs Medical School, Pécs, Hungary
[2]Federation of Children's and Youth Municipal Councils, Hódmezővásárhely, Hungary
[3]Hope for Children Hungary, Budapest, Hungary
[4]National KID Association, Debrecen, Hungary
Contact: petraskerlecz@gmail.com

Background:

Previous studies have shown that unhealthy eating habits and lack of exercise are still widespread among high school students. Hungary and many other countries have attempted to introduce campaigns and health education programs among adolescents to promote healthier lifestyle, but the effectiveness of these programs is unclear. Our aim was to investigate the consistency between knowledge and behavior in adolescents.

Methods:

A self-administered questionnaire survey was conducted in 9 secondary schools' student dormitories, involving 163 students. Descriptive statistics were estimated and chi2- test was used to compare the prevalence between groups.

Results:

Of the participants 69.3% reported their health status good, girls and those students who studied in vocational school frequently considered their own health bad ($p = 0.002$). Almost all of them highlighted the importance of regular physical activity, but 27.7% had low physical activity. Daily consumption of fruit and vegetables seems to be characteristic just half of the students, the structure of their daily snacks consists more in sugar-sweetened snacks (21.7%) and energy dense beverages (22.8%). Students with higher level of health-consciousness rated better their own health status and took exercise more frequently, but the higher level of health-consciousness had not positive effect on the healthy food consumption ($p = 0.143$).

Conclusions:

Our findings suggest lack of exercise and unhealthy eating habits were still widespread among high school students. The results of the study showed that adolescents have sufficient knowledge about healthy lifestyle, however, it has little impact on their health-related behaviour.

Key messages:

- The most important characteristic of an effective health promotion programme is its ability to change behaviour.
- Health promotion programmes should continue in schools, especially focus on behaviour changing interventions to effectively influence the health of the students.

Teenage mothers: a long-term view on their well-being

Amke van Tintelen

AMG van Tintelen[1], SH Bolt[1], DEMC Jansen[2]
[1]Research Department, Fiom, 's-Hertogenbosch, Netherlands
[2]Department of Sociology, University of Groningen, Groningen, Netherlands
Contact: avtintelen@fiom.nl

Background:

This study aims to address the lack of information about teenage mothers in different stages of their lives by exploring how they are doing in the long term and the social support they receive.

Methods:

From December 2018 to February 2019 teenage mothers in the Netherlands were recruited by Fiom (an expert centre for unintended pregnancy), via social media and a website for teenage mothers (n = 248). Using an online survey, data were obtained to assess various outcomes, such as well-being, education, work, income, housing and social support. Respondents were divided into three groups: 0-3 years after teenage childbearing (short-term), 4-12 years (medium-term), >12 years (long-term). Results were analysed using univariate and bivariate descriptions in SPSS.

Results:

Almost 80% of the respondents reported that they were doing well and were satisfied with their life. 63.3% had a job, and 17.0% was enrolled in education. Short-term mothers worked fewer hours per week compared to long-term mothers ($p < 0.001$). 85.1% of the respondents reported that they received benefits, short-term mothers receiving more benefits than long-term mothers ($p < 0.001$). The majority (78.2%) was satisfied with their living conditions; short-term mothers were less satisfied than long-term mothers ($p = 0.031$). 36.3% of the respondents smoked cigarettes. Most support was given by family (83.1%), mainly from female relatives. About 24% of the respondents received formal support.

Conclusions:

This study shows that teenage mothers, on average, were doing well and were satisfied with their life, in both the short and long term. Regarding income and housing, short-term mothers were in a less favourable position. These results suggest that as the years pass, teenage mothers overcome difficulties. Since the association between well-being and social support on the long term is unknown, we advise investigating the effect of social support on the outcomes of teenage childbearing.

Key messages:

- Both in the short-term and the long-term, most teenage mothers were doing well and satisfied with life.
- Regarding housing and income, short-term mothers function less well compared to long-term mothers.

Caesarean Delivery Rates in Birth Centres: confrontation using Robson Classification

Margherita Napolitani

G Bocci[1], *N Nante*[3,2], *M Napolitani*[2], *I Scinicariello*[4], *L Kundisova*[2], *G Messina*[3,2], *L Alaimo*[3]
[1]Public Hygiene and Nutrition Department, Local Health Unit Tuscany South-East, Siena, Italy
[2]Post Graduate School of Public Health, Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[3]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[4]Degree Course in Obstetrics, University of Siena, Siena, Italy
Contact: napolitani1005@hotmail.it

Background:

A caesarean section (CS) is a life-saving procedure, reducing perinatal mortality and morbidity, over last decades CS rates are increasing. In 2015 the Robson classification (RC) was introduced by WHO as a global standard for assessing, monitoring and comparing CS rates within healthcare facilities and between them. The aim of this cross-sectional study was to identify the most numerous groups according to RC.

Methods:

All women, who delivered by CS from January 2015 to June 2017 in two hospitals in the province of Siena (Italy): I level Birth Centre of Grosseto (GR) and II level Birth Centre of Siena (SI) were included. Age, type of hospital and group based on RC were extracted from Medical Register. The RC divides women into 10 groups based on 5 basic obstetric characteristics (parity, number of foetuses, previous CS, onset of labour, gestational age, foetus presentation). The percentages of the group's contribution to the overall CS rate were calculated and confronted for two birth centres. All analysis was performed with Stata.

Results:

A total of 2115 women was analysed, 50.5% from SI. Average age was 34.3±5.7; significantly higher for SI (34.7±5.6vs33.9±5.8). Most contributing groups were group V: multiparous, singleton, cephalic, term, with previous CS (24.2%), group II: nulliparous, singleton, cephalic, term, induced labour or CS (24%), group I: nulliparous, singleton, cephalic, term, spontaneous labour (11.45%), group VIII: multiple pregnancy (10.7%) and group X: singleton, cephalic, pre-term (10.4%).

Differences for type of birth centre were observed for groups I, II, V and VIII: I and VIII were more numerous in SI, II and V in GR (chi2; $p < 0.05$).

Conclusions:

The most numerous groups were I, II e V, concordant with literature. Reduction of CS rates in group V could be obtained through lowering of primary CS rates and by promotion of Vaginal Birth After CS. Healthcare professionals could help to reduce labour-related anxiety and elective CS rates.

Key messages:

- The most contributing groups to overall caesarean section rates were groups I, II e V, as reported in literature.
- Reduction of CS rates could be obtained through lowering rates of primary CS, but also by promotion of Vaginal Birth After CS.

Cesarean delivery and its social determinants in women of childbearing age: analysis of Benin's DHS

Yolaine Glele Ahanhanzo

A Kpozehouen[1], *Y Glèlè Ahanhanzo*[1], *E Klikpo*[2], *C Azandjeme*[3], *C Metonnou*[3], *V Mongbo*[4], *EM Ouendo*[4]
[1]Epidemiologie et Biostatiques, Institut Régional de Santé Publique, Ouidah, Benin
[2]Santé Mentale, Faculté des Sciences de la Santé, Cotonou, Benin
[3]Promtion de la Santé, Institut Régional de Santé Publique, Ouidah, Benin
[4]Système et Politiques de Santé, Institut Régional de Santé Publique, Ouidah, Benin
Contact: nyglele@yahoo.fr

Background:

Caesarean delivery, usually performed on a medical indication, is intended for maternal or fetal rescue. Accessibility issues justify setting up a so-called model of "free caesarean" in several developing countries, including Benin, in order to reduce social inequalities and contribute to the reduction of maternal and neonatal mortality. The study aimed to identify the determinants associated with caesarean delivery in women aged 15-49 in Benin.

Methods:

This is a secondary analysis of data from Benin's Demographic and Health Survey (DHS) 2017 - 2018. It was limited to mothers aged 15 to 49 who gave birth to at least one child in the 5 years preceding the survey. The socio-demographic characteristics of the mother and the variables related to pregnancy were the independent variables. Association between cesarean delivery and its determinants was assessed by odds ratios and their 95% confidence interval using a logistic regression.

Results:

The percentage of mothers who gave birth by caesarean was 6.84%, 95% CI = [6.07; 7.59]. The average age was 29.37 years, 95% CI = [29.20; 29.55]. The probability of cesarean delivery was higher with women aged 45 years and older (OR = 3.33, 95% CI = [1.85, 6.01]), living in urban areas (OR = 1.41, 95% CI = [1.08 1.84]), from rich or very rich households (OR = 1.98, 95% CI = [1.29, 3.05], OR = 1.87, 95% CI = [1.19, 2.96] respectively) and educated (OR = 1.63 95% CI = [1.19, 2.24] and OR = 1.81, 95% CI = [0.97, 3.39] for the secondary and upper levels respectively).

Conclusions:

This analysis shows that cesarean delivery remains associated with the socio-demographic characteristics of the mother, including the level of economic well-being. The current financing model of cesarean should be evaluated for effectiveness and further interventions need to be implemented to account for other factors of disparity.

Key messages:

- Benin health authorities should improve the geographical accessibility of Cesarean section, especially in rural areas.
- The strategies proposed to improve the financial accessibility of cesarean section do not seem effective, so the Beninese authorities should think about revising them.

Pregnancy warning labels on alcohol packaging: results of an exploratory study

Ana Millot

A Millot[1], *K Gallopel-Morvan*[1]
[1]EA 7348 MOS, Ecole des Hautes Etudes en Santé Publique, Rennes, France
Contact: ana.millot@ehesp.fr

Background:

In 2017, approximately 11% of pregnant women in France consumed alcohol despite its harmful consequences on the fetus (Andler, 2018). Our research aims at exploring the impact of warnings displayed on alcohol packaging: the current pictogram and alternative possible messages that differ regarding content and design will be explored.

Methods:

In-depth interviews were conducted with 20 French women, including women who did not drink alcohol during their pregnancy, women who drank alcohol, women in pregnancy planning and breastfeeding mothers.

Questions were asked about the participants perception of drinking alcohol during pregnancy, alcohol warnings: the current pictogram, new contents (negative and positive) for warnings and new designs (different pictograms combined with or without text). A thematic content analysis was carried out.

Results:

The current pictogram lacks visibility and has no impact on the behaviour of the women.

New suggested contents were on the whole welcomed. It can be noted that some participants felt that specific messages (e.g. intellectual disabilities, facial malformations etc.) were a more effective way of preventing alcohol consumption during pregnancy than general ones. On the contrary, other participants felt that a general message such as 'Zero alcohol during pregnancy', or positive messages such as a cessation service message, was more effective.

The majority of participants believed that pictograms with a better visibility; more eye-catching; vivid images of fetuses, etc., would have a greater impact on alcohol consumption.

Conclusions:

This study highlights the need for changes to pictogram currently used on alcohol packaging in France. Our results show that recent changes proposed by the French government (a slight increase in the size of the current pictogram) will most likely have little effect on preventing alcohol consumption during pregnancy.

Key messages:

- The current pictogram on alcohol bottles in France has little or no effect.
- The French government should implement new warnings both in terms of content and design.

Cosmetics and pregnancy: perception of health risk by health professionals and pregnant women

MP Sauvant-Rochat

M Sauvant-Rochat[1], *NGL Kouamé*[1], *MR Fradet*[2], *C Marie*[1], *L Bernard*[1], *S Maquinghen*[2], *D Lémery*[3], *F Vendittelli*[3]
[1]UMR 6602, Université Clermont-Auvergne, CNRS, SIGMA Clermont, Institut Pascal, Clermont-Ferrand Cedex 1, France
[2]Health Observatory of Auvergne-Rhône-Alpes, Clermont-Ferrand, France
[3]UMR 6602, Université Clermont-Auvergne, CHU Clermont-Ferrand, CNRS, Institut Pascal, Clermont-Ferrand, France
Contact: m-pierre.sauvant-rochat@uca.fr

Contex:

During pregnancy, the International Federation of Gyneco-Obstetrics (FIGO) advocates limiting exposure to chemicals present in everyday products, including cosmetics. However, both pregnant women (PW) and perinatal health professionals (PHP) know still poorly this source of exposure. AIMS: The PERICOS-Quali Study aims to identify the perception of the risk associated with the use of cosmetics during pregnancy by PHP and PW.

Methodology:

A qualitative survey was conducted among PHP and PW in Auvergne (France). The data were collected by semi-structured interviews with the PHP and by focus group with the PW, until saturation of the speeches, by an experienced investigator, with an interview guide. The interviews were recorded, the verbatim was transcribed and subjected to a thematic analysis with the N-VIVO v11 software.

Results:

12 PHP (5 midwives, 2 general practitioners and 5 obstetricians) and 24 PW were interviewed. PHP and PW considered cosmetics as wellness and body-care products. Furthermore PHP noted that during pregnancy women used more often organic products, moisturizers or anti-stretch marks, and reduced the use of perfumes, deodorants. In the absence of recommandations based on Evidence-Based Medecine, PHP and PW considered the risk related to cosmetics as not major. The PHP (especially midwives) reported giving advice to comfort the pregnant women; their positioning was not to prohibit the use of cosmetics during pregnancy. PW did not identify PHP as reliable sources of information about cosmetics.

Conclusions:

PHP are seeking for tools to help them to better advice PW. And PW would like also to have pertinent advices about cosmetics to make a reasoned choice.

Key messages:

- Health education about use of cosmetics during pregnancy is necessary.
- Pregnant women and health professionals don't perceive health risk linked to cosmetics.

Evaluation of the oral health of pregnant women in prenatal consultations in Côte d'Ivoire

Guanga David Meless

GD Meless[1,2], *JC Guinan*[1,2], *AD Sangaré*[1,2], *M Traoré*[2], *AA Amangoua*[2], *V Danho-Da*[1,2], *AS Datté*[2], *M Samba*[1,2], *R Bakayoko-Ly*[1,2]
[1]UFROS, Département de Santé Publique, Université FHB d'Abidjan, Abidjan, Cote d'Ivoire
[2]UFROS, Laboratoire de Santé Publique et Plantes Médicinales, Université FHB d'Abidjan, Abidjan, Cote d'Ivoire
Contact: ead_dm@yahoo.fr

Background:

Despite the proven links between oral health status and adverse pregnancy outcomes, oral examination is not systematically integrated into prenatal examinations in Côte d'Ivoire. In addition, there are no prevention messages specifically targeted at pregnant women. Objective: To assess the oral health of pregnant women in Côte d'Ivoire.

Methods:

A cross-sectional survey was conducted at the Maternal and Child Health Department of the National Public Health Institute in Abidjan. The data collected were: age, education level, marital status, source of income, trimester of pregnancy, gestational age, oral hygiene habits and the fact that they whether or not received oral health information. A clinical examination was conducted to assess oral hygiene (OHIS index), periodontal condition (CPI index), dental condition (DMFT index), as well as the presence of epulis, erosion or dental mobility. Frequencies and counts were calculated for the different variables in the study.

Results:

A total of 207 women were observed. The age range was 15 to 44 years with 14.0% under 19 years old. The majority were in couple (76.8%), multi-gesture (77.3%), and more than half had no education (52.2%) or source of income (56.0%); 50.7% snacked between meals and 33.3% had vomiting. They brushed their teeth at least twice a day (70.0%) and had not changed their oral hygiene habits (77.3%) during this pregnancy. Only 3.4% had information on oral health conditions during pregnancy. The frequency of caries was 75.4%, dental erosions 13.0%, gingivitis 57.0%, periodontitis 6.8% and epulis 3.4%.

Conclusions:

The results suggest the integration of systematic dental consultation into prenatal consultations in order permit the sensitization of these women, screening and management of their oral conditions.

Key messages:

- Oral diseases of pregnant women are a reality without their knowledge in Côte d'Ivoire.
- A systematic dental visit is essential during prenatal consultations in Côte d'Ivoire.

Antenatal care initiation in an ethnically dense socially disadvantaged maternal cohort

Shuby Puthussery

S Puthussery[1], L Li[2], Pc Tseng[1], T Puthusserry[3]
[1]Maternal and Child Health Research Center, University of Bedfordshire, Luton, UK
[2]Great Ormond Street Institute of Child Health, University College London, London, UK
[3]Independent Consultant, Independent, London, UK
Contact: shubythomas@yahoo.com

Background:

Differential utilisation of antenatal care among ethnic minority mothers is a contributor to their increased risk of poor birth outcomes in developed countries. Links between ethnicity, area deprivation and the timing of antenatal care initiation remain poorly understood. This study investigated patterns of antenatal care initiation among an ethnically dense, socially disadvantaged maternal cohort.

Methods:

We conducted a retrospective analysis of routinely collected anonymous data of live singleton births in a maternity unit serving an ethnically diverse population. We applied univariate regression models to examine the association between late antenatal care initiation and various predictor variables in particular ethnicity and area deprivation.

Results:

Gestational week at antenatal initiation was available for 46, 089 births. One fifth (20.9%) of mothers initiated antenatal care after 12 weeks of gestation including 11.9% who had their first antenatal appointment at 13 -20 weeks (moderately late) and 8.9% who had it later than 20 weeks (extremely late). Among all the factors considered, late initiation was most strongly associated with non-White British ethnicity. Black African (34.2%) and Black Caribbean (29.0%) mothers were more than twice as likely to initiate antenatal care after 12 weeks of gestation compared to White British mothers [Odds ratio (OR) = 2.69 and 2.15 respectively). The odds did not increase with increasing area deprivation except for moderately late initiation in the most deprived and second most deprived areas [unadjusted OR = 1.54 and 1.24 respectively].

Conclusions:

Non-White British ethnicity was the key predictor of late antenatal care initiation in our ethnically dense socially disadvantaged maternal cohort. Impact: Programs and policies should take in to account ethnic variations in antenatal care initiation while designing programs and policies to improve birth outcomes in ethnically dense socially disadvantaged areas.

Key messages:

- Non-White British ethnicity was the key predictor of late antenatal care initiation.
- Area deprivation per se appeared to have limited association with late antenatal care initiation.

Sequence of cigarette and e-cigarette initiations and daily smoking in adolescents (HBSC 2018)

Maud Dujeu

M Dujeu[1,2], T Lebacq[1,2], C Pedroni[1,2], V Desnouck[1,2], E Holmberg[1,2], N Moreau[1,2], K Castetbon[1,2]
[1]Service d'Information, Promotion, Education Santé (SIPES), Ecole de Santé Publiqe, Université Libre de Bruxelles, Brussels, Belgium
[2]CR en Epidémiologie, Biostatistique et Recherche Clinique, Ecole de Santé Publiqe, Université Libre de Bruxelles, Brussels, Belgium
Contact: mdujeu@ulb.ac.be

Background:

Electronic cigarette may help adults quit smoking. For adolescents, the concern is whether e-cigarette initiation is a gateway to subsequent smoking. Our objectives were to describe the sequence of conventional cigarette and e-cigarette initiations among adolescents who had already used both products, and to analyse the current smoking behaviour according to the first experienced product.

Methods:

Analyses were based on a two-stage random sample of 9,937 12-20-year-old adolescents included in the French-speaking Belgian 2018 Health Behaviour in School-aged Children cross-sectional survey. Cigarette and e-cigarette initiations and its sequence, current daily smoking and other characteristics were collected through a self-administered questionnaire. Associations, adjusted for demographic data, were estimated using logistic regression and weighted. Sampling design was considered in analyses.

Results:

In 2018, 66.0% of adolescents reported never having tried a cigarette and e-cigarette, 8.1% having experimented cigarettes only, 9.2% e-cigarette only and 16.6% having experimented both. Among adolescents who tried both products, eight out of ten smoked cigarettes before trying the e-cigarette (78.2%). In the whole sample, 6.8% of adolescents were smoking every day. Daily smoking was observed in 19.8% of adolescents who initiated e-cigarette and cigarettes and in 6.4% of those who initiated cigarettes only. Adolescents who first smoked cigarettes were more likely to further smoke daily (aOR: 2.48 [1.69-3.64]) than those who first used e-cigarette. The risk of daily smoking was not different between adolescents who first used e-cigarette compared with those who tried cigarettes only (aOR: 1.23 [0.76-2.00]).

Conclusions:

In French-speaking Belgium, conventional cigarette was the first step in the initiation and continuation of tobacco smoking. These findings help understand smoking patterns among adolescents and will support the development of smoking prevention strategies.

Key messages:

- Our findings suggest that health promotion interventions should remain focused on conventional cigarette.
- Based on a cross-sectional study, they should however be confirmed by prospective studies.

Adolescent health literacy in 3 European cities and its association with smoking and smoking beliefs

Pirjo Lindfors

P Lindfors[1], JM Kinnunen[1], L Paakkari[2], A Rimpelä[1,3], M Richter[4], MAG Kuipers[5], AE Kunst[5]
[1]Faculty of Social Sciences, Health Sciences, Tampere University, Tampere, Finland
[2]Faculty of Sport and Health Sciences, University of Jyväskylä, Jyväskylä, Finland
[3]Department of Adolescent Psychiatry, Tampere University Hospital, Tampere, Finland
[4]Institute of Medical Sociology, Medical Faculty, Martin Luther University Halle-Wittenberg, Halle, Germany
[5]Department of Public Health, University of Amsterdam, Amsterdam, Netherlands
Contact: pirjo.lindfors@tuni.fi

Background:

Beliefs about smoking have been found to be associated with smoking behaviour. Similarly, health literacy (HL) as a competence to make health-related decisions has been identified as an independent factor to explain differences in smoking. However, little is known about adolescents' HL in different countries, and how HL is associated with health behaviour and health-related beliefs. The aim of this study is to describe the levels of HL in three European cities, and how HL is associated with smoking and beliefs about smoking consequences.

Methods:

In 2016 as part of SILNE-R study, 5,088 adolescents aged 14 to 16 years answered a school survey in Amersfoort (NL), Hanover (GE) and Tampere (FI). Health Literacy for School-aged Children (HLSAC) covering five components (theoretical knowledge, practical knowledge, critical thinking, self-awareness and citizenship) was used. Questions on smoking and five statements on beliefs about smoking consequences were asked. The analyses were conducted with multinomial logistic regression, and with generalised linear mixed models.

Results:

HL was the highest in Tampere (Finland), then in Amersfoort (the Netherlands), and the lowest in Hanover (Germany). HL was not associated with smoking, but it was positively associated with beliefs about smoking consequences, overall and when stratified by city.

Conclusions:

Health literacy level was the highest in Tampere (FI), which may be due to Health Education as a curriculum-based school subject. In other cities, the education on health is not offered so systematically. Highly health literate students also know more about smoking consequences, but it does not affect their smoking behaviour. Systematic and compulsory health education in schools can be recommended in order to enhance adolescents HL.

Key messages:

- Adolescents' high health literacy was associated with more accurate believes on smoking consequences.
- Health literacy was not associated with smoking behavior.

Socio-demographic and lifestyle determinants of the micronutrients status during pregnancy

Kinga Polanska

K Polanska[1], *E Trafalska*[2], *W Hanke*[1], *E Wesolowska*[1], *A Jankowska*[1], *P Kaluzny*[1], *B Janasik*[3], *J Gromadzinska*[3], *W Wasowicz*[3], *G Calamandrei*[4]

[3]3Department of Biological and Environmental Monitoring, Nofer Institute of Occupational Medicine, Łódź, Poland
[4]Centre for Behavioral Sciences and Mental Health, National Institute of Health, Łódź, Poland
Contact: kinga.polanska@imp.lodz.pl

Micronutrients status during pregnancy is recognized as one of the environmental factors that can have an impact on maternal and children's health. The study aims at evaluating socio-demographic, lifestyle, environmental, and pregnancy-related determinants of maternal micronutrients status during pregnancy.

The analysis was based on data from the Polish Mother and Child Cohort (REPRO_PL). During the second trimester of pregnancy, 1306 women filled in a modified version of the validated food frequency questionnaire (FFQ) based on which the intake of the following micronutrients was estimated: calcium, magnesium, zinc, copper, selenium, folate, vitamin D, vitamin A and vitamin E. In addition, copper, zinc and selenium levels were measured in the blood collected during the second trimester of pregnancy.

About 95% of the women took dietary supplements during pregnancy. Despite such supplementation in the case of a high proportion of the women the intake of majority of the analyzed micronutrients was below recommendations for the pregnancy period (based on the Estimated Average Requirement). The mean plasma zinc, copper and selenium concentrations were 0.9 ± 0.3 mg/l, 2.0 ± 0.6 mg/l and 48.4 ± 10.5 ug/l, respectively. The chance to reach the recommended intake for vitamin A, vitamin D and selenium was higher among the multiparous women ($OR = 1.53$ $p = 0.007$; $OR = 1.44$ $p = 0.02$; $OR = 1.48$ $p = 0.009$) and for zinc among the women with a higher socio-economic status (SES) ($OR = 1.43$ $p = 0.04$). For other variables the results were not statistically significant. A higher selenium level in the plasma was observed among the older women ($p = 0.01$) and those with a higher SES ($p = 0.03$).

The current study presents evidence on specific factors influencing the micronutrients intake. They need to be accounted for in educational programs and interventions that focus on healthy diet recommendations during pregnancy.

Key messages:

- In the case of a high proportion of the women the intake of majority of the analyzed micronutrients was below recommendations for the pregnancy period.
- More effort should be taken to educational programs and interventions that focus on healthy diet recommendations during pregnancy.

Participatory research in the field of early childhood interventions - how can this be achieved?

Marion Weigl

M Weigl[1], *C Marbler*[1], *S Haas*[1], *W Laskowski*[2]
[1]Austrian Public Health Institute (Gesundheit Oesterreich GmbH), Vienna, Austria
[2]Upper Austrian Health Insurance, Linz, Austria
Contact: marion.weigl@goeg.at

The Austrian early childhood interventions programme (‘‘Frühe Hilfen’’) is an overall concept of health promotion measures, aiming to support families depending on their individual needs to create good conditions for raising their children. This should contribute to long-term health of the children. The manifold effects of this complex intervention on the families are to be investigated in the future. To do so, a research concept shall be developed using a participatory research approach. A selective literature search was carried out to identify concrete recommendations for participatory research and previous experiences on the participation of parents. Based on these results, semi-structured interviews and group discussions with families were carried out. According to literature, parents have rarely been used as co-researchers. Our experiences show that access to families in burdened life circumstances is possible via the low-threshold structures of our early childhood interventions programme. In 2018, 21 families participated in interviews and group discussions. The latter method is particularly well suited for obtaining targeted information from families and building trust for long-term cooperation. Still, the stressful family situations make it difficult to participate in research activities. Therefore, specific conditions are required. At present, it is clear that it is feasible to involve families and test research methods together. The next step, an equal cooperation of families and researchers, shall be achieved by the use of a research group. A small group started in Spring 2019, eventually being involved in the implementation of some methods during fall 2019. Whether families are willing to participate continuously for a long time in research activities remains unclear, so far.

Key messages:

- Participatory research with families in stressful situations needs time and patience as well as specific conditions, but it is possible.
- Participation of the target group in the planning phase of further research can lead to relevant insights for programme improvements.

The role of health literacy in explaining regional health differences among adolescents

Nina Simonsen

N Simonsen[1,2], N Wackström[1], E Roos[1,2,3], S Suominen[4,5], R Välimaa[6], J Tynjälä[6], L Paakkari[6]
[1]Public Health Research Program, Folkhälsan Research Center, Public Health Research Program, Helsinki, Finland
[2]Department of Public Health, University of Helsinki, Helsinki, Finland
[3]Department of Food and Nutrition, University of Helsinki, Helsinki, Finland
[4]Department of Public Health, University of Turku, Turku, Finland
[5]Department of Public Health, University of Skövde, Skövde, Sweden
[6]The Faculty of Sport and Health Sciences, University of Jyväskylä, Jyväskylä, Finland
Contact: nina.simonsen-rehn@helsinki.fi

Background:

Health disparities in adolescence track forward to adulthood. In understanding disparities better, health literacy (HL) - as a broad range of health-related competencies - has been identified as a valuable construct. Higher HL has been associated with better health outcomes, also among adolescents. Not much is known about how language or region in a bilingual country is associated with HL, or how HL is associated with regional health disparities. The aim of this study, in a bilingual country, was a) to examine and compare HL and health levels among majority and minority language speaking adolescents in different regions of Finland, and b) to explore if HL explains possible regional health differences in these two language groups, taking into account other important structural stratifying factors.

Methods:

The data of 13- and 15-year-olds were obtained from the Health Behaviour in School-aged Children study, conducted in Finnish- and Swedish-speaking schools in Finland in 2014 (N = 3853/1123; 85/83%). HL was measured with the HLSAC-instrument. The data were analysed by logistic regression and interaction analyses.

Results:

In the total sample, 23% rated their health as excellent; 33% had a high and 10% a low HL. The preliminary findings showed no differences in health or HL between the language groups. However, regional health differences were found in both language groups: in the Finnish-speaking sample among boys, and in the Swedish-speaking sample among girls. Findings also showed regional differences in HL levels in both language groups, especially among the Swedish-speaking minority group. Comprehensive HL was an independent factor in explaining these regional health differences.

Conclusions:

This study adds to prior studies on the role of HL as a modifiable health resource by showing that in addition to other structural stratifying factors comprehensive HL explains regional health disparities among adolescents in a bilingual country.

Key messages:

- This study in a bilingual country found regional health disparities and regional differences in HL levels among both majority and minority language speaking adolescents.
- In both language groups, taking into account other important structural stratifying factors, comprehensive HL was an independent factor in explaining the regional health differences.

Adolescents' use of an online question-answer service to gain health knowledge

Eva Lassemo

E Lassemo[1], K Sand[1]
[1]SINTEF, Trondheim, Norway
Contact: eva.lassemo@sintef.no

Background:

Adolescents prefer to collect information online. However, research has also shown than adolescents lack competency in googling information. Furthermore, boys are less likely than girls to seek help and to discuss their problems. Hence, an online information and question-answer (QA) service staffed by professionals, like ung.no, may provide what adolescents desire. The ung.no QA service is open to ages 13-20, and all questions and answers are publicly available in a searchable database.

The aim of the present study is to investigate who the users of the ung.no QA-service are and what their main concerns are.

Methods:

Data consisted of all questions posted to ung.no 2016-2018. Descriptive analyses were performed using categorization of questions established by ung.no.

Results:

The data consisted of N = 128 289 questions. Overall 68.5% of questions were posted by girls ($p < 0.01$). The gender option 'other' was chosen by 1.7%. Younger adolescents aged 13-16 posted 66.1% of the questions ($p < 0.01$). The age imbalance was most pronounced among girls. The age distribution suggests that users <13 and >20 present themselves as 13- and 20-year olds respectively. Three categories contained 80% of questions, these concerned: body and health (48.1%); school and education; and friends and love. While 52.4% of girls' questions concerned body and health, boys' questions were more evenly distributed among categories. Boys had, relatively, more questions regarding laws and rights, intoxicating substances and school, education and work.

Conclusions:

Analyses reveal that 7 out of 10 users of the ung.no QA service are girls, and that the main area of concern is body and health. Results indicate a need for this QA service for wider age-range. The outreach of the ung.no QA service is universal, and hence has great potential public health impact. The results call for action identifying ways to reach boys and in turn efface gender inequality in help seeking behaviour and improve public health.

Key messages:

- Seven out of 10 users of a public digital QA service for adolescents ages 13-20 are girls, and seven out of 10 are in the youngest age group 13-16.
- The main areas of concern posted to a public digital QA service are regarding body and health, and school and education.

Abriendo Futuros: An empowerment program for indigenous adolescent girls in Yucatán, Mexico

Silvana Larrea

F Romero[1], L Cicolella[1], S Larrea[1], D Domínguez[1], A Aponte[2], A Del Valle[2], K Hallman[3], I Vieitez[1]
[1]PGY, The Population Council, Mexico City, Mexico
[2]PGY, The Population Council, Guatemala City, Guatemala
[3]PGY, The Population Council, New York City, USA
Contact: chivislarrea@gmail.com

Background:

Abriendo Futuros is a a girl-centered empowerment program that engages community leaders and trains older indigenous girls as mentors to run community girls' clubs, known as safe spaces. Mentors work directly with indigenous girls to deliver program curricula tailored to the girls' specific and unique needs to builds girls' assets in areas such as sexual and reproductive education, gender equality, violence prevention, leadership, financial education and healthy lifestyles.

Objectives:

The program aims to improve critical health, social, and cognitive skills that help girls have a voice and choice in their lives and allows them to draw the path to a healthy adult life, overcoming the risks present in their context. The program was implemented in 8 rural communities in the south of Yucatan. A total of 657 girls were enrolled over the 18-month-implementation period (2015 - 2017).

Results:

A quasi-experimental evaluation was implemented in 11 communities (8 intervention and three control). Preliminary findings, using the Propensity Score Matching technique, suggest significant positive effects on intermediate outcomes such as financial literacy, attitudes towards gender norms, sexual reproductive health knowledge, social capital, and perceived exposure to physical violence. No statistically significant results were achieved in main outcomes (reduce adolescent pregnancy and school dropout). We associate this, mainly to the fact that the intervention was only at an individual level, but also to the limited sample size and the brief observation period (18 months).

Conclusions:

Girl-centered programming increases access to spaces where girls meet to expand their knowledge and social networks and build assets that reduce their risks and broadens their opportunities. However, further evidence is needed on multi-level and multisector girl-centered interventions to address teenage pregnancy and other complex issues.

Key messages:

- The program generates a social safety net among girls and mentors that is key to the well-being of girls.
- Girl-centered programs have positive effects on girĺs empowerment for girls who live in vulnerable situations and unequal social contexts.

Barriers and enablers for practicing kangaroo mother care (KMC) in rural Sindh, Pakistan

Mohammad Shah

M Shah[1], Q Jamali[2], F Aisha[2], F Shahid[3]
[1]Global Health, Save the Children US, Lutherville, USA
[2]Health and Nutrition, Save the Children, Karachi, Pakistan
[3]Health and Nutrition, JHPEIGO, Karachi, Pakistan
Contact: mshah@savechildren.org

Background:

More than 2.5 million newborns die each year, contributing to 47% of under 5 mortality worldwide. Globally, Every Newborn Action Plan has emphasized on Kangaroo Mother Care (KMC) as an essential component of neonatal health initiatives. An international joint policy statement and endorsement from health professional associations also recommended practicing KMC for newborn care.

Methods:

We conducted a qualitative study with 12 in-depth interviews (IDIs) and 14 focus group discussion (FGD) sessions, in two health facilities of Sindh, Pakistan during October-December 2016, to understand the key barriers and enablers to a mother's ability to practice KMC and the feasibility of implementing and improving these practices.

Results:

Our study findings revealed that community stakeholders were generally aware of health issues especially related to maternal and neonatal health. Both the health care providers and managers were supportive of implementing KMC in their respective health facilities as well as for continuous use of KMC at household level. In order to initiate KMC at facility level, study respondents emphasized on strengthening of availability and quality of services as well as training of health providers as critical prerequisites. Also in order to continue practicing KMC at household level, engaging the community and establishing functional referral linkage between community and facilities were focused issues in facility and community level FGDs and IDIs. The study participants considered it feasible to initiate KMC practice at health facility and to continue practicing at home after returning from facility.

Conclusions:

Ensuring facility readiness to initiate KMC, improving capacity of health providers, coupled with strengthened community mobilization, and targeting specific audiences may help policy makers and program planners to initiate KMC practice at health facility and keep KMC practice continued at household level.

Key messages:

- Introducing KMC at health facility followed by continuing practice at household level is feasible, even in a religiously conservative setting like Pakistan.
- Facility readiness, improved health workers' capacity coupled with strengthened community mobilization targeting specific audiences could help scaling up this public health intervention in Pakistan.

How adolescents use an online question-answer (QA) service to address their mental issues

Kari Sand

K Sand[1], G Tøndel[2], E Lassemo[1]
[1]SINTEF, SINTEF Digital, Trondheim, Norway
[2]NTNU Samfunnsforskning (NTNU Social Research), Diversity and Inclusion, Trondheim, Norway
Contact: kari.sand@sintef.no

Background:

Ung.no is Norway's largest information website directed at adolescents, with more than 800 000 users per month. Ung.no offers an online QA service in which 13-20-year-olds post their questions and get answers from professionals. Anonymous answers are publicly available online. Descriptive analysis of over 125 000 questions written to ung.no from 2016-2018 showed that most adolescents asked questions about body and health. Subsequent qualitative content analyses of the body-and-health-questions showed that mental health is one of the most prominent topics in the adolescents' questions. The aim of the present study is to investigate how adolescents use the QA service to address mental issues.

Methods:

A random selection of 360 questions - stratified by age and gender - concerning body and health were made. The questions were analysed by use of a qualitative thematic analysis with a functional textual approach, i.e. examining the questions' linguistic functions.

Results:

In the sample, 20 % of the questions concerned mental issues, ranging from negative feelings of sadness, fear or anger, to disorders such as psychosis and depression and grave issues such as suicidal thoughts and self-harm. Three main functions of the adolescents' questions were identified: 1) Telling about their troubles for the first time; some of them did not ask a question in their post, they just described their feelings; 2) Asking what to do when nothing else has been of help and 3) Seeking confirmation of information they have already received from health experts, teachers, parents or friends, or read on the internet.

Conclusions:

A low threshold service such as an anonymous QA service seems to be useful for adolescents when they need and want to tell about their mental issues or seek help, often for the first time. The outreach of the ung.no QA service is universal, and hence has great potential public health impact.

Key messages:

- Adolescents use a low threshold online QA service to address a wide range of mental problems.
- Adolescents use a low threshold online QA service to tell about their mental issues for the first time.

The role of maternal psychological control and pressure on body image in a child's drive for thinness

Lucia Hricova

L Hricova[1], M Bacikova-Sleskova[1], J Benka[1], O Orosova[1]
[1]Department of Educational Psychology & Health Psychology, Faculty of Arts, P. J. Safarik University in Košice, Kosice, Slovakia
Contact: lhricova88@gmail.com

Background:

The drive for thinness (DFT), an indicator of disordered eating, is strongly predicted by body dissatisfaction (BD). In early adolescence, there are other predictors of DFT which rise from the mother-child relationship such as maternal psychological control (PC) and the motheŕs pressure on the child's body image (MP). The explanation of DFT by the child's self-perception of BD and PC as well as the mother's perception of

MP among early-adolescent boys and girls has great importance for public health and is therefore the aim of this study.

Methods:

The research sample consisted of 191 Slovak adolescents (53.4% of girls, Mage = 12.54, SD = 0.58) who completed the Children's Body Image Scale, DFT subscale of Eating Disorders Inventory, Psychological Control Scale-Youth Self-Report; and their mothers (Mage = 40.45, SD = 4.71) who completed the Parental Influence Subscale. Structural equation modelling was performed.

Results:

A hypothesized model was tested to explain DFT by PC and BD, associated with four sources of MP. The tested model did not fit the data well enough. A modified model, where three insignificant sources of MP were excluded, fitted the data well (SRMR = .06, CFI = .95, RMSEA = .04, PCLOSE = .74) and explained 22% of the variance in DFT. The model was statistically equivalent for both genders. DFT was associated with BD ($\beta = .42$; <.001), PC ($\beta = .2$; <.05) and indirectly with the source of MP - child's body image preoccupation (CBI) ($\beta = .15$; <.05), through BD. CBI was associated with BD ($\beta = .27$; <.05).

Conclusions:

The results point to the importance of BD, PC and CBI - a factor reflecting mothers direct pressure on the child's body image, in explaining DFT among early adolescent boys and girls. Other sources of MP (reflecting the mothers concern about her own body image) were not significant in this context. BD and disordered eating prevention strategies for adolescents indicate a respectful mother-child relationship, avoiding pressure and control.

Key messages:

- A mothers direct pressure on child's body image, psychological control and body dissatisfaction are significant in explaining the drive for thinness among early adolescents.
- Body dissatisfaction and disordered eating prevention strategies for adolescents indicate a respectful mother–child relationship, avoiding pushing a child to think, feel, or act as the mother wants.

Employment and health of working parents: a joint effort to uncover hidden treasures in birth cohorts

Ute Bültmann

M Albin[1], U Bültmann[1], M Casas[1], DA Lawlor[1], V Lendzhova[1], R Leombruni[1], C Lissaker[1], R Lucas[1], M Maule[1], S Peters[1], K Polańska[1], J Sarac[1], J Selander[1], H Skroder[1], IS Mehlum[1], M Ubalde-Lopez[1]
[1]OMEGA-NET, Network on the Coordination and Harmonisation of European Occupational Cohorts (OMEGA-NET) project; Task Group 3.3 Employment patterns in the young
Contact: u.bultmann@umcg.nl

Birth and child cohorts include a wealth of valuable and under-utilized data on employment and health of parents during pregnancy, at birth and often at one or more follow-up assessments.

OMEGA-NET is a EU COST Action aimed at creating a network to optimize the use of European occupational, industrial and population cohorts and to promote health research on occupation and employment. Within this network, Task Group 3.3 is exploring the possibility of exploiting birth cohort data to investigate the interplay between health, socio-economic conditions, working life and work participation of parents around and after the birth of their children, identify gaps in knowledge, and devise strategies to fill them.

Using a web-based database, www.birthcohorts.net, we have identified cohorts with occupational and health information in up to 200,000 parents. Out of 47 cohorts with information on mothers, maternal employment status and occupational exposures during pregnancy were recorded in 18 and 35 cohorts, respectively. For paternal exposures, the corresponding numbers were 6 and 15. To exploit these data, many challenges have to be overcome, primarily harmonization of exposures and outcomes. Cohorts cover different time periods and geographical regions, which can be at the same time a challenge and a blessing, providing hints on causal effects and mechanisms. Other strengths of pooling birth cohorts include the life-course nature of data and the possibility to investigate neglected occupationally-related exposures like work-family conflicts and their effects on health.

We argue that parental data collected in birth cohorts are a valuable under-exploited source of information that would allow cross-national comparisons of the relationships between work, career trajectories and health of young parents.

Key messages:

- Birth cohorts hide a treasure of occupational and health information of young working parents.
- OMEGA-NET has plans to dig them out to investigate their interplay.

How early childhood services address health inequalities and child wellbeing in France

Marie-Renée Guevel

MR Guével[1], P Cury[2], F Bissège[1], J Pironom[2], A Dollet[2], F Quidu[1], M Porcherie[1], C Gasquet-Blanchard[3], C Simar[2], The Récits project[1,2]
[1]University Rennes, EHESP Arènes UMR 6051, Rennes, France
[2]Université Clermont Auvergne, ACTé EA 4281, Clermont-Ferrand, France
[3]University Rennes, EHESP ESO UMR 6590, Rennes, France
Contact: marie-renee.guevel@ehesp.fr

Early childhood (0-6 years old) is a key period when talking about health inequalities (HI) and child wellbeing. Over the past decades, research has shown the importance of early investment. In France, early childhood is a period covered by different public policies and different stakeholders from different sectors, i.e. health, education, childcare facilities, social affairs, recreational activities, etc. Both coverage of 0-6 years and intersectorality, are rarely connected in the literature. Based on Bronfenbrenner ecological approach, the Récits project aims to better understand how issues related to HI and child wellbeing are addressed at a local level within local policies as well as by professionals from the different sectors. It also aims to better understand the relations established by families with those professionals.

Two French départements are studied: Allier (03) and Ille-et-Vilaine (35); both are characterised by social and spatial HI. Within these departments, two local authorities were selected as case studies for in depth analysis: secondary analysis of social and health indicators are carried out and qualitative data are gathered through the collection of institutional documents, observations and interviews with local decision-makers, professionals and families.

First results, focusing on local public policies and how they are implemented by local stakeholders, highlight the diversity of the strategies developed according to the local social context and to the sector. Partnership between the different sectors is valued in policies however the way they work varied, notably, depending on the history of the collaboration.

By clarifying the issues related to the articulation between public policies, local interventions and individual and collective practices of early childhood professionals, this research will contribute to improve and develop strategies to reduce HI and support children and families with respect to their expectations.

Key messages:

- Thanks to its ecological and intersectoral approach, this project will highlight how early childhood services may contribute to tackle health inequalities and to improve child WB.
- Addressing the complexity of the interactions between public policies, professionals and families will lead to a better understanding of the current challenges crossing the field of early childhood.

Maternal characteristics in childhood and smoking at age of 15: Findings from the Czech Republic

Jitka Pikhartova

J Pikhartova[1,2], L Andryskova[2], H Pikhart[1,2]
[1]EPH, UCL, London, UK

[2]RECETOX, Masaryk University, Brno, Czech Republic
Contact: j.pikhartova@ucl.ac.uk

Objective:

Maternal employment has been shown to influence child's health, cognitive and behavioural outcomes. There is only a limited number of studies in Central Europe investigating the impact of parental employment on the uptake of smoking in children. The aim of this work is to look at the influence of maternal employment over the whole period of childhood of their children, and other maternal social and behavioural characteristics on the uptake of smoking among children aged 15 in the Czech part of European Longitudinal Study of Pregnancy and Childhood (ELSPAC).

Methods:

There were 971 individuals with complete data on smoking behaviour at age of 15, pattern of maternal employment between child ages 3 and 15, and other covariates including gender, maternal age, maternal education and marital status, household income, and maternal smoking. Logistic regression was used to analyse the association between maternal employment and smoking in their children.

Results:

37% of adolescents aged 15 years reported trying cigarette more than once. Preliminary results suggest that those whose mothers were in paid work were more likely to be smoking at age 15. When stratified by maternal education, the association between maternal employment and smoking was particularly strong among university educated mothers. Those whose mothers were never employed were 4-times more likely to smoke than those whose mothers were continuously employed between ages 3 and 15. The association between maternal employment and smoking was weaker in other strata of maternal education.

Conclusions:

Although maternal employment might have only a limited role in development of smoking behaviour of young adolescents, the association between maternal employment during childhood and young adolescents' smoking does exist and is particularly strong among those with university educated mothers.

Key messages:

- More than one third of Czech adolescents self-reported repeated attempt to smoke cigarettes or cigars or pipe at the beginning of new Millennium.
- Data suggest that adolescents whose mothers had not been employed were more likely to smoke than those of employed mothers.

Supporting child development to reduce child health inequalities in Belgium: a realist evaluation

Manon Beauvarlet

M Beauvarlet[1], M De Spiegelaere[1]
[1]Centre de Recherche en Approches Sociales de la Santé, Ecole de Santé Publique, Université Libre de Bruxelles, Brussels, Belgium
Contact: mbeauvar@ulb.ac.be

Background:

Reducing social inequalities in child health is a major challenge in Belgium. In Brussels, 40% of children are born in a household below the poverty line. The most efficient way to reduce social inequalities in health is to address them on a structural level, via public policies that improve families' income. But it is also proven that direct support of child development can reduce the risk of poverty in adulthood. Therefore, this study focuses on fields projects working directly with families living in poverty and aims to understand how, for whom and in which circumstances their actions can have effects on child's development.

Methods:

We conducted a realist evaluation of 30 field projects funded as part of the fight against child poverty and offering parenting support from prenatal period to the age of 6. Firstly, focus groups with the projects' workers were conducted to identify the underlying mechanisms in their interventions and the contexts facilitating or hindering these mechanisms to achieve the desired effects. Secondly, these Context-Mechanisms-Outcomes (CMO) configurations are validated with project beneficiaries through semi-directed interviews, using picture telling.

Results:

Despite the diversity of the actions carried out, common and transversal mechanisms are highlighted within 6 different CMOs that allow us to understand how and for whom those 30 projects work. Certain contexts - e.g. the characteristics of families, their feeling of freedom regarding the project, the density of projects network - can activate or hinder the mechanisms. We also note that workers tend to adjust their actions to support very vulnerable families for whom certain common mechanisms aren't working.

Conclusions:

This study, co-constructed through the collaboration of researchers and actors, could help workers to better understand and improve the mechanisms induced by their interventions, and stakeholders to recognise which projects are best suited to certain contexts.

Key messages:

- This realist evaluation enables to understand how for whom and in which circumstances field projects actions can have effects on child's development and therefore take part in child poverty reduction.
- The realist approach used in this study, through the parallel evaluation of 30 different field projects, allows to refine hypothesis from one project to another, ensuring transferability of results.

Sickness absence and disability pension in relation to first childbirth: three cohorts in Sweden

Krisztina Laszlo

C Bjorkenstam[1], C Orellana[2], K Laszlo[1,3], P Svedberg[1], M Voss[1], U Lidwall[4], P Lindfors[5], K Alexanderson[1]
[1]Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden
[2]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden
[3]Department of Public Health Sciences, Karolinska Institutet, Stockholm, Sweden
[4]Department for Analysis and Forecast, Swedish Social Insurance Agency, Stockholm, Sweden
[5]Department of Psychology, Stockholm University, Stockholm, Sweden
Contact: krisztina.laszlo@ki.se

Background:

Childbirth is suggested to be associated with elevated levels of sickness absence (SA) and disability pension (DP). However, knowledge about patterns of SA/DP before and after childbirth as compared to patterns among women who remain nulliparous is limited. We aimed to compare SA/DP across several periods among women with different childbirth status.

Methods:

We analysed three population-based cohorts of all women aged 18-39 years who had not previously given birth and who lived in Sweden on 31 December 1994, 1999, or 2004, respectively. We compared crude and standardized annual mean SA and DP net days during three years preceding to three years after the date of first childbirth, among women having (1) their first and only birth during the subsequent three years, (2) their first birth and at least another delivery, and (3) no childbirths before, nor during the study period.

Results:

Despite an increase in SA in the year preceding the first childbirth, women who gave birth, and especially women with multiple births, tended to have lower levels of SA/DP days throughout the years than women without childbirths. SA/DP days varied across age groups; young women (aged 18-24 years) without childbirths had fewer SA days, but more DP days than their same-aged counterparts who gave birth, regardless of year. These results did not differ across the three cohorts, suggesting that the results were not affected by period effects.

Conclusions:

Women with more than one childbirth had fewer days of SA and DP, as compared to women with one childbirth and to women having no births. Thus, childbirth does not seem to be associated with higher levels of SA and DP. Some of these results can be due to a health selection into giving birth, especially having more births.

Key messages:

- Except for the year before delivery, i.e., when pregnant, women giving birth had fewer SA and DP days than women with no births. Thus, childbirth does not seem to be associated with higher SA and DP.
- Women who had more than one childbirth had less SA/DP days than those with one childbirth.

Factors associated with the use of non-pharmacological analgesia for labor pain management

Jade Merrer

J Merrer[1,2], AA Chantry[1,2,3], B Khoshnood[1,2], B Blondel[1,2], C Le Ray[1,2,4], MP Bonnet[1,2,5]
[1]UMR 1153, Epope Team, CRESS, INSERM, Paris Descartes University, Paris, France

[4]Port Royal Maternity Unit, Department of Obstetrics, Assistance Publique-Hôpitaux de Paris, Paris, France
[5]Trousseau Hospital, Department of Anesthesia-Intensive Care, Assistance Publique-Hôpitaux de Paris, Paris, France
Contact: jade.merrer@inserm.fr

Background:

For a decade, pain labor management has evolved: if neuraxial analgesia remains the gold standard, non-pharmacological methods are developing. We aimed to identify individual and organizational factors associated with the use of non-pharmacological analgesia, combined or not with neuraxial analgesia.

Methods:

Women who attempted vaginal delivery with labor analgesia were selected from the 13,147 participants of the 2016 National Perinatal Survey. Labor analgesia was studied as follows: neuraxial analgesia only (NA), non-pharmacological analgesia only (NPA) or neuraxial and non-pharmacological methods combined (NA+NPA). Associations between individual and organizational characteristics were studied using a multilevel multinomial logistic regression.

Results:

Among the 9 231 women included, 62.4% had NA only, 6.5% had NPA only and 31.1% had NA+NPA. Both NPA and NA+NPA were associated with multiparity with antenatal classes, educational level $\geq$ 5 years post graduate, antenatal preference to deliver without NA, and delivery in public maternity units. The use of NPA only was positively associated with non-permanent availability of the anesthesiologist and with a high number of midwives per shift in maternity units. Contrastingly, NPA only was negatively associated with foreign nationality and oxytocin use for induction or augmentation of obstetrical labor. NA+NPA was positively associated with primiparity with antenatal classes, but negatively with inadequate prenatal care.

Conclusions:

Less than 40% of parturients used non-pharmacological analgesia during labor and for the most of them as complementary methods to neuraxial analgesia. NPA and NA+NPA were associated with individual characteristics as well as characteristics of management of labor and organization of maternity units. Non-pharmacological analgesia appears to be dedicated to high educated and well-integrated women in perinatal health care system.

Key messages:

- Less than 40% of parturients used non-pharmacological analgesia during labor and for the most of them as complementary methods to neuraxial analgesia.
- Non-pharmacological analgesia appears to be dedicated to high educated and well-integrated women in perinatal health care system.

Vaccination of classmates for an immunosuppressed child's protection in a school in the LHA Roma 1

Emanuela Maria Frisicale

M Marino[1], A Spadea[1], G Furia[1], EM Frisicale[1,2], MB Michelazzo[2], F Valentini[1], C Consoli[1], U Forte[1], S Bracci[1], M Goletti[1]
[1]Distretto 14, Local Health Authority - ASL Roma 1, Rome, Italy
[2]Istituto di Sanità Pubblica, Sezione di Igiene, Università Cattolica del Sacro Cuore, Rome, Italy
Contact: emanuela.frisicale@gmail.com

Issue/problem:

One of the duty of a State is to guarantee the protection of the health of all citizens, both safeguarding the sick individual needing care and protecting the healthy individual. An important objective of the vaccination prevention programs is to protect people most at risk of contracting infections because of their health conditions.

Description of the problem:

In April 2019 the District 14 of Local Health Autority Roma 1 was asked by a father of an immunosuppressed child (6 years old), worried about infectious diseases, to verify the safeness of his child school attendance (the first class of primary school). First, a list of the class mates was asked to the school, in order to check their vaccination status by interrogating the web based regional vaccination register. Then, the District asked to the school to plan a meeting with classmates' parents and teachers, in order to inform about the importance of a complete immunization both for the classmates and the immunosuppressed child protection.

Results:

Preliminary results show that, among 18 classmates, 77.8% had full vaccination coverage for the second dose measles and fourth dose whooping cough (not mandatory for children aged less than 7 years), 22.2% were immunized for chicken pox. Among the parents attending the meeting, 15 agreed to complete their children vaccination cycle, all the teachers agreed to undergo whooping cough and chicken pox vaccination in order to allow a safe school attendance to the immunosuppressed child. Parents and teachers were given an appointment in a vaccination center for the week following the meeting.

Lessons:

It is important to promote a real 'vaccination culture' starting from the school, in order to develop greater citizenship awareness about the potential of vaccinations and to contrast fake news and ignorance leading to dangerous prejudices.

Key messages:

- The active collaboration between institutions (sanitary and school) allows, through the integration between different competences, to achieve health objectives to protect the community.
- Talking to pupils' parents about infectious diseases and their prevention makes it possible to increase knowledge and therefore awareness of the importance of adult and children health protection.

Health and well-being of parents with 4-year-old children – a nationwide study in 2018 in Finland

Reija Klemetti

R Klemetti[1], M Vuorenmaa[1], R Ikonen[1], J Oksanen[1], J Lammi-Taskula[1]
[1]Chidren, Adolescent and Families, National Institute for Health and Welfare, Helsinki, Finland
Contact: reija.klemetti@thl.fi

Background:

A nation-wide data collection on small children and their families' health and well-being has been lacking in Finland.

The aim of this study was to examine health and determinants of health among parents with a four-year-old child.

Methods:

A nation-wide study for 4-year-old children (N = 8720) and their parents (N = 10 737) conducted in 2018. The families were recruited by public health nurses at child health clinics. Both parents had a possibility to answer a questionnaire considering questions on health, well-being and service use. General health of the parent was measured by one question (How do you find your general state of health?), depressive disorders by PHQ-2 and mental health by MHI-5. Data were analyzed by cross-tabulation. Results of logistic regression will be presented in the conference.

Results:

Most participants were female (72%) and most families had two adults (93%). Mean age was 35 years and 58% were highly educated. Around 10% reported their health as average or poor, 19% had had depressive disorders within 12 months, and 6% had experienced mental distress. Single parents reported mental distress and depressive disorders significantly more often than the other parents. Average or poor health was reported significantly more often by female parents. Those with average or poor health or depressive disorders were significantly more likely to have one child, upper secondary education or less, or be outside of work. They felt themselves significantly more often lonely and unsatisfied with their life and family's economic situation. They were also significantly more likely to report need of support for their own parenthood and partnership.

Conclusions:

Health challenges among the parents were quite similar than those among the adults in same ages. However, detailed analysis is needed to find out the specific determinants affecting the parents and whole family's life to be able to better support the families.

Key messages:

- Most parents with children aged 4-year-old were healthy and satisfied with their life.
- The parents having poor physical or mental health had also challenges in family life.

Umbilical cord care through community-based distribution of chlorhexidine in rural Sindh, Pakistan

Mohammad Shah

M Shah[1], *Q Jamali*[2], *F Aisha*[2]
[1]Save the Children US, Lutherville, USA
[2]Health and Nutrition, Save the Children, Karachi, Pakistan
Contact: mshah@savechildren.org

Background:

Unsafe practices such as cutting umbilical cord with unsterilized instruments and application of harmful substances, are in practice in many rural areas of Pakistan, and associated with high risk of neonatal sepsis and mortality.

Methods:

We conducted an implementation research in 2015 in Tharparkar district, in Sindh province of Pakistan to understand the feasibility and acceptability of community-based distribution of chlorhexidine (CHX) in rural Pakistan. For this cohort group-only study, 225 lady health workers (LHWs) enrolled 495 pregnant women. Enrolled women received 4% CHX gel and user's instructions for newborn cord care. The LHWs also counseled women on the benefits and correct use of CHX. Study enumerators collected data from CHX receiving women 3 times: at around 2 weeks before delivery, within 24 hours after delivery, and on the 8th day after delivery. We implemented this study jointly in collaboration with Ministry of Health in Sindh province, Pakistan.

Results:

Among enrolled participants, 399 women (81%) received only the first visit, 295 women (60%) received first two visits and 261 women (53%) received all three visits by enumerators. Among 399 women, who received CHX gel, counseling on its use and were respondent to the first round data collection, 78% remembered that the CHX gel to be applied to cord stump and surrounding areas immediately after birth; but less than a third (29%) forgot the need to keep the cord clean and dry. Among 295 respondents in the first two rounds of data collection, who delivered at home, 97% applied CHX to cord stump on the first day.

Conclusions:

Community-based CHX distribution by LHWs, along with counseling to recipient women, resulted in a high rate of cord care with CHX among newborn delivered at home. Results from this study may help program implementers to consider expanding this intervention for improving newborn cord care on the first day of life in Pakistan.

Key messages:

- Community-based distribution of chlorhexidine for newborn cord care appears as highly acceptable and feasible in rural communities in Pakistan.
- Relevant program policy supporting community-based CHX distribution along with counseling by LHW may help expanding coverage of newborn cord care in rural communities in Pakistan.

A vaccination campaign in a Roma community in Rome: an experience of the Local Health Autority Roma1

Emanuela Maria Frisicale

A Spadea[1], *M Marino*[1], *F Valentini*[1], *G Furia*[1], *EM Frisicale*[1,2], *MB Michelazzo*[2], *C Consoli*[1], *U Forte*[1], *S Bracci*[1], *M Goletti*[1]
[1]Distretto 14, Local Health Authority - ASL Roma 1, Rome, Italy
[2]Istituto di Sanità Pubblica, Sezione di Igiene, Università Cattolica del Sacro Cuore, Rome, Italy
Contact: emanuela.frisicale@gmail.com

Issue/problem:

About 8,000 Roma and Sinti live in the city of Rome, distributed in 33 settlements. This population is particularly at risk of health problems, due to social marginality and reduced access to health and social services. An important challenge for public health is therefore to guarantee and improve the right to health and the availability of health care. In Italy, a new vaccination law was approved in July 2017 and 10 vaccinations became mandatory for minors attending schools.

Description of the problem:

In 2018 the District 14 of the Local Health Authority Rome1 (LHA Rome1) organized a vaccination campaign for the Roma and Sinti community being in its area. The aim of the campaign was to analyse the vaccination status of children under-18 living in the camp, based on the local police census data, crossed with the web based regional vaccination registry, to offer free vaccination for those without a regular status, in order to allow school attendance.

Results:

Among 109 children living in the targeted Roma and Sinti camp, only 6 (5.5%) had a regular vaccination status according to the Italian law. Two different vaccination opportunity were offered to the community during 2018: a dedicated vaccination session in the local vaccination center, during which 6 children were vaccinated; four vaccination days offered directly at the Roma camp (a total of 53 children were vaccinated). At the end of 2018, the new Police census identified 114 minors resident in the camp instead of 109; of these, 48 (42.1%) had reached a regular vaccination status.

Lessons:

Addressing hard-to-reach communities in order to improve the access to health and social services is one of the LHA objectives. The intervention performed in the Roma camp was also an opportunity to promote the importance of vaccination and to inform the target community about various LHA services, in particular maternal and infant services, including those for Temporarily Present Foreigners.

Key messages:

- The interventions performed straight into communities living in unfavorable health and social conditions are useful to improve the access to health and social services.
- Vaccination of people living in a social marginality is an important challenge for public health in order to guarantee specific protection measures and promoting the right to health.

Sexual behaviour and attitudes among university students in Zagreb

Marjeta Majer

M Majer[1], *B Puškarić Saić*[2], *V Musil*[1], *R Mužić*[3], *N Pjevač*[1], *V Jureša*[1]
[1]University of Zagreb, School of Medicine, Andrija Štampar School of Public Health, Zagreb, Croatia
[2]Andrija Štampar Teaching Institute of Public Health, Department of School and Adolescent Medicine, Zagreb, Croatia
[3]University of Zagreb, School of Medicine, Zagreb, Croatia
Contact: mmajer@snz.hr

Background:

Sexual behaviour of youth could have reproductive health outcomes with an impact on individual and general population health. The aim of this study was to determine sexual behaviour and attitudes among first year university students in city of Zagreb, Croatia.

Methods:

Study included 298 first year students (61% of females) of Medical School University of Zagreb and 124 students (75% of females) of Catholic University of Zagreb in academic year 2017/2018. Data were collected by anonymous questionnaire School Health Survey, and analysed by descriptive statistics.

Results:

Significantly higher proportion of Catholic University students have had sexual intercourse comparing to medical students of University of Zagreb (48% vs. 36%, $P = 0.019$). The age of first sexual intercourse for the most of students was from 16-18 years (73% of Catholic University students, and 79% of medical students). Contraception was always used among 54% of Catholic University students, and 67% of medical students, and never used among 11% and 4% of them respectively. Most of the students have gained information about human sexuality from the internet (26% of Catholic University students, and 30% of medical students), followed by friends (18%) and parents (11%) for Catholic University students, and television (25%) and friends (14%) for medical students. Most students expressed the attitude that sex education should be introduced in secondary schools (31% and 36%, respectively), followed by both, in primary and secondary schools (21%, and 30% respectively). Fourteen percent of Catholic University students and 7% of medical students thought that sex education should not be introduced to schools.

Conclusions:

Results showed risky sexual behaviour of university students, especially Catholic University students, indicating the need of continuous education on reproductive health among youth.

Key messages:

- Results indicate the need of intervention and continuous education on reproductive health among university students in Zagreb, Croatia.
- Results showed insufficient use of contraception especially among Catholic University students indicating the need of education on reproductive health among medical and nonmedical students.

How do male students perceive their role in contraception and the protection against STDs?

Claudia Van Der Heijde

CM Van Der Heijde[1], *M Veldhoven*[1], *P Vonk*[1]
[1]Student Health Service, University of Amsterdam, Amsterdam, Netherlands
Contact: c.m.vanderheijde@uva.nl

Background:

A lot of research has been done on women and contraception. How men perceive their role regarding contraception is largely unknown. Previous research shows that factors like intentions, communication and knowledge are of importance. The aim of this study is to get more insight that could provide us with more starting points for preventing unwanted pregnancies and STDs.

Methods:

Eight semi-structured interviews with male students from Amsterdam, The Netherlands (aged 18-25, different study programs) were conducted based on a, previously developed, topic list. Convenience sampling was used to select respondents. The interviews were processed with thematic content analysis. Open, axial, and selective coding was used to analyze the interviews.

Results:

Four themes emerged from the data: openness of parents, making an informed decision, prevention of pregnancy and STDs and durance of relationship. Men do not have a clear view on their role in contraception regarding responsibility and are still struggling with the autonomy of their partner, also in relation to the length of the relationship. When in a relationship they feel their role should be to support and communicate with their partner, but not to make the final contraceptive choice. When not in a committed relationship, men feel their role is solely to protect themselves against fatherhood and, to a much lesser extent, STDs.

Conclusions:

Communication is key in preventing unwanted pregnancies and STDs, and working towards a shared responsibility. Following up on the role of parents in communicating well about these subjects, both men and women should take their responsibility in communicating. Furthermore, fear of unwanted pregnancy seems much larger than fear for STDs for male students. These subjects can be addressed in a university institutional context in a variety of ways (f.i. via flyers, projects, student counselors, student health services).

Key messages:

- More attention for the role of both men and women in communicating about contraception and STDs is necessary in a student population within the university institutional context.
- More attention for the dangers of STDs and the importance of protection against STDs is necessary in a student population within the university institutional context.

What are the determinants of body image distortion and dissatisfaction among Tunisian teenagers?

Houda Ben Ayed

H Ben Ayed[1,2], *J Jedidi*[1,2], *F Cheikhrouhou*[2], *A Ayadi*[2], *S Yaich*[1], *J Damak*[1]
[1]Community Health and Epidemiology, Hedi Chaker University Hospital, University of Sfax, Sfax, Tunisia
[2]Train the Trainees, CONFIDE Project, University of Sfax, Sfax, Tunisia
Contact: drhoudabayed@gmail.com

Background:

Body image (BI) is considered as central to many aspects of human functioning including emotions, thoughts, behaviors and relationships. This study aimed to investigate the prevalence and the main determinants of distortion and dissatisfaction among teenagers.

Methods:

This was a cross-sectional school-based study using a self-administered questionnaire, conducted among a randomized sample of 1300 school-adolescents in Southern Tunisia, 2018. BI perception was assessed by the Stunkard Figure Rating Scale.

Results:

Among 1210 respondents (93%), BI distortion and dissatisfaction prevalence were 44.8% and 42.4%, respectively. Multivariate analysis showed that 16-18 years age group (Adjusted Odds Ratio (AOR) = 1.28; $p = 0.046$), low family financial situation (AOR = 1.88; $p = 0.014$), as well as high frequency of eating pasta (AOR = 1.3; $p = 0.04$) and fast-food consumption (AOR = 1.7;p = 0.042) were independently associated with under-estimated BI. Skipping breakfast (AOR = 1.9; p = 0.017) and having one obese parent (AOR = 1.9;p = 0.01) were independently associated with higher frequency of over-estimated BI. For BI dissatisfaction, independent factors associated with desire to lose weight were female gender (AOR = 1.53; p = 0.007), high family financial situation (AOR = 2.1,p = 0.008) and having one parent obese (AOR = 2.21,p<0.001). Frequent fast-food consumption (AOR = 1.9, p = 0.038) and eating between meals (AOR = 1.57,p = 0.01) were associated with higher desire to gain weight.

Conclusions:

Our study highlighted a substantially high prevalence of BI distortion and dissatisfaction among adolescents. Their determinants included socio-demographic factors and lifestyle behaviors. Increased awareness among parents and public health planners may help adolescents improve accuracy of BI attitudes.

Key messages:

- BI distortion and dissatisfaction are pervasive problems that increased negative affect in adolescents.
- Promotion of healthy lifestyle including balanced diet and physical activity is warranted.

External resources of resilience in association with the alcohol use among early adolescents

Lenka Abrinková

L Abrinkova[1], O Orosová[2], M Bacikova-Sleskova[2], M Štefaňáková[1], B Gajdošová[2]
[1]Department of Psychology, Pavol Jozef Šafárik University in Košice, Košice, Slovakia
[2]Department of Educational Psychology and Psychology of Healt, Pavol Jozef Šafárik University in Košice, Košice, Slovakia
Contact: lenka.abrinkova@gmail.com

Background:

This study aimed to explore the role of external resources of resilience in explaining the alcohol use in past 30 days among early adolescents.

Methods:

A representative sample of 653 (52.9% girls) early adolescents (mean age =11.72 at T1; mean age = 13.09 at T5) was collected within a five wave repeated measure design with a baseline(T1), 3-month follow up(T2), 6-month (T3), 12-month(T4) and 18-month follow-up(T5). Alcohol use (AU) in the past 30 days was measured by a questionnaire of the international study ESPAD. School support (SS), school activities participation (SAP), home support (HS) and home activities participation (HAP) were measured by the Resilience Youth Development Module and represented external resources of resilience. Respondent's AU (dichotomized: 0-not used, 1-used) served as the outcome variable and external resources of resilience served as the independent variables. Binary logistic regressions were used to analyze the data.

Results:

At T1, SS (95% CI = 0.77-0.96; p<0.01) was associated with lower AU while SAP (95% CI = 1.00-1.36; p<0.05) was associated with higher AU. At T2, SS (95% CI = 0.73-0.94; pα<0.01) and HS (95% CI = 0.70-0.98; pα<0.05) were associated with lower AU. AT T3, no significant association was found with AU and finally at T4 and T5 only HS (95% CI = 0.81-1.00; T4 = pα<0.05), (95% CI = 0.78-0.96; T5 = pα<0.01) remained significantly associated with lower AU at T4 and T5 while controlling for alcohol use at T1. AU increased significantly across the five waves (pα<0.01). Gender differences in AU were found only at T1 (p<0.01) with boys scoring higher.

Conclusions:

The 5 measurement revealed a trend of the external resources of resilience in AU shifting from the school environment to the home environment. Moreover, it seems that SAP is associated with a higher probability of AU through more opportunities for group activities which are often associated with AU.

Key messages:

- School environment plays an important role in explaining AU in younger early adolescents. Home environment plays an important role in explaining AU in older early adolescents.
- The results point to an increasing trend in alcohol use among early adolescents.

Childhood life events and disturbed eating behaviors in a population-based cohort in the Netherlands

Robin Thomas

R Thomas[1,2], E Diemer[2,3], R Siliquini[1], PW Jansen[2,4]
[1]Department of Public Health Sciences, University of Turin, Turin, Italy
[2]Department of Child and Adolescent Psychiatry/Psychology, Erasmus MC-University Medical Center, Rotterdam, Netherlands
[3]The Generation R Study Group, Erasmus MC-University Medical Center, Rotterdam, Netherlands
[4]Department of Psychology, Education, and Child Studies, Erasmus University Rotterdam, Rotterdam, Netherlands
Contact: robin.thomas@unito.it

Background:

Adversities such as maltreatment and physical and emotional abuse are recognized risk factors for eating disorders (EDs) in adolescents and adults, but whether such adversities are also associated with eating behaviors in childhood has been less explored. Our aim was to examine whether a wide range of life events can predict emotional overeating and restrained eating in childhood, which are potential precursors of EDs.

Methods:

The study is embedded in Generation R, a prospective population-based cohort. The sample included 4653 children aged 10 years. Emotional overeating was assessed with the Children's Eating Behavior Questionnaire, and restrained eating with the Dutch Eating Behavior Questionnaire. Mothers reported the occurrence of 24 adverse events in their offspring's childhood. Regression analyses were conducted, both unadjusted and adjusted for gender, ethnicity, and parental education and psychopathology.

Results:

Unadjusted models showed that a higher number of life events is associated with more emotional overeating and more restrained eating; effect estimates attenuated slightly in the adjusted model, but remained significant (per 1 more life event: B = 0.05, 95%CI 0.02-0.08; B = 0.04, 95%CI 0.02-0.07, respectively). Particularly, participants who experienced at least 3 life events had high levels of emotional overeating and restrained eating (adjusted model: B = 0.20, 95%CI 0.06-0.33; B = 0.21, 95%CI 0.08-0.33, respectively). The specific maltreatment related life events were not significantly associated with eating behaviors, probably due to low prevalence of these events (n = 149).

Conclusions:

This novel, population-based study shows that early life adversities may predict disordered eating behaviors in childhood. The results are in line with clinical studies on life events and EDs. If the studied eating behaviors are indeed precursors of EDs, these results may offer potential for prevention and early intervention to avoid the development of full-blown EDs.

Key messages:

- Eating disorders account for more than 2% of the global disease burden, thus representing a major Public Mental Health topic in the EU; more and new measures are required for early detection purposes.
- Life adversities predict disordered eating behaviors in childhood, which are considered precursors of eating disorders: early detection of this association may avoid development of eating disorders.

Raising young people's awareness on sexual and reproductive health issues

Maria Papadakaki

M Papadakaki[1], M Plevri[1], K Vagionaki[1], G Papadomanolakis[2], R Androulaki[3], G Tsiritas[4], LM Koutroumanou[4], G Aleiferis[4], M Vasilakis[1], J Chliaoutakis[1]

[1]Department of Social Work, Hellenic Mediterranean University of Crete, Heraklion, Greece
[2]Primary Health Care Centre of Chania, Chania, Greece
[3]Primary Health Care Centre of Heraklion, Heraklion, Greece
[4]Medical School, University of Crete, Heraklion, Greece
Contact: mpapadakaki@yahoo.gr

Issue/problem:

Despite the high prevalence of sexually transmitted diseases(STIs) and abortions among Greek youth, sexuality education is not yet part of the curriculum of Greek schools and the Greek family is not ready to address these issues with comfort.

Description of the problem:

A ''one-stop information point'' was organized for one week in major cities of Crete Region as part of a community health program, which was funded by the Regional Authority of Crete to address ''Gender Equality in the Region of Crete within 2018-2020''. The project aimed at increasing young people's awareness of sexual health issues using a ''peer education'' approach and a youth-friendly information package. Undergraduate students from health, mental health and social care professions acted as volunteers upon receiving a rigorous 2-day training by sexual and reproductive health experts. The questions to be answered by the project were: ''What are the main concerns of adolescents regarding their sexual health? How much satisfaction could adolescents gain by a ''one stop information point'' and a youth friendly ''information package'' offered by peers?

Results:

Serious information gaps regarding contraception and STI's and a number of stereotypes regarding healthy relations and sexual orientation have been recorded. Gender dysphoria is still an issue that remains unaddressed among young people. A youth-friendly website (LaHeRS Lab) and short videos are now available as part of the project to facilitate young people's access to information. A large social media network of young people interested in sexual health issues has been formed locally and is growing nationally. The intervention was received with satisfaction.

Lessons:

''One-stop information centres'' and ''peer education'' have been an ideal combination to address sensitive issues among young people.

Key messages:

- Knowledge gaps and unsafe sexual practices are prevalent among adolescents.
- Sexuality education should be offered in early school life.

Is school furniture design a contributing factor to low back pain in adolescents?

Houda Ben Ayed

H Ben Ayed[1,2], J Jedidi[1,2], F Cheikhrouhou[2], A Ayadi[2], S Yaich[1], J Damak[1]
[1]Community Health and Epidemiology Department, Hedi Chaker University Hospital, University of Sfax, Sfax, Tunisia
[2]Train the Trainees, CONFIDE Project, University of Sfax, Sfax, Tunisia
Contact: drhoudabayed@gmail.com

Background:

Recent evidence showed that low back pain (LBP) is frequent among youth. Individual etiologic factors are most often associated with musculoskeletal overuse and altered postural control. This study aimed to evaluate the association between school furniture design and LBP in school-adolescents.

Methods:

A cross-sectional study was conducted using a self-reported questionnaire distributed to school-adolescents aged 12-18 years, in Southern Tunisia, 2018. We performed a stratified three-step sample to obtain a representative sample of 1400 subjects.

Results:

The response rate was 87.2% (1221 students). The mean schoolbag weight was 3±1.3 kg. The schoolbag to body weight ratio was 0.05±0.03. The main method of carrying a schoolbag was on both shoulders (57.2%). During the last 3 months, LBP was reported in 391 cases (32%). Multivariate analysis using logistic regression showed that high-school grade was independently associated with LBP (Adjusted Odds Ratio (AOR) = 2.7;95% CI = [1.9-3.7];p<0.001). Classroom furniture and layout design independently associated with LBP included too low seat backrest (AOR = 1.4;95% CI = [1.12-1.87];p = 0.005), too far seat to black(board) distance (AOR = 1.5;95% CI = [1.1-2.2];p = 0.041), schoolbag to body weight ratio ≥10% (AOR = 1.7;95% CI = [1.2-2.4]; p = 0.002) and carrying schoolbag for 30-60 minutes (AOR = 1.48;95% CI = [1.1-2.1]; p = 0.029). Otherwise, carrying school bag by hand (AOR = 0.25; 95% CI = [0.07-0.89]; p = 0.033) was found to be independently associated with lower prevalence of LBP complaints.

Conclusions:

Current design of school furniture is not compatible with the adequate purposed dimensions in students. It increased substantially the risk of LBP, which emphasizes the need for multi-disciplinary approach involving teachers, policy makers and health care professionals.

Key messages:

- School related LBP may threaten the physical performance and the social life of adolescents.
- Revising school environments and radical ergonomic interventions are mandatory.

Prevalence of Italian children living in food insecure households and their health status

Drieda Zace

D Zace[1], C de Waure[2], A Teleman[1], L Reali[3], ML Di Pietro[1]
[1]Institute of Public Health, Section of Hygiene, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Department of Experimental Medicine, Università degli Studi di Perugia, Perugia, Italy
[3]Associazione Culturale Pediatri Lazio, Rome, Italy
Contact: drieda_zace@hotmail.com

Background:

Food insecurity poses a major threat to population's health status. Children, if affected, are particularly vulnerable to the possible sequels of food insecurity. Considering that, we aimed to assess the prevalence of children (born in Italy, from Italian parents) living in food insecure households and the association with their health and socio-economic conditions.

Methods:

The study was conducted from January 2017 to December 2018 in pediatric offices. Parents answered to the 18-items of the Household Food Security Index, 8 of which specifically concern children. Households were classified in 4 categories: very low, low, marginal and high food security, creating then a dichotomized variable (food secure and insecure). Pediatricians answered a dedicated questionnaire on children's health status. We used logistic regression to assess the socio-economic variables predicting food insecurity and chi2 test to evaluate the association between food insecurity and children's health status.

Results:

Based on parents' answers, among 573 households with children, 15.4% were food insecure. Food insecurity was associated to lower parent's education and employment, worse household's economic condition, higher number of children within a family and geographic location (living in south Italy rather than north). There was a significant association between food insecurity and the presence of visual, relational, psychomotor, dental and physical impairments in children.

Conclusions:

Almost 1 Italian child in 7 lives in food insecure households. Children living in food insecure households have higher probability of having physical, mental and social health problems. Considering the impact on children's health, food insecurity emerges as a public health issue and should be addressed through the appropriate measures.

Key messages:

- Food insecurity among children represents a public health issue even in a developed country such as Italy, affecting children's present and future health.
- Policy makers should consider screening children for food insecurity and taking appropriate actions, especially for the at-risk population.

Weight Control Practices in Turkish Adolescents and Factors Related with Over- Weight and Obesity

Ayse Ergun

B Atintas Sert[1], A Ergun[1]
[1]Public Health Nursing, Marmara University, Istanbul, Turkey
Contact: ayergun@gmail.com

Backgrounds:

Over-weight and negative body perception that may develop during adolescence period cause many slimming experiences, especially the diet and as the state of discontent increases, the methods used are more unhealthy and dangerous. This study was conducted to determine the weight control practices and the factors related to over-weight-obesity in Turkish adolescents.

Methods:

This cross-sectional study was conducted with 900 high school students aged between 14-18. The data were collected by using an introductory form including questions about socio-demographic characteristics and weight control, eating attitude test (EAT-26), Bergen Insomnia Scale and height-weight.

Results:

In this study, it was found that 9.1% of the adolescents were overweight, 8.2% of them were obese, and 32.9% of them had a risky eating behavior (EAT-26 score > 20). It was found that 87.7% of adolescents who are overweight-obese and 40% of those with normal weight were wanted to lose weight. It was determined that 70.4% of adolescents exercise for weight control, 63.6% of them increased fluid consumption and 16.6% of them used weight loss dietary supplement. Adolescents who were overweight-obese had a higher proportion of those with a risk of eating behavior (EAT> 20) and those with insomnia problems than those with normal weight ($p < 0.05$). The factors related to overweight and obesity were found in female adolescents; standing snacking, angry negative moods and sometimes consuming irregular meals between meals, whereas in male students; watching TV, working while eating, standing snacking, late-night eating and insomnia ($p < 0.05$).

Conclusions:

It was determined that the majority of overweight-obese students wanted to lose weight and some of those had a risky eating habits and preferred unhealthy methods for weight control. These results indicate that was need programs of healthy weight control and prevention of obesity in the schools.

Key messages:

- Adolescents who were overweight-obese had a higher proportion of those with a risk of eating behavior (EAT> 20).
- There is a need for public health programs on healthy weight control and weight regulation practices for adolescents.

Risk factors of pregnancy morbidity in migrant women from Subsaharan Africa

Holy Bezanahary

H Bezanahary[1], B Gutierrez[1], S Dumonteil[1], P Coste Mazeau[2], JL Eyraud[2], PM Preux[3], AL Fauchais[1], K Ly[1], Y Aubard[2]
[1]Internal Medicine, CHU Dupuytren 2, Limoges, France
[2]Obstetric Department, CHU, Limoges, France
[3]UMR 1094 NET, INSERM, Limoges, France
Contact: h.bezanahary@wanadoo.fr

Reduction of maternal mortality remains a major public health issue worldwide. In France, the latest national confidential enquiry regarding maternal mortality (2010-2012) stated a ratio of 10 /100 000 livebirths whereas the goal was 5/100 000. The risk of death among pregnant women from Subsaharan Africa (SSA) was 3 times higher.

We performed a monocentric observational retrospective study from 01/01/2009 to 01/09/2016 in order to better understand the factors of maternal morbidity among SSA pregnant women. Demographic characteristics as well as pregnancy outcomes were collected. Antenatal clinics attendance was scored (+1 if positive, +1 if done following the recommended schedule). A total 1 489 (7%) out of 20 755 pregnancies were registred among SSA women. Mean age was 29 years (14-48), mean gestity/parity were respectively 3.5 and 1.8. About 38% of pregnancies occured in overweight or obese women. Obstetrical complications were seen in 542 (36%) pregnancies: gestational diabetes (n = 206, 36,4%), hypertensive disorders (n = 122, 8,2%), 19 had both. Pre-eclampsia represented 4%, sepsis 5%, premature rupture of membrane 5% and post partum haemorrhage 3%. Livebirths was high (97%) with a mean gestational age of 37(22-41), a mean birth weight of 3150g (500-5000). The unique maternal death in this cohort was due to amniotic fluid embolism. Complication risk factors were age (30 versus 28 years; $p < 0.0001$), BMI (26 versus 25 kg/m2; $p < 0.0001$), past history of chronic hypertension and pregestational diabetes ($p < 0{,}001$). Furthermore, the score of antenatal care attendance was low in those who presented pregnancy morbidities ($p = 0.0006$) (adjusted with age, BMI> 25 and chronic hypertension).

Higher risk of maternal morbidity among SSA women is not only explained by individual risk factors but also by a lack of compliance to the recommended antenatal care even if they live in France. Further investigations including sociological studies are therefore needed.

Key messages:

- Maternal mortality and morbidity are higher among migrant women from Subsaharan Africa.
- Our study highlights a non compliance to the recommended antenatal care surveillance among risk factors.

Features of establishment of early lactation in women who gave birth after in vitro fertilization

Artyom Gil

P Samchuk[1], Y Rozalieva[1], A Gil[1]
[1]I.M.Sechenov First Moscow State Medical University, Moscow, Russia
Contact: artyom5@mail.ru

Background:

Breastfeeding gives babies the best possible start in life and breastmilk works like a baby's first vaccine. Pregnancy resulting from IVF is often associated with placental insufficiency in which the hormone-producing function of placenta can be compromised that may result in reduced lactogenesis. The aim was to study the emergence of early lactation after IVF in women with a history of infertility.

Methods:

The study involved 34 women after IVF with a singleton full-term pregnancy with a history of tubal-peritoneal infertility. Control group comprised of 47 women with naturally occurred pregnancy. Delivery occurred naturally. All women were assessed for hormonal function of placenta for a period of 16-18, 28-32, and 37-38 weeks of pregnancy. The average daily amount of milk on a 5th day after delivery was measured.

Results:

In the IVF group vs. control group there was a decrease in the production of hormones by the placenta (progesterone, estriol, placental lactogen) preparing the mammary glands for lactation ($p < 0.05$). At gestational age of 16-18 weeks progesterone level in IVF group was 172.2±10.72 nmol/l; 28-32: 274.2±8.45 nmol/l; 37-38 weeks: 343.2±9,1 nmol/l. The level of estriol at 16-18 weeks was 2.87±1.42 ng/ml; 28-32: 10.94±0.6 ng/ml; 37-38 weeks: 25.21±0.22 ng/ml. Placental lactogen at16-18 weeks: 1.15±0.2 nmol/l; 28-32: 6.39±0.69 nmol/l; 37-38 weeks: 7.23±0.59 nmol/l. On day 5 normal lactation was observed in 21(62%) and 43(91.5%) women in IVF and control group, respectively ($p < 0.05$).

Conclusions:

Increased number of cases of hypolactation was observed in women after IVF, which was associated with decrease in the hormonal function of placenta. Women who have given birth to children after IVF require special attention from the side of medical personnel and from loved ones in the early stages of establishment of breastfeeding.

Key messages:

- IVF is a risk factor for hypolactation, which is associated with placental hormone-producing insufficiency.
- Women who have given birth after IVF require support aimed at promotion of early lactation and breastfeeding.

Improving maternal healthcare in Georgia

Natia Skhvitaridze

N Skhvitaridze[1,2], A Gamkrelidze[2], T Lobjanidze[1]
[1]School of Health Sciences, The University of Georgia, Tbilisi, Georgia
[2]National Center for Disease Control and Public Health, Tbilisi, Georgia
Contact: natiaskh@yahoo.com

Improvement of reproductive health is a worldwide priority. Maternal and perinatal mortality and morbidity are frequently used as measure of quality of the healthcare. Thus, reduction of maternal morbidity and mortality are important goal for the SDGs. Hence, maternal and new-borns health are crucial to report accurately. The key requirement for progress is to have as much precise data as it is possible. Several tools are developed for quality surveillance; among them is the medical birth registry.

Georgia is a developing country which recently had healthcare in transition. Over the last decade, Georgia's health sector has improved quality and embraced evidence-based medicine. Transformation and progress attributed reproductive healthcare. Country elaborated strategic plan and set achievable target for maternal and children's mortality ratios for 2030. Georgia developed national maternal surveillance system. However, country has been lacking precise, comprehensive, and longitudinal data dealing with the reproductive health. Thus far, data on associated health services mainly derived from the sporadic on-demand surveys. Routine info on mortality and morbidity were available as aggregated data with a lack of epidemiological analysis.

In order to provide proper reproductive health profile, Georgia created a nationwide medical birth registry (GBR). GBR has made it possible to create a precise epidemiological analysis and to ensure the evidence-based reporting. To improve epidemiological research capacity, PhD projects were implemented a year after the GBR started operation, in the frame of cooperation of Norwegian and Georgian Universities. Moreover, universities initiated tracks for master students to have internship and graduate thesis in GBR related topics.

Overarching goals of the GBR are numerous. Although compilations of statistics and ensuring scientific bases for advice through generated researches are beneficial for universities and country as well.

Key messages:

- Studies, based on transparency of highly accurate medical statistics gives possibility for effective implementation of evidence-based public health interventions.
- Recommendations provided by registry based studies have a pivotal role in formulation and revision of relevant public health strategies.

Association between maternal factors and appropriate medication for nursery school children in Japan

Natsuyo Yanagi

N Yanagi[1], H Satoh[1,2], Y Sawada[1]
[1]Laboratory of Drug Lifetime Management, Graduate School of Pharmaceutical Sciences, The University of Tokyo, Tokyo, Japan
[2]Interfaculty Initiative in Information Studies, Graduate School of Interdisciplinary Information Studies, The University of Tokyo, Tokyo, Japan
Contact: ntyanagi@gmail.com

Background:

Inappropriate medication use for children by caregivers has been reported in Japan. We focused on the factors which could be associated with health literacy (HL) and knowledge of medication (KM). We aimed to examine the association between appropriate use for nursery school children and maternal socioeconomic status (SES) or behavior related to medication adherence among mothers in Japan.

Methods:

The data regarding the conditions of medication for children (aged from six months to six years old) at home and in nursery school by the online survey from April to May 2019 was used. Maternal SES, such as education, occupational status, and economic conditions, were asked via a self-administered questionnaire. Maternal behaviors were measured using a 5-point Likert scale and classified into two groups. HL and KM were scored and divided into two categories. Appropriate medication use was evaluated using a 5-point Likert scale for the statement "I give my child medicine as per instructions," and the answers were classified into two groups. Poisson regression was employed to investigate the association. Age, maternal SES, chronic disease of children, birth order, HL, and KM were used as covariates.

Results:

A total of 233 (38.8%) of 600 mothers aged 24-48 years, reported appropriate medication use for children. None of the maternal SES was statistically significant. After adjustment, the individuals, who consent to prescribed medications for children, were 2.16 times (95% confidence interval [CI]:1.64-2.86) more likely to use medicine appropriately compared with their counterparts. 'To be able to consult with pharmacists' were also statistically significant (Prevalence Ratio = 2.14, 95% CI:1.63-2.81).

Conclusions:

The mothers, who consent to prescribed medications for children, who consult with pharmacists were more likely to use medicine appropriately. Community pharmacists could support those to improve their skills.

Key messages:

- The maternal behaviors related to adherence were associated with appropriate medication for children among Japanese mothers, although none of the maternal SES was statistically significant.
- Community pharmacists could support mothers and contribute appropriate medical treatment for children.

Screening for celiac disease in school aged children in Croatia

Tatjana Petricevic-Vidovic

TPV Petricevic-Vidovic[1], VM Musil[1,2], ES Sičaja[1], ZM Mišak[3]
[1]Department of School and Adolescent Medicine, Andrija Stampar Teaching Institute of Public Health, Zagreb, Croatia
[2]Department of Social Medicine and Health Care Organization, University of Zagreb, School of Medicine Andrija Štampar School of Public Health, Zagreb, Croatia
[3]Department of Gastroenterology, Hepatology and Nutrition, Children's Hospital Zagreb, Zagreb, Croatia
Contact: tatjana.petricevic-vidovic@stampar.hr

Background:

Celiac disease primarily affects small intestine and occurs as an immune-based reaction to dietary gluten in wheat, barley and rye. There has been a significant increase in prevalence and an increase in diagnosis rate due to diagnostic tests improvements. Celiac disease can present with gastrointestinal and non-gastrointestinal abnormalities, but also many individuals may have no symptoms at all. Early diagnosis of celiac disease is essential, because untreated disorder may result in serious complications. The aim of this study was to detect celiac disease in asymptomatic school-aged children and to determine prevalence rate.

Methods:

Cross sectional study was conducted on a sample of 2000 children in school year 2018/2019 in school health service. The sample comprised 15.8% of elementary school first grade population in City of Zagreb, aged 6-7 years. SimtomaX in-vitro rapid screening test was used to detect IgA and IgG deamidated gliadin peptide and/or IgA deficiency. Children with positive tests were referred to clinical diagnostic. Data were analysed by descriptive statistic.

Results:

The study comprised 1404 children (51% girls, response rate 70%). Positive result was found in 5.6% children (42 girls and 37 boys). Up to now, celiac disease was confirmed with duodenal biopsy in 0.5% asymptomatic children (3 girls, 4 boys).

Conclusions:

The results of the study showed prevalence of celiac disease of 0.5% in asymptomatic first grade school children. Children diagnosed with celiac disease require gluten-free diet and follow-up of gastroenterologist, nutritionist and school doctor. The results of the study will be used to raise the awareness and encourage more active search for celiac disease among asymptomatic school children.

Key messages:

- Recognition of celiac disease in asymptomatic children reduces risk of complications.
- Adequate diet for individuals with celiac disease should be ensured from kindergarten through school time.

The importance of relationships in adolescent risk behaviour prevention

Monique Lhussier

C Cooper[2], *M Lhussier*[1]
[1]Faculty of Health and Life Sciences, Northumbria University, Newcastle upon Tyne, UK
[2]North East Collaborative Outreach Programme, Newcastle University, Newcastle upon Tyne, UK
Contact: monique.lhussier@northumbria.ac.uk

Health risk behaviours are a key contributing factor to adolescent morbidity and mortality. Furthermore, evidence shows that health behaviours begun in adolescence can impact on wellbeing across the lifespan. Current evidence suggests it is advantageous to target multiple health risk behaviours simultaneously, however efficacy testing remains the key focal point for research, with few studies exploring common underlying causal and contextual factors which may contribute to the success or failure of a programme.

Methods:

This review used a customised realist approach, to explore how, why, for whom, and in what circumstances programmes are most successful in preventing multiple health risk behaviours in adolescents. The review synthesised evidence from published literature, along with qualitative data from stakeholders collected through focus groups with young people (n = 28) and school nurses (n = 22), and interviews with adolescent health and wellbeing practitioners (n = 8).

Findings: Across all the realist programme theories developed, the role of relationships was the most commonly occurring theme. This theme goes beyond the expected impact of the relationship between programme deliverers and recipients, and familial and peer attachments, also taking in to consideration the relationships between programme and school leaders and staff, support networks and collaborative relationships between staff, and wider social connectedness within the community. These in turn were impacted upon by wider contextual factors, such as family, community, culture, socioeconomic status, intersectionality, and health inequalities.

Conclusions:

These findings provide important insight in to understanding how, why, for whom, and in what circumstances multiple risk behaviour prevention programmes succeed or fail. Further to this they highlight key areas for consideration in the development of future adolescent public health interventions.

Key messages:

- Relationships built on trust and genuine care can improve adolescent risk behaviour prevention outcomes.
- Broader sociocultural context provide key explanations for variations in programme outcomes.

Identifying binge-eating disorders in obese young people living in vulnerable areas of Marseille

Severine Pinto

Contact: severine.duchamp@ap-hm.fr

Background:

While anxiety, depression and self-esteem have been identified as contributors to obesity, binge-eating disorder (BED) also requires attention to avoid worsening obesity. However, handling obese young people living in vulnerable neighbourhoods is rather difficult both in terms of psychosocial representations of obesity and the poor care offer. The objective of our exploratory research is to study the impact of a dedicated multidisciplinary management program on anxiety and depression of obese young adolescents presenting with, or not, a binge-eating disorder.

Methods:

Twelve patients (7 girls, 5 boys; mean age: 12.8 +/-1.3 years, range: 11-17) participated so far in this ongoing study. The mean body mass index was 36.5 +/- 7.2 (range: 27-53.4) for the group. They were all residents of vulnerable neighbourhoods of Marseille (France). They were evaluated at inclusion and 3 months after the 6-weeks program with the following self-questionnaires: Adolescent Binge Eating Disorder scale (ADO-BEDS), Hospital Anxiety Depression (HAD), 6-item Kutcher Adolescent Depression Scale (KADS-6), Self-esteem Measurement Scale for Adolescent (EMESA).

Results:

So far, only 3 patients were evaluated pre- and post-management. For two patients with ADO-BEDS scores at inclusion and post-management showing the presence of a BED, the KADS-6 and EMESA (general and physical appearance items) scores improved at 3 months. The remaining patient, without any depression signs at both inclusion and after 3 months, experienced a decreased self-esteem while a BED, not assessed at inclusion, was clearly revealed at 3 months. BMI did not change from pre- to post-management.

Conclusions:

Our clinical impression is that participating to the management program failed, at least for our first patients, to make them engage in a psychiatric/psychological therapy. Nevertheless, the program contributed to provide a motivating support system allowing them and their parents to become involved in their care.

Key messages:

- A multidisciplinary management program could potentially have a beneficial impact on depression and self-esteem in obese young adolescents presenting with a binge-eating disorder.
- The management program seemed to provide a motivating support system allowing obese young adolescents living in vulnerable neighbourhoods, and their parents, to become involved in their care.

Social deprivation and adverse perinatal outcomes in France: national study of preterm and SGA birth

Nolwenn Regnault

Y Barry[1], *A Gallay*[1], *N Regnault*[1]
[1]Non-Communicable Diseases and Trauma Division, Santé Publique France, Saint-Maurice, France
Contact: nolwenn.regnault@santepubliquefrance.fr

Introduction:

A slow but steady increase in preterm birth (PTB) rate has been reported in France in the last decades while decreasing in some European countries. Studies suggest PTB and small for gestational age (SGA) show a social gradient. Our objective was to determine whether this social gradient is changing in France over the study period.

Methods:

We selected all births records after 22 weeks of gestation in France between 2010 to 2017 (N = 6, 439, 355) in the French National Health Data System (SNDS). PTB was defined as birth before 37 completed weeks and SGA as birth weight below the 10th percentile according to the French intrauterine growth references curves. The SNDS includes an ecological social disadvantage index in quintiles (Q1:least deprived, Q5:most deprived). PTB and SGA rates were estimated in each deprivation quintile. Trends were quantified using a Poisson regression model.

Results:

The prevalence of PTB was 7.4% and SGA 11.9 % in 2017. French overseas regions (FOR) had the highest rates (7.2 vs. 10.9% and 11.5 vs. 18.0%, mainland France vs FOR respectively for PTB and SGA in 2017). Although we identified annual fluctuations, there was a significant average annual percentage change in prevalence of PTB and SGA respectively, +0.65% [IC95%:+0.1%; +1.2%; p = 0.03]; 0.66% [IC95%:+0.26%; +1.06%; p = 0, 01]. There was a marked but relatively stable social gradient over the study period. When combining all study years, PTB was more frequent among deprived women (Q5: 7.6% vs Q1: 6.8%) as well as SGA (Q5: 10.6% vs Q1: 12.1%).

Conclusions:

PTB and SGA prevalence trends are still increasing in France with regional disparities. Social deprivation remains a predictor of PTB and SGA.

Key messages:

- A persisting social gradient is observed in PTB and SGA in France.
- A better understanding of its mechanism will help designing interventions that will reduce social inequalities in health.

Environmental Health: Knowledge and Practice of Perinatal Health Professionals in Southern France

Claire Sunyach

C Sunyach[1], B Antonelli[2], S Tardieu[3], M Marcot[1], J Perrin[3,4], F Bretelle[1,2,5]

[1]Timone Hospital, Marseille, France

[3]Conception Hospital, Marseille, France

[4]Mediterranean Institute of Marine and Terrestrial Biodiversity and Ecology, Marseille, France

[5]Mediterranee Infection, Marseille, France

Contact: c.sunyach@gmail.com

Background:

The exposure of adults of reproductive age as well as of pregnant women and children to environmental contaminants is of particular concern, as it can impact fertility, in utero development, pregnancy outcomes and child health. Although worrying, this knowledge provides an opportunity to enforce interventions during these critical reproductive/developmental times, when they may have the greatest effect. Consequently, the World Health Organization (WHO) and international societies advocate including Environmental Health (EH) in perinatal care.

Objectives:

Our aim was to paint a picture of the current attitudes, representation, knowledge, and training expectations among Perinatal Health Professionals in south-eastern France.

Results:

In 2017, a cross-sectional study was performed in a large panel of perinatal HPs. Quantitative and qualitative information was collected via auto-questionnaire. Questionnaires were completed by 962 participants, mainly midwives (41.1%), physicians (25.6%) and nursery nurses (11%). Indoor/outdoor air quality and endocrine disruptors were the best-mastered topics, whereas electromagnetic fields and diet gave rise to unsure responses. Overall, perinatal HPs were ill-trained and -informed about the reproductive risks linked to daily environmental exposure. HPs reported scarce knowledge, fear of patient reaction and lack of solutions as the main barriers to providing information regarding EH to the public.

Conclusions:

In South-eastern France perinatal Health Professionals are eager to incorporate EH in their current practice. Our findings highlight the need to set up EH training programs focused on scientific knowledge and to provide simple messages and tips to help perinatal HPs deliver advice to populations to mitigate exposure to environmental toxicants.

Key messages:

- In South-eastern France perinatal Health Professionals are eager to incorporate EH in their current practice but ask for training.
- We are currently providing training programs combining practical sessions as well as basic and advanced scientific training adapted to the demand of medical and non-medical professional groups.

Surveillance of transient congenital hypothyroidism using the French newborn screening programme

Nolwenn Regnault

Contact: nolwenn.regnault@santepubliquefrance.fr

Introduction:

Congenital hypothyroidism (CH) is a condition of thyroid hormone deficiency present at birth. Untreated CH results in severe mental impairment. An increased incidence of CH has been reported in France and worldwide that could be explained by an increase in transient forms of CH (TCH). We aimed to estimate the proportion of transient eutopic gland based on the characteristics of children at birth.

Methods:

A probabilistic matching data from French CH neonatal screening program and French national health data system (SNDS) of children born between 2006 and 2012 (1, 763 with CH) allowed to linking 484 (68.8%) among 703 children with eutopic gland. Infants with six months or greater discontinuation of levothyroxine (LT4) treatment before the 31th December 2017 were classified transient CH. We used the Cox model to examine the predictors of TCH.

Results:

Among infants with eutopic gland, 52.9% were female, 14.9% were preterm and 14, 1 % had low birth weight, 11.8 % had a first degree family history of thyroid diseases, 48.1% of mild CH (TSH<50mU/L) at diagnosis and 30,0μg/j median dose of LT4 treatment. The probability of transient CH at five years of follow-up was 25.3% [IC95%:21.6% -29.4%] and 36.7% [31.7% -42.2%] after ten years. In a cox multivariable analysis, neonates with a TSH<50mU/L (adjusted Hazard Ratio = 4.1

[2.8-6.2]) and preterm 1.9 [1.1-3.4] had more risk to be transient.

Conclusions:

Prematurity and TSH level were predictors of transient CH. Additional analyses are ongoing to determine whether the occurrence of transient forms of TCH is increasing over the study period.

Key messages:

- Transient congenital hypothyroidism represent a significant part of HC at 10 years of follow-up.
- This finding has important implication on medical practices and should trigger research on the etiology of these transient forms.

Cost-effectiveness of mental health promotion and prevention for young people: a systematic review

Masja Schmidt

M Schmidt[1], A Werbrouck[2,3], N Verhaeghe[1,2], K Putman[1], S Simoens[3], L Annemans[2]

[2]Department of Public Health and Primary Care, Ghent University, Ghent, Belgium
[3]Department of Pharmaceutical and Pharmacological Sciences, KU Leuven, Leuven, Belgium
Contact: masja.schmidt@vub.be

Background:

Effective mental health promotion and mental disorder prevention interventions may reduce the impact that mental health problems have on young people's wellbeing. The objectives of this research were to summarize and assess health economic evaluations of mental health promotion and prevention for children and adolescents aged 6-18 years.

Methods:

Four electronic databases were searched for full health economic evaluations published between January 1, 2013 and October 31, 2018 that evaluated the cost-effectiveness of universal mental health promotion and primary mental disorder prevention interventions. Each study was subject to a systematic quality-appraisal.

Results:

Nine studies were included. Eight were carried out in the European Union, and eight evaluated school-based interventions. All evaluated interventions led to incremental costs compared to their comparators and most were associated with small increases in quality-adjusted life years. Four studies evaluated the cost-effectiveness of cognitive behavioural therapy-based interventions for the prevention of depression or anxiety, with mixed results. Cost-effectiveness estimates for mental health promotion and anti-bullying interventions were promising. Drivers of cost-effectiveness were implementation costs, intervention effectiveness, delivery mode and duration, baseline prevalence, and the perspective of the evaluation. The overall study quality was reasonable, though most studies only assessed short-term costs and effects.

Conclusions:

Few studies were found. This limits the possibility of drawing strong conclusions about cost-effectiveness. There is some evidence based on decision-analytic modelling that anti-bullying interventions represent value for money. There is a lack of studies that take into account long-term costs and effects.

Key messages:

- Based on the evidence, schools should be supported in the implementation of long-term anti-bullying programmes to improve young people's wellbeing.
- More research is needed on the long-term costs and effects of mental health promotion and prevention for children and adolescents.

VBAC or not VBAC? Improvement of performance and outcome indexes with the promotion of care safety

Sergio Parrocchia

G Nasi[1], S Parrocchia[2], AM Mastromatteo[1], A Triggiani[3], BA Miraglia[1], S Ferrazzani[4], U Moscato[5], P Metastasio[3], C Piscicelli[3], FA Distefano[3]

[5]Department of Public Health, Fondazione Policlinico A. Gemelli - IRCCS Catholic University of Rome, Rome, Italy
Contact: sergioparrocchia@yahoo.com

Background:

In a multidisciplinary approach to Quality Management System and humanization of care, we aimed at evaluating the characteristics that influence the request of women to carry out Vaginal Birth after Cesarean (VBAC).

Methods:

Skills have been improved, with the use of tests on dummies and case by case assessments. For the psychological-motivational study we have adopted: Informed consent, Semi-structured interview and Big Five Questionnaire. The women were recruited by both Gemelli and Cristo Re Hospital: the women following the counseling decided to undergo a second Caesarean Section (CS) (41, control group) and women who decided to complete a VBAC (22, experimental group).

Results:

The analysis of the data shows that the women of the VBAC group are in the average between 31-35 years (57%), 80% has an education = or > at the 3rd level and the choice of the VBAC was conditioned by the partner (64%). The women of the control group are in average > 35 years (51%), 60% have a higher average education and the influence on the choice is oriented by the gynecologist/obstetrician (64%). From the personality test a statistically significant difference emerges between the dimensions Energy and Mental Opening. Past experience influences the choice of the next birth: women who are inclined to a second CS considered the previous CS as a positive event (66%) while only 36% in the VBAC group; 64% of this was the recovery of the painful post-surgery and a certain type of difficulty in the care of the child, in breastfeeding, of having suffered from post-partum mood alterations, which is why they chose to undertake a Trial of Labor After Cesarean.

Conclusions:

The deeper knowledge of women as well as the preparation and safety of the same operators has shown that it is possible to perform a greater number of VBACs, with the sharing, participation and satisfaction of women and the entire team, leading to an improvement in outcomes and performance indexes.

Key messages:

- The promotion of care safety also improves the performance indexes through continuous training to the operators and the study of psychological aspects that lead to the choice to carry out a VBAC.
- Good Clinical Practice shown that it is possible to perform a greater number of VBACs, with the sharing, participation and satisfaction of women and the entire team.

Maternal admissions to Intensive Care Units in France: trends in rates, causes and severity

Nolwenn Regnault

Y Barry[1], C Deneux-Tharaux[2], M Saucedo[2], V Goulet[1], I Guseva-Canu[1,4], AA Chantry[2,3], N Regnault[1]

[1]Non-Communicable Diseases and Trauma Division, Santé Publique France, Saint-Maurice, France

[4]Institute for Work and Health (IST), University of Lausanne, University of Geneva, Epalinges-Lausanne, Lausane, Switzerland
Contact: nolwenn.regnault@santepubliquefrance.fr

Introduction:

Maternal intensive care unit admission (ICU) is an indicator of severe maternal morbidity. This study aimed to estimate rates of maternal ICU admission during or following pregnancy in

France, and to describe the characteristics of women admitted, the severity of their condition, associated diagnoses, regional disparities, and temporal trends between 2010 and 2014.

Methods:

Women hospitalised in France in ICU during pregnancy or up to 42 days after pregnancy between 2010 and 2014 were identified using the national hospital discharge database (PMSI-MCO). The Simplified Acute Physiology Score (SAPS II) was used to estimate the severity. Trends in incidence rates were quantified using percentages of average annual variation based on a Poisson regression model.

Results:

In total, 16,011 women were admitted to ICU, representing an overall rate of 3.97 ‰ deliveries. The average annual decrease in this rate between 2010 and 2014 was 1.7% (IC95%:-2, 00%; -1, 45%; $p < 0.0001$) on average per year. The SAPS II score increased significantly from 18.4 in 2010 to 21.5 in 2014. Obstetrical hemorrhage (39.8%) and hypertensive complications during pregnancy (24.8%) were the most common reasons for admission. Within mainland France, we found notable disparities in maternal ICU admission rates between regions, from lowest in Pays-de-la-Loire region (2.69‰) to highest in Ile-de-France (5.05‰).

Conclusions:

The rate of maternal ICU admission decreased from 2010 to 2014 in France, with a concomitant increase in case severity. Additional studies are needed to understand the territorial disparities identified in our study.

Key messages:

- The decreasing incidence of maternal ICU admission could be due to organisational changes with increased admission to intermediate care units.
- These changes have to be understood to accurately use maternal CU admission for maternal health surveillance.

A French network for prevention and reduction of reproductive risk in couples and pregnant women

Claire Sunyach

C Sunyach[1], *J Perrin*[2,3], *F Bretelle*[1,4,5], *C Paris*[6], *R Garlantezec*[6], *M Belacel*[7], *J-C Pairon*[7], *L Sentilhes*[8], *F Delva*[8], *P Brochard*[8]
[1]Timone Hospital, Marseille, France
[2]Conception Hospital, Marseille, France
[3]Mediterranean Institute of Marine and Terrestrial Biodiversity and Ecology, Marseille, France
[4]Mediterranean Network (PACA CORSE MONACO Perinatal Network), Marseille, France
[5]Mediterranee Infection, Marseille, France
[6]University Hospital, Rennes, France
[7]Intercomunal Center Hospital, Creteil, France
[8]University Hospital, Bordeaux, France
Contact: c.sunyach@gmail.com

Background:

Since 2013, several international (ASRM, FIGO, ACOG) and French (ANSES) learned societies and the French National Health and Environment Plan (2015-2019) urged to take into account exposures to environmental reprotoxic substances during standard care of infertile couples and pregnant women. However perinatal health professionals hardly incorporate this recommendation into practice.

Objectives:

To create a network of platforms to addressing the environmental aspects that can impact the pregnancy chances of infertile couples after ART and pregnancy outcomes.

We asked regional health authorities in France to provide funding for multidisciplinary hospital structures, in conjunction with clinical-biological reproductive health and gynecology-obstetric centers. Expertise, as well as information leaflets and risk detection tools have been shared.

Results:

Platforms of counselling and prevention have been set up in the University Hospitals of Bordeaux, Marseille, Rennes, Créteil and Paris Fernand-Widal. Infertile couples and pregnant women, referred by reproductive physicians, benefit from personalized management of their domestic/professional reprotoxic exposures by addictology/tobacco, dietetics, occupational health and environmental pathology professionals. The network organizes an annual scientific day and a common database of exposure is being set up.

Conclusions:

The PREVENIR (PREVENTION - ENVIRONMENT - Reproduction) network of platforms allows perinatal health professionals to refer their patients in order to optimize their chance of pregnancy through personalized and multidisciplinary care. The lifestyle changes initiated through this approach will also improve pregnancy outcomes and child health.

Key messages:

- A French network for the prevention and reduction of reproductive risk in infertile couples and pregnant women: the PREVENIR platforms (PREVENTION - ENVIRONMENT - Reproduction) is being established.
- Perinatal health professionals of multidisciplinary platforms engage into preventive actions to limit the exposure to environmental hazards during preconception and pregnancy.

Parental Education, Health Literacy and Children's Height in Adult Life

Alexi Gugushvili

E Jarosz[1], *A Gugushvili*[2]
[1]Institute of Education, University College London, London, UK
[2]Department of Social Policy and Intervention, University of Oxford, Oxford
Contact: alexi.gugushvili@spi.ox.ac.uk

Background:

Adult's body height has been positively associated with various health and social benefits. Studies have demonstrated that parental education is one of the key covariates of individual's health and height in both childhood and adulthood. However, another important covariate of child's health, parental functional literacy, has been largely overlooked in studies on height. The objective of this study was to analyse the associations between parents' education, their health literacy and children's adult body height.

Methods:

We used data for 17,331 men and 21,909 women from the 2016 wave of the nationally representative Life in Transition Survey (LITS) conducted in 34 countries in Southern and Eastern Europe, the Middle East, and Central Asia. Using ordinary least squares and Poisson regression models, we analysed the links between both mothers' and fathers' educational attainment, parental functional literacy - measured by the number of books in childhood homes - and individuals' height, while also taking into account other available individual and contextual explanations of height which occurred either before respondents' birth or during their childhood.

Results:

Our results demonstrate that mothers' educational attainment and parental functional literacy have strong independent associations with children's adult height. Sufficient literacy skills of the parent may have positive effect on children's growth even if parental education is low. These associations hold for both men and women and remain significant across time.

Conclusions:

This study offers a unique contribution by tracking the long-term trends in height and its socio-demographic and socio-economic explanations. Reported differences in individuals' adult height were linked with early childhood living conditions, specifically, with mothers' education and parental functional literacy.

Key messages:

- We track the long-term trends in height and its socio-demographic and socioe-conomic explanations.
- Regardless of the level of maternal education, parental functional literacy is a strong and consistent predictor of individuals' height.

First national results of the evaluation of the neonatal hearing loss screening programme in France

Nolwenn Regnault

A Doncarli[1], *H Tillaut*[1], *V Goulet*[1]
[1]Non Communicable Diseases and Trauma Direction, Santé Publique France, St Maurice, France
Contact: nolwenn.regnault@santepubliquefrance.fr

Background:

The French newborn hearing screening programme set up in 2014 aims to identify affected children as early as possible to allow appropriate care. Our goal was to evaluate the implementation of this programme at the national level.

Methods:

The programme consist in a screening using a test (T1) and a retest (T2) in the maternity hospital in all newborns. In some region, a delayed test (T3) is performed afterwards in children for whom it was not possible to confirm normal hearing. Children suspected of deafness subsequently enter the diagnosis phase. We defined evaluation indicators after stakeholders consultation. We developed a web application to collect aggregated data on live births. We estimated the rate of coverage, refusal, children suspected of hearing loss at the end of the screening phase and the prevalence of bilateral deafness.

Results:

In 2015, one year after the initiation of the programme, the coverage rate was already very high (88%) and even more so in 2016 (96%). Parental acceptance was very good (refusal: 0.1%). By the end of 2016, 19 out 27 regions had added a T3. The rate of suspicion of bilateral hearing loss was decreased by using a T3 (1.4% vs 0.9%). Bilateral deafness rate, estimated after a 2-years follow up, was 1.3‰ although it was estimated only on 51.5% of suspected children for whom diagnosis data had been transmitted.

Conclusions:

The objective of a 90% coverage set by the French ministry of health has been met after 2 years of operation of the program. T3 appears useful in relieving diagnostic structures from false positives. Our estimated prevalence of bilateral deafness could be more accurate if data collection was improved but is consistent with prevalence reported in North America.

Key messages:

- The universal newborn hearing screening program has been successfully set up in France in terms of coverage.
- Future work should focus on improving the collection of follow up data to better characterise diagnosed children.

Potential effective elements in combined lifestyle interventions for overweight children

Jenneke Saat

JJEH Saat[1,2], *GAJ Fransen*[1], *E Naumann*[2], *K van der Velden*[1], *WJJ Assendelft*[1]
[1]Academic Collaborative Centre AMPHI, Department of Primary Healthcare, Radboud University Medical Center, Nijmegen, Netherlands
[2]Research Group Nutrition and Health, HAN University of Applied Sciences, Nijmegen, Netherlands
Contact: jenneke.saat@radboudumc.nl

Background:

Combined Lifestyle Interventions (CLIs), offered in primary care, aim to prevent childhood overweight/obesity. Combined means the intervention focuses on optimalising nutrition behaviour, physical activity and mental health, provided by a multidisciplinary team. Although the effectiveness of CLIs is still not clear, CLIs are already implemented in daily practice in the Netherlands. These CLIs are not uniformly designed and have variations in protocols to suit the needs of their community. Due to the many different CLIs it is difficult to investigate their effectiveness. To be able to investigate effectiveness of GLIs, we first need to unravel the 'black boxes' of CLIs and identify their (potential) effective elements.

Methods:

First, we carried out a literature study on elements that may contribute to the effectiveness of a GLI (the so called potential elements). Next, we organized an online brainstorm session, where experts such as researchers and paramedics could add or specify potential elements. We made all elements measurable, with help of experts. These elements were incorporated into a tool to check presence of potential elements in CLIs. This tool was tested on reliability by comparing the results of four researchers who assessed protocols of six CLIs.

Results:

42 experts participated in the brainstorm session. The literature study and brainstorm session together resulted in 54 potential elements for CLIs for overweight/obese children, categorized in four themes: organization, content, role of parents and role of experts. For all six protocols, a minimum of 85% of the potential elements in the tool have been scored the same by the four assessors.

Conclusions:

We developed a reliable tool to determine potential effective elements in a CLI. In future studies, this tool can be used to identify specific elements that are effective in CLIs for overweight/obese children by comparing the tool with health effects of CLIs.

Key messages:

- We were able to develop a reliable instrument to better analyze the factors that contribute to positive health effects of combined lifestyle interventions for children with overweight or obesity.
- the developed tool with potential effective elements must be filled in for more CLIs, where after we can find corresponding elements in the most effective CLIs.

Women's experiences with labor companionship in public facilities in Arab countries

Tamar Kabakian-Khasholian

T Kabakian-Khasholian[1], *H Bashour*[2], *A El-Nemer*[3], *N Nameh*[1]
[1]Department of Health Promotion and Community Health, Faculty of Health Sciences, American University of Beirut, Beirut, Lebanon
[2]Damascus University, Damascus, Syria
[3]Mansoura University, Mansoura, Egypt
Contact: tk00@aub.edu.lb

Background:

Childbirth in the Arab region is characterized by overmedicalization and inequities in access to-and provision of care. Hospital practices do not provide choices for women and respond to the convenience of providers rather than women's needs. Provision of maternity care is reflective of existing social inequities which is manifested through mistreatment and disrespect of women within the health care system. One such example lies in the restriction of birth companions in public facilities in Arab countries despite being practiced in private settings and the strong evidence supporting its implementation globally.

Methods:

A phased mixed-methods implementation research study was undertaken in three public hospitals in Lebanon, Egypt and Syria with the aim of developing a tailored labor companionship model and evaluating its implementation. Data presented emanate from the qualitative component of the study. Semi-structured interviews were conducted with women giving birth (n = 59) and their labor companions (n = 57) in three facilities. Thematic analysis was used.

Results:

Beyond the introduction of the model into the system, women reported improvements in dimensions of respectful maternity care. Changes made in shared labor rooms improved women's privacy. The presence of labor companions improved communication between health care providers, women and their families. Women reported feeling "dignified" and "strong" in the presence of companions. There was a "feedback loop" from the facility to the community with word spreading about labor companionship "just like in private hospitals".

Conclusions:

The labor companionship model improved equitable access to dignified and respectful maternity care through better rapport between women and health care providers, preservation of women's privacy and having access to birth companion of choice. The provision of evidence-based care has potential implications on women's experiences with the health care system.

Key messages:

- This labor companionship model ensured positive experiences for women giving birth in public facilities in Arab countries.
- Women perceived the model as type of care that reduces differential treatment based on social status and enhances respectful maternity care.

Trends in physical activity and overweight among adolescents and their parents in Russian population

Diana Denisova

D Denisova[1], *L Scherbakova*[1], *I Berezovikova*[1]
[1]Lab of Preventive Medicine, Research Institute of Internal and Preventive Medicine, Novosibirsk, Russia
Contact: denisovadiana@gmail.com

Background:

Unhealthy lifestyle, including physical inactivity and overweight, typically begins in adolescence. Familial aggregation of the factors aggravates the predictive risk. During the 1990s Russian population has been exposed to major political, economic and social changes.

Methods:

Seven cross-sectional surveys of representative samples of school children aged 14-18 in 1989-2019 were carried out in Novosibirsk. Total sample was 4677 (45% males). To define overweight in adolescents the sex- and age-specific BMI cut-offs of the IOTF were used. Information about parents physical activity (<150 min/week), height and weight was obtained by mail questionnaire. Parents overweight registered if $BMI \geq 25$.

Results:

Levels of low physical activity in adolescents were stably high during all the period in boys (49-55%) and girls (83-73%) with a rising trend in recent years. In 2009 average amounts of weekly screen time were 18 hours in boys and 15 hours in girls, In 2019 - 35 and 33 hours respectively. Their parents had low levels of physical activity: 2,5 hrs/w in men and 1,5 hrs/w in women without any trends. The prevalence of overweight among adolescents during the 30-year period showed U-curve characteristic with significant decreasing (4,0%) at the end of 90s and rising since 2003 particularly in boys (17.6% in 2019, $P < 0{,}01$). Overweight prevalence among parents was high: from 25% in 1989 to 38% in 2019 ($P < 0{,}05$) and from 32% in 1989 to 28% in 2019 among fathers and mothers respectively. Familial associations between parents and children were found for overweight but not for levels of physical activity.

Conclusions:

Levels of physical activity in Siberian adolescents and their parents were low during 30-year period. Trends in the prevalence of overweight in this groups were differed. Familial aggregation of overweight indicates necessity of preventive actions at a family level.

Supported by grant No. 19-013-00800 of RFBR.

Key messages:

- Levels of physical activity in Siberian adolescents and their parents were low during 30-year period.
- Trends in the prevalence of overweight in adolescents and their parents were differed: the shaped curve in children and linear - in parents. However familial associations of overweight were found.

School bullying among Tunisian adolescents: prevalence and psychosocial outcomes

Jihene Sahli

J Sahli[1], *M Limam*[1], *M Mellouli*[1], *M El Ghardallou*[1], *T Ajmi*[1], *C Zedini*[1], *A Mtiraoui*[1]
[1]Department of Familial and Community Medicine, University of Sousse, Faculty of Medicine of Sousse, Research Laboratory ''LR12ES03'', Sousse, Tunisia
Contact: dr-jihene19@hotmail.com

Background:

Bullying is a serious public health concern affecting the emotional well-being of pupils. We conducted this study to examine the prevalence of bullying, its psychosocial associated factors and the perceived involvement of parents, teachers, and classmates to counteract this behavior.

Methods:

This is a cross-sectional study conducted in 2015 among a representative sample of pupils enrolled in 14 colleges in Sousse using the revised Olweus Bully/Victim Questionnaire.

Results:

We included 1584 students aged between 11 and 15 years. The prevalence of bullying and victimization was 16.0% [95% CI: 14.2%, 17.8%] and 11.3% [95% CI: 9.7%, 12.9%] respectively. Four groups of students were identified, 11.7% were classified as pure victims, 7.8% as pure bullies, 3.2% as bully-victims and 75.5% as bystanders. Compared to other groups, the bully-victims were less likely to report a feeling of empathy (38.3%, $p < 10\text{-}3$) and liking school (30.0%, $p < 10\text{-}3$). They were more likely to be aggressive (56.2%, $p < 10\text{-}3$) and disintegrated in the class (30.6%, $p = 0.002$). Among the victims, 11.1% reported that their parents contacted the school several times to stop their victimization. The majority of the middle school students perceived that their classmates (54.1%) and teachers (39.5%) did nothing to counteract the bullying behavior.

Conclusions:

The school institution is expected to be for pupils a highly meaningful space for social, emotional and academic development. Parents, teachers and students should learn effective ways to handle the bullying problem since it has been emphasized that the most effective programs are comprehensive targeting students, schools, families, and the community.

Key messages:

- This is the first study conducted in Tunisia to highlight the extent of school bullying.
- Our findings can help to raise awareness of parents, school staff and policy makers about bullying.

Parents' evaluation of early home visit by midwife

Ragnhild Sollesnes

R Sollesnes[1], *A B V Nilsen*[1], *E Langeland*[1]
[1]Western Norway University of Applied Sciences, Bergen, Norway
Contact: rso@hvl.no

Background:

The Norwegian guidelines for postnatal care strongly recommend that families are offered home visit by a midwife within the first week after early discharge from maternity clinic, in addition to home visit by health visitor 7-10 days after delivery. Due to lack of midwifery resources out of hospital, Bergen municipality has started a project where selected groups such as first time mothers, minority families and women who during pregnancy are defined as being in need of extra follow up, receive a home visit by their antenatal midwives. The main purpose of the study is to explore user satisfaction with the home visit by the midwife, and the parents' experience of security and coping the first week after the delivery.

Methods:

The design is a mixed method design including a clinical controlled trial. In addition to questions about the home visit, Parents' Postnatal Sense of Security is used to measure safety, and by The Orientation to Life Questionnaire, coping as a Sense of Coherence is measured. The trial includes an intervention group who receive home visit by midwife, and a control group who met the inclusion criteria, but of different reasons do not receive home visit by midwife. The data collection started in November 2018 and is in progress.

Results:

Preliminary results shows that the families consider home visit by midwife as useful, and as a good support the first week after delivery. Results from comparing the two groups regarding Sense of Security and Sense of Coherence will be presented.

Conclusions:

Implications for better postpartum care will be presented.

Key messages:

- Investigate parents' satisfaction with postpartum care at home, and 'sense of security' and 'coping as a sense of coherence'.
- Contribute with suggestions for how to improve the postnatal care in a health promoting perspective.

Analysis of coordinating capacities in schools of grades 10 and 11 in a public school of Bogotá

Natalia Stephany Morales Eraso

N Morales Eraso[1], M Riveros Medina[1,3], A Gutiérrez Galvis[1], J Alvarado Melo[1,4], O Rubiano Espinosa[1,2], E Acosta Rodríguez[1], C Melo Moreno[1]
[1]Science Education Faculty, Libre University, Bogota, Colombia
[2]Recreation, Sports and Recreation Institute, Bogota, Colombia
[3]Physiotherapy, Manuela Beltrán University, Bogota, Colombia
[4]Science Education Faculty, Minuto de Dios University, Bogota, Colombia
Contact: natimorales05@icloud.com

Studies that address the problem of excess weight and inactive behaviors such as television and video games in children and adolescents have focused on chronic noncommunicable diseases, with few studies about the effects of sedentary lifestyle on coordination capacities (balance, precision and movement capacity).

The objective of the study is to analyze the coordinative capacities in school children of grades 10 and 11 in a public school in Bogotá. This analytical cross-sectional study was conducted on 63 schoolchildren (30 men and 33 women) with an average age of 16.24 ± 0.689. The motor quotient was evaluated by means of the KTK test with the authorization of the institutional ethics committee, assent signature and informed consent. Descriptive statistics were obtained (mean SD frequencies, percentages). Data were tested using Kolmogorov-Smirnov test and independent t-test was applied to measure the significant difference among the variables. P-value less than 0.05 was considered a significant difference.

The motor quotient showed the following qualifications: symptomatic 11.1% (n = 7), normal 58.7% (n = 37) and good 30.2% (n = 19). Statistically significant differences ($p < 0,05$) were found in the motor quotient between boys (37,048) and girls (34,374), with girls being mainly in the symptomatic category. It can be concluded that girls need to increase motor experiences to improve their coordinative abilities. The importance of this study consisted in the possibility of identifying the effects of sedentarism on coordination capacities, as well as the impact produced by the current government by reducing hours of physical education in schools, leading to an increase in sedentarism. For this reason, it is essential to develop research aimed at stimulating coordination capacities in schoolchildren as a strategy to reduce public health problems.

Key messages:

- For this reason, it is essential to develop research aimed at stimulating coordination capacities in schoolchildren as a strategy to reduce public health problems.
- Promotion of public policy as a Determining factor in the reduction of sedentarism in children, through Strategies that include assessment of Coordinating Capacities of schoolchildren.

DF Chronic diseases

Association between leisure-time physical activity and the risk of chronic diseases

Audrius Dedele

A Dedele[1], A Miskinyte[1]
[1]Department of Environmental Sciences, Vytautas Magnus University, Kaunas, Lithuania
Contact: audrius.dedele@vdu.lt

Background:

According to the World Health Organization, non-communicable diseases or chronic diseases, account for 71 percent of all deaths globally, affecting individuals of all age groups and countries. Epidemiological studies have shown an association between a lack of physical activity (PA) and the risk of raised blood pressure, increased body mass index and obesity that can lead to chronic diseases.

Methods:

The aim of the study was to assess the relationship between leisure-time PA and the risk of chronic diseases among adult population. We conducted a cross-sectional study of 470 men and 641 women who participated in "The Impact of Sustainable Mobility, Physical Activity and Environmental Factors on Urban Population Health Study (ISMA)" in Lithuania. Leisure-time PA was self-reported and divided into three levels: low, moderate and high. Logistic regression was used to estimate adjusted odds ratios (ORs) of chronic diseases according to leisure-time PA.

Results:

More than half (55%) of the study population engaged in a moderate intensity PA and 12% of participants engaged in a high intensity leisure-time PA. Men 1.6 times more often than women reported engaging in a high intensity PA in leisure time (p = 0.004). Adults who engaged in low intensity leisure-time PA had almost 3 times (OR = 2.91; 95% confidence interval (CI) 1.62-5.24) higher risk of chronic diseases, whereas those adults who reported moderate intensity leisure-time PA had an OR of 1.63 (95% CI 0.92-2.87) compared to individuals who engaged in a high-level PA.

Conclusions:

Our findings suggest that high levels of leisure-time PA could reduce the risk of chronic diseases and this effect was significantly stronger in men.

Key messages:

- Global decline in PA is related to inaction during leisure time and sedentary behaviour at work and at home that has a major health impact worldwide.
- High levels of leisure-time PA are important factor for chronic disease prevention.

Using 'White Flags' to categorize socio-cultural aspects in chronic pain

Claudia Winkelmann

C Winkelmann[1], TU Schreiber[2]
[1]University, Alice Salomon Hochschule Berlin, Berlin, Germany
[2]Stv. Chefarzt Muskuloskelettale Rehabilitation, Reha Rheinfelden, Rheinfelden, Switzerland
Contact: winkelmann@ash-berlin.eu

Issue:

Persistent chronic pain is a major medical and health economic problem. To assess the individual pain situation, the classification of various factors (flags) has been established.

Description of the problem:

Structural biomechanical factors are classified as ''red flags''. Psychological or behavioral factors are summarized as ''yellow flags'', psychiatric and mental illness as ''orange flags''. Both last flags are important for planning adequate therapies or rehabilitation, as well as for decisions to prognoses and tailored reintegration programs. An extension of the flag model was achieved by naming personal factors at workplace as ''blue flags'', and ''black flags'', if there is a restriction for returning to work. All these groups do not consider other important reasons for unsuccessful rehabilitation or failed reintegration.

Results:

In these cases, often described as 'therapy-refractory', clients often exhibit a special subjective understanding of illness that reacts neither to psychological interventions nor to behavioral therapies. These include individual beliefs based, for example, on cultural socialization, religious education, or spiritual experiences. Since such individual mental illnesses are culturally ideologically or religiously justified, they should be classified in a separate group called 'white flags'.

Lessons:

The advantages of categorizing sociocultural aspects separately from other flag classifications are

- avoidance of unnecessary therapies, including surgery,
- prevention of iatrogenisation,
- prevention of legal disputes.

It is important to realize that only health restrictions for insurance benefits can be taken into account and that individual socio-cultural circumstances or health convictions are not evaluated.

Main messages: A classification of 'white flags' could contribute to a better classification of pain which are not accessible to various therapies and reduce reservations and misunderstandings by intercultural communication approaches.

Key messages:

- For medical professions it is important to recognize, that only health inabilities are taken into account for insurance compensation and not individual socio-cultural circumstances or health beliefs.
- In Future classifying 'white flags' could help to properly assess persistent pain conditions.

Teaching Program for laymen and experts for neighborhood-based offers to elderly people living alone

Claudia Winkelmann

C Winkelmann[1], *L Kasprick*[2]
[1]Social Sciences, Alice Salomon Hochschule Berlin, Berlin, Germany
[2]Projects, Gerinet, Leipzig, Germany
Contact: winkelmann@ash-berlin.eu

Background:

For multimorbid very old people who are living alone, care networks are needed to ensure continuous and coordinated care across the sectors.

Objectives:

The GeriNeTrainer (trainer in a geriatric network) is intended to preserve the day-to-day competences of elderly and to reduce the prevailing regional lack of help. Which content and structural aspects must include an educational concept that is aimed equally at laymen and experts (e g physiotherapists, nurses) and can be implemented sustainably? The competence profile was developed by an interprofessional staff of experts. According to the literature review, they rated the CanMeds role concept as the most relevant and suitable framework with regard to the holistic approach to care. Therefore, the teaching curriculum was developed based on this.

Results:

Depending on the level of knowledge, interested laymen or experts enter the evident curriculum. The team of lecturers consists of physiotherapists, social workers, physicians, sports scientists, psychologists and speech therapists. As teaching and learning methods were defined: lectures, seminars, exercises, caseworks as well as compulsory homeworking in best practice facilities. The interprofessional imparting of knowledge as well as the exchange of experience between the individual occupational groups as well as the methodical inclusion of the perspective of laymen were evaluated as particularly beneficial and innovative. For sustainability, the certified graduates are supervised. Observation, a case study based on this, an electronic platform (Moodle) and annual conferences and symposia enable regular and practice-oriented communication and quality assurance in the sense of the continuous improvement process.

Conclusions:

The graduates are connecting patient home with the health facilities. Increased professional, social and emotional competence in the quarter have positive effects of elderly people who are living alone.

Key messages:

- Valuable is the educational concept by conveying knowledge and exchange of experience of individual specialist groups as well as the lay perspective.
- Laymen and experts are learning together, their different perspectives are very helpful for the elderly.

Beyond the diabetes epidemic – a public health challenge

Sarah Cuschieri

S Cuschieri[1], *J Mamo*[2]
[1]Anatomy, University of Malta, Msida, Malta
[2]Public Health, University of Malta, Msida, Malta
Contact: sarah.cuschieri@gmail.com

Introduction:

Various factors pertain to the development of type 2 diabetes (T2DM). While exploring the risk factors and links to T2DM at a population level, certain unexpected relationships were identified in a cross-sectional study representative of adults in Malta (2014-6).

Methods:

A health examination study was conducted among a representative sample of adults in Malta (18-70 years). Validated medical data was collected for fasting glucose (FBG) and lipid profiles. Self-reported Diabetes (T2DM) and a fasting glucose level(FBG) >7mmol/L were labelled as T2DM. Regression analysis explored T2DM and components of the lipid profile while adjusting for confounding factors (age, gender, residing locality, education level, employment status, use of statins). Separate analysis compared non-diabetic and metabolically healthy sub-populations as a reference to T2DM population respectively.

Results:

A negative association was found between an increase in LDL-C (OR: 0.76 CI 95% 0.65 - 0.89, p = <0.01) and a diagnosis of T2DM when the non-diabetic sub-population was the reference category. A negative association was also present for total cholesterol (OR: 0.79 CI 95% 0.69 - 0.91, p = <0.01). On the contrary, a positive relationship with T2DM was present for both parameters (LDL-C OR: 4.15 CI 95%: 2.79 - 6.17, p = <0.01 and Total cholesterol OR: 2.45 CI 95%: 1.84 - 3.33, p = <0.01) when the metabolic healthy sub-population was the reference category. Similar results were present after adjusting for confounders.

Conclusions:

Individuals without an established diagnosis of T2DM but with a biochemical and/or anthropometric abnormality are still at metabolic risk. Hence, preventive policies targeting metabolically at-risk persons at the community level need to be explored in order to target the health inequalities gap.

Key messages:

- Health inequalities are present in individuals with normoglycemia but with biochemical and/or anthropometric abnormality.
- Preventive policies need to target metabolically unhealthy population irrelevant of their glucose status.

Lifestyle related risk factors of coronary artery disease patients in Nepal

Pramila Gaudel

P Gaudel[1], *M Kaunonen*[1], *S Neupane*[1], *K Joronen*[1], *AM Koivisto*[1], *A Rantanen*[1]
[1]Health Sciences, University of Tampere, Tampere, Finland
Contact: pramila.gaudel@tuni.fi

Background:

Coronary Artery Disease (CAD) is a leading cause of morbidity and mortality and serious health problem worldwide. It is important to observe lifestyle related risk factors in patients with CAD for effective planning and implementation of secondary prevention strategies. The aim of this study is to describe the prevalence of lifestyle related risk factor habits among the patients with CAD.

Methods:

A cross-sectional study was conducted among CAD patients in a tertiary care national heart center in Kathmandu, Nepal. Six lifestyle related factors (dietary habit, smoking, alcohol consumption, stress, physical activity and adherence to medication) and Body Mass Index were used as the risk factors of CAD in this study. Individual face-to-face structured interview was conducted using culturally validated standard instruments. The descriptive characteristics were presented as frequencies and percentages for categorical variables and as mean ± standard deviation (SD) or median and interquartile range (IQR) otherwise.

Results:

In total study population, the mean age of the patients was 59.9 years and 76% were male. Patients having any three risk factors out of seven were the most common (36%) followed by two risk factors (25%) and four risk factors (22%). About 32% of study population were current smokers, whereas 29% were former smokers. Likewise, 31% of the total were physically inactive. Majority of the patients 95% had perceived moderate stress.

Conclusions:

The prevalence of lifestyle related risk factors is high among CAD patients in study population. Combination of any three lifestyle related risk factors were the most common among patients. Therefore, studies focusing on lifestyle risk factor modification intervention on particular groups is recommended.

Key messages:

- Need to improve awareness about lifestyle related risk factors among CAD patients.
- Highlight the importance of lifestyle counselling.

Positive health as a new concept for physiotherapy in the Netherlands?

Cindy De Bot

CMA De Bot[1], *C Boemaars*[2], *JAJ Dierx*[1]
[1]Living in Motion Research group, Avans University of Applied Sciences, Breda, Netherlands
[2]Bachelor of Physiotherapy, Avans University of Applied Sciences, Breda, Netherlands
Contact: cma.debot@avans.nl

Background:

The current WHO definition of health seems to no longer meet the changes in the current Dutch health system. An alternative approach which puts emphasis on health, not disease, is Positive Health. This focus shifts the emphasis on improving resilience and well-being rather than the perspective on what is lacking in health. In 2014, this new definition of Positive health was included in the professional profile 'physiotherapist' of the Royal Dutch Association for Physiotherapy. This study examines the attitude of physiotherapists to Positive Health and to what extent they experience this concept in their current working practice.

Methods:

A mixed method study was used, with a quantitative and qualitative method. A survey was completed by 276 physiotherapists and 7 semi-structured interviews were conducted among physiotherapists.

Results:

Positive health was considered positive by 68% of the physiotherapists that health is seen as a dynamic concept rather than static, and 60.5% consider it important that the emphasis is on self-regulation. However, physiotherapists wonder if all patients have the ability to self-manage skills. The qualitative analysis shows that all therapists find the new definition positive and that it covers all aspects of health.

Conclusions:

In general, physiotherapists are positive about the definition of positive health. Positive health can help physiotherapists in their work with clients and other professionals because of the multidisciplinary approach.

Key messages:

- Positive health can help physiotherapists to promote health in their clients.
- Positive health can stimulate cooperation between physiotherapists and client to increase self-management.

Unsatisfactory effectiveness of preventive programs for oncogynecological diseases in Bulgaria

Stela Georgieva

S Georgieva[1], *P Stefanova*[1], *M Kamburova*[1]
[1]Medical University of Pleven, Pleven, Bulgaria
Contact: georgieva_sl@yahoo.com

Background:

Incidence rate and mortality of breast cancer and cancer of the cervix uteri in Bulgaria are higher in comparison with most countries of European Union (EU). Moreover, during the last three decades they have been increasing, even doubled for cervix cancer, although in developed countries there are proven effective prevention programs. The aim of the study is to explore how these programs are being implemented in Bulgaria and what caused their unsatisfactory results.

Methods:

Data were collected by documents review and direct individual self-administered questionnaire among 186 women aged 30-69 concerning types and regularity of preventive activities.

Results:

National Health Insurance Fund in Bulgaria defines as mandatory and finances a regular check-up annually for health insured people over 18 years of age. Mammography, as a screening of a breast cancer, was included in regular check-up package from the year 2011, once at every two years, for women aged 50-69. Papanicolau test for cancer of the cervix uteri wasn't provided in the preventive package until the year 2017 when it was included only for women who complete 30 years of age in the current calendar year with intended regularity once at every two years. Women from other age groups currently are not covered with preventive examination for cervical cancer or they should pay for it which restricts accessibility and affordability of prevention activities. Study results indicates that every fifth of the investigated women have never had a prophylactic examination for breast cancer and cervical cancer. In addition, 69.4% of those who have such examination did not comply with the recommended regularity.

Conclusions:

Screening programs against breast cancer and cancer of the cervix uteri are consistent with the recommendations of the oncology research societies but they being applied relatively soon in Bulgaria and some age groups are out of their coverage which decreases their effectiveness.

Key messages:

- Incidence rate and mortality of breast cancer and cancer of the cervix uteri in Bulgaria are higher than in most countries of European Union although there are proven effective prevention programs.
- Screening programs against breast cancer and cervical cancer are not effective because of their low accessibility and

affordability and because they don't comply with the recommended regularity.

Type2 diabetes:changing patterns of use of antidiabetic drugs 8 years after starting treatment(snds)

Anne-Sophie Aguadé

AS Aguadé[1], C Gastaldi-Ménager[1], D Karsenty[1], P Fontaine[2], A Fagot-Campagna[1]
[1]CNAM, Paris, France
[2]CHU, Lille, France
Contact: anne-sophie.aguade@assurance-maladie.fr

Objective:

To describe the changing patterns in the use of the various classes of antidiabetic drugs in a cohort of patients newly treated for diabetes from 2008 to 2015 on the basis of comprehensive health insurance data.

Methods:

General scheme beneficiaries 45 years and older were identified in the French National Health Data System (SNDS) as newly treated when antidiabetic drugs were dispensed on at least 3 different dates in 2008 and at least once during the last 4 months of 2008, but were dispensed less than 3 times in 2006-2007. Treatment regimens for the last 4 months of each year were defined for this cohort.

Results:

158,000 people (53% men, mean age 62 years) initiated antidiabetic drug therapy in 2008: monotherapy (without insulin): 74%, dual therapy: 17%, treatment with 3 or more drugs: 3%, and insulin therapy: 7%. The proportion of patients taking monotherapy decreased by 13 percentage points during the second year and only 32% of the cohort was treated by monotherapy 8 years after starting treatment. The proportions of patients taking dual therapy increased by 4 percentage points (21% in 2015), triple therapy increased by 8 percentage points (11%), a combination of insulin+other antidiabetics increased by 4 percentage points (7%) and insulin alone remained stable (4%). At the last quarter of 2015, 12% of patients did not receive any antidiabetic drugs and 13% had died. The creation of a cohort of diabetic patients newly treated in 2013 demonstrated changing prescribing practices: a lower proportion of monotherapy in the first year of treatment, but a growing use of metformin.

Conclusions:

Treatment was intensified during the first 8 years for one half of the cohort. The maximal dosage of Metformin is not used before introducing a second antidiabetic in 1 case in 2. Insufficient use of Metformin, in general and in terms of dosage, was observed, although this use is improving.

Key messages:

- Initiation of antidiabetic drug therapy in people 45 years and older consisted of monotherapy in 3/4 of cases in 2008.
- Insufficient use of Metformin, in general and in terms of dosage, was observed, although this use is improving.

Dynamics of the occupational respiratory diseases in Bulgaria in the period 2009-2016

Karolina Lyubomirova

N Tzacheva[1], M Tabanska-Petkova[1], K Lyubomirova[1]
[1]Faculty of Public Health, Medical University - Sofia, Sofia, Bulgaria
Contact: carol_lub@abv.bg

Background:

The number of occupational respiratory diseases has declined in recent years in Bulgaria. This is the result of technological advance, mechanization and automation of the processes generating high levels of dust in the work environment; adequate ventilation; personal protective equipment and, last but not least, the training of workers on preventive approaches.

Methods:

The aim of the study is to find out the trends of registered occupational respiratory diseases in Bulgaria in 2009-2016, according to official statistics. Analytical and statistical methods were used.

Results:

In 2016, the number of occupational diseases (n = 33), registered in Bulgaria decreased by 71.55% compared to 2009 (n = 116). In 2009, the relative share of silicosis from respiratory occupational diseases was 47.54% (n = 29), while in 2016 it grew to 64.29% (n = 9). Its share is also increasing as part of all occupational diseases in Bulgaria from 25% in 2009 to 27,27% in 2016. The registered cases of chronic rhinitis, nasopharyngitis and pharyngitis for the whole period are only 2, of professional asthma - 3; of chronic bronchitis - 5, less than cases of asbestosis - 9. In 2009, there were five reported cases of talcosis and the total number of cases of siderosis was 23 for the period of eight years. There are 4 cases of other pneumoconiosis and 2 of pneumoconiosis associated with tuberculosis, as well as 10 cases of toxic pulmonary fibrosis during the whole period.

Conclusions:

It is worth noting the small number of occupational respiratory diseases that could be caused by other factors not necessarily related to the work environment, such as chronic bronchitis and asthma, although they are significantly more frequent than those mandatory caused by occupational hazards such as silicosis, asbestosis and toxic pulmonary fibrosis. This means that a significant proportion of these cases are counted as common chronic non-communicable diseases with significant negative social consequences.

Key messages:

- The registered occupational respiratory diseases decrease, but the relative share of those with strictly professional etiology, such as silicosis, is growing.
- A significant proportion of occupational respiratory diseases are reported as chronic non-communicable diseases.

Prevention of chronic diseases in family medicine in Croatia

Maja Maric-Bajs

M Maric-Bajs[1], A Puljak[1], M Polić Vižintin[1]
[1]Department of Public Health, Andrija Stampar Teaching Institute of Public Health, Zagreb, Croatia
Contact: maja.maric-bajs@stampar.hr

Background:

Inappropriate habits and behaviour patterns are risk factors for most chronic non-communicable diseases. Prevention and education are one of the continuous tasks of public health professionals. Primary preventive care requires an active approach from the health professionals.

Methods:

This program includes preventive examination and certain laboratory tests persons older than 55 who did not visit their family doctor at least two years. 721 persons were examined and interviewed from 2014 to 2018. The paper shows analytic results expressed in percentages of the prevalence and 95% confidence interval (CI).

Results:

A total of 721 patients were included. Sex ratio male:female was 0.47. The age (mean) was 61.4 years [standard deviation (SD) = 9.1]. Up to three alcoholic drinks per week consumed 22.1% respondents (37.1% male and 11.9% female). There were 24.1% smokers and 14.6% former smokers. Overweight (BMI 25-30) were 44.4% male and 36.3% female. Obese (BMI>30) were 27.6% male and 30.3% female. Digitorectal examination was performed in 582 persons and detected pathological phenomena in 10.3% female and 19.4% male. Hypertension was found in 14.9% male and 18.2% female. Isolated systolic hypertension was found in 19.8% male and 16.7% female, and isolated diastolic hypertension in 3.9% male and 3.5% female. Suspicion on one or more newly diagnosed disease was placed in 55.9% (95% CI 52.3-59.5) respondents. In total, there was a suspicion of 696 newly diagnosed diseases. Newly diagnosed diseases were disorders of lipoprotein metabolism (n = 156, 21.6%), followed by hypertension (n = 69, 9.6%), obesity (n = 52, 7.2%) and independent of insulin diabetes (n = 51, 7,1%). 53 persons [7,4% (95% CI 5,4-9,3)] had suspected neoplasm and they were immediately referred for further diagnostic evaluation.

Conclusions:

The public health significance of such programs with active approach and detecting malignant state as early as possible is extremely important.

Key messages:

- Primary preventive care requires an active approach from the health professionals.
- Detecting chronic non-communicable diseases in earlier phase is important and confirms the public health significance of prevention programs.

Mortality trends for multiple sclerosis in Italy

Francesco Gori

F Gori[1], L Kundisova[1], D Bezzini[2], A Martini[3], L Giovannetti[3], E Chellini[3], N Nante[1,2], G Messina[1,2], M A Battaglia[1]

[1]Department of Molecular and Developmental Medicine, Post-graduate School of Public Health, University of Siena, Siena, Italy
[2]Life Science Department, University of Siena, Siena, Italy
[3]Institute for Study, Prevention and Cancer Network, Firenze, Italy
Contact: francescogori24@gmail.com

Background:

Multiple sclerosis (MS) is the immune-mediated inflammatory disease affecting myelinated axons of the central nervous system with enormous socio-economic impact. The aim of this study was to analyze mortality trends for MS in Italy.

Methods:

The mortality data relative to period 1980-2015 were provided by Italian Institute of Statistics, data were aggregated in 5 intervals (1980-1986; 1987-1993; 1994-2000; 2001-2008; 2008-2015). The Age-Standardized mortality Rates (SR) with respective 95% confidence intervals (95%CI) were calculated (using the European standard 2013) in order to evaluate the mortality trends (in confrontation to the initial period) and Standardized Mortality Ratios (SMR), in order to confront mortality in 5 major geographic areas: North-East (NE), North-West (NW), Central Italy (CI), South Italy (SI) and Islands (I).

Results:

During the study period 4959 deaths for males and 7433 for females were observed. The SRs were significantly higher for females (0.71;95%CI:0.70-0.73 vs. 0.56; 95%CI:0.54-0.57).

Significantly higher SMR were observed for both sexes in I (M:123.3 vs F:112.7), for females also in NE (106.5) and NW (115.8). Significantly lower SMR for both sexes were observed in SI (M:88.8; F:71.4) and for males in CI (90.9).

The observed SRs during the five intervals for males were: 0.65(95%CI 0.60-0.69); 0.52 (95%CI 0.49-0.56); 0.46 (95%CI 0.43-0.49); 0.53 (95%CI 0.49-0.56); 0.59 (95%CI 0.56-0.62); and for females: 0.69 (0.65-0.73); 0.69 (0.65-0.73); 0.61 (0.58-0.65); 0.68 (0.65-0.72); 0.81(0.77-0.84); respectively. An initial decrease of SRs was observed for males until 2001-2007 in confrontation to the initial period ($p < 0.05$). For females significant increase of SRs was observed in 2008-2015 ($p < 0.05$).

Conclusions:

An increase of mortality for MS, observed for females, especially after 2000 may reflect the raising prevalence of MS in Italy. Important geographical differences were observed for five main areas.

Key messages:

- During the study period an increase of mortality for MS was observed for females.
- Important differences were observed between five main Italian geographic areas.

Maternal perceptions of paediatric cancer and diabetes in Cameroon

André Wamba

A Wamba[1], M Matchika Mégaptché[2], J-P Mambou Nouemssi[3], P Koki Ndombo[4], A-H Pondy Ongotsoyi[5]

[1]Departement of Education, Wamba, Yaoundé, Cameroon
[2]Department of Sociology, Matchika Mégaptché, Yaoundé, Cameroon
[3]University Lumière Lyon 2, Mambou Nouemssi, Lyon, France
[4]Department of paediatric, Koki Ndombo, Yaoundé, Cameroon
[5]Mother Child Center of the Chantal Biya Foundation, Pondy Ongotsoyi, Yaoundé, Cameroon
Contact: wandre71@yahoo.fr

Background:

Maternal perceptions of paediatric cancer and diabetes are still poorly studied in Cameroon, while they are considered as an inevitable part of the chronic diseases. Little is known to what maternal representations of paediatric cancer or diabetes refer to. Their contents remain unknown; and they are rarely taken into account in training programs for health care providers and educators. Yet, when ignored, they can have consequences impacting the relational dimension of care, prevention of relapses, disease complications, health education and behaviour change.

Methods:

Based on a critique of the psychosocial conceptual models used in prevention, this study combines a qualitative approach aimed at identifying and describing mothers' perceptions about paediatric cancer and diabetes, transforming them into educational content that can be reused for the training of health care providers and educators; and a quantitative component, obtaining their impact on the therapeutic relationship and therapeutic compliance.

Results:

The results show that caregivers (healers, physicians), children, mothers and their close family are involved in the relational component of care; the Cameroonian mother expects that the therapist consulted should be a psycho-oncologist or a psycho-diabetologist, who can (power) and knows (knowdlege). Maternal perceptions determine the techno-therapeutic dimension, and may, if ignored, threaten therapeutic adherence, leading to abandonment.

Conclusions:

This study suggests integrating maternal perceptions of cancer and diabetes with the messages used to elaborate languages for health education and caregiver training, to associate the healers to the early screening of cancer and diabetes, and to their educational, preventive and therapeutic care. Also suggested by this research is consideration of the relational dimension as a care service, and maternal perceptions as an illness that will need to be treated like cancer and diabetes.

Key messages:

- Associate the healers to the early screening of cancer and diabetes, and to their educational, preventive and therapeutic care.
- Considering relational dimension as a care service, and maternal perceptions as an illness that will need to be treated like cancer and diabetes.

From the experience of planning a life with diabetes to the mechanisms of the management of illness

Matchika Megaptché Mathilde

MM Mathilde[1], WA André[2], KNP Paul[3]

[1]Sociology, University of Yaounde I, Yaounde, Cameroon
[2]Sciences of Education, University of Yaounde I, Yaounde, Cameroon
[3]Paediatrics, University of Yaounde I, Yaounde, Cameroon
Contact: mmatchika@gmail.com

Background:

In the context of chronic diseases, it is now recognized that experiences of planning a new life with diabetes are very informative, and are a source of knowledge that can be used to improve patient care and quality of life. However, the professionals in health and the patients' therapeutic education are still struggling to translate this knowledge into their practices or to make use of it, as long as its forms remain largely unknown and it is not known how to identify these. Objective: The study aims to identify these knowledges and to report on how it is produced, based on an analysis of the experiences of diabetic patients in Yaoundé, Cameroon.

Methods:

The study combines a phenomenographic approach aiming at ethnographing the form and contents of lessons learned from life experiences with diabetes; and an operation of reflexive ethnography centered on the patient, apprehending the process of elaboration or production of these teachings. It includes six diabetics selected from the typical sampling method. The data collected were analysed using paradoxical analysis and interpreted in a pragmatic perspective.

Results:

The results reveal various mechanisms of self-management of the disease and stigma, developed by patients, such as: identity recomposition; valorization of treatment by promoting its benefits to others; control of information about one's illness oscillating between concealment and disclosure; therapeutic adjustments according to the life situations or interactions; rearrangement of individual and family habits; listening and decoding of the language of illness, body and the effects of food on the body; learning of conceptualized knowledge about diabetes and nutrition through various sources of information.

Conclusions:

the study suggests that these mechanisms should be considered as relevant forms of knowledge; and the should be used to improve both preventive, therapeutic and educational practices and the quality of life of the diabetics.

Key messages:

- The mechanisms of self-management of diabetes and stigma develop by diabetics trough their experience of planning a new life with diabetes should be considered as relevant forms of knowledge.
- These mechanisms should be used by health professionnals and patients' education professionals to improve their practices and the quality of life of diabetics.

Preventive actions for the gradual reduction of excessive salt intake and its monitoring in Italy

Chiara Donfrancesco

C Donfrancesco[1], P Bellisario[2], D Galeone[2], C Lo Noce[1], O Russo[3], L Palmieri[1], S Giampaoli[1], P Strazzullo[3]
[1]Cardiovascular, Endocrine-metabolic Diseases and Aging, Istituto Superiore di Sanità, Rome, Italy
[2]Italian Ministry of Health, Rome, Italy
[3]ESH Excellence Centre of Hypertension, Federico II University of Naples Medical School, Rome, Italy
Contact: chiara.donfrancesco@iss.it

Issue:

The WHO Global Action Plan for the Prevention of NCDs recommends a 30% relative reduction in mean population intake of salt/sodium. To this end, the Italian Ministry of Health (MoH) has strengthened prevention and health promotion through the ''Gaining health: making healthy choices easy'' Programme and the National Preventive Plan (NPP) 2014-2019, with the collaboration of the Interdisciplinary Working group for Salt Reduction in Italy (GIRCSI).

Description of the problem:

According to the ''Gaining Health'' Programme, agreements between the MoH and the associations of artisan bakers and food industry companies were signed since 2009 to reduce the salt content in bread and in other food products. The reduction of excessive salt intake is one of the main objective of the NPP 2014-2019 pursued by the Regions through initiatives as local inter-sectors agreements and information activities for the population and training for food sector operators. The Italian Institute of Health conducts national surveys to estimate habitual salt intake in the general adult population by collecting 24h urine. Baseline assessment was in 2008-2012 from random samples of persons aged 35-79 years, resident in all 20 Regions. A new survey is ongoing (2018-2019) involving persons aged 35-74 years, resident in 10 Regions. Surveys are funded by the MoH-CCM; urinary sodium excretion is effected by a central lab at Federico II University of Naples, subjected to strict quality controls.

Results:

The baseline survey showed a mean sodium excretion of 10.6 g/24h (95% confidence interval 10.5-10.8) in 1963 men and 8.2g/24h (8.1-8.4) in 1894 women. Results of the ongoing survey are expected in the coming months.

Lessons:

In Italy preventive actions of salt reduction supported by the MoH have been implemented. Estimation of salt intake in diet by 24h/urine is included. Results of baseline and on-going surveys will allow to estimate the possibility of meeting the WHO salt reduction target by 2025.

Key messages:

- In Italy inter-sectors preventive actions of salt reduction are implemented.
- Results of the baseline and on-going surveys will allow to estimate in Italy the possibility of meeting the WHO salt reduction target by 2025.

Predicting musculoskeletal disorders risk using tree-based ensemble methods

Pierre Michel

A Paraponaris[1,2], A Ba[3], E Gallic[1], Q Liance[3], P Michel[1]
[1]Aix-Marseille School of Economics, Aix-Marseille University, Marseille, France
[2]ORS PACA, Southeastern Health Observatory, Marseille, France
[3]Novacare, PROGEXIA, Marseille, France
Contact: pierre.michel@univ-amu.fr

Background:

Musculoskeletal disorders (MSD) can cause short-term disorders and permanent disabilities which may all result in serious limitations in activities of daily living. According to the WHO, MSD are the second largest cause of disability worldwide. In France, preventing MSD became a challenge for both the sickness fund and the complementary health insurers as the MSD prevalence increased by more than 50% since 2003, the MSD representing more than 80% of the occupational diseases leading to sick-leaves or financial compensations in 2015.

Methods:

Data from the IRDES 2012 health and social welfare survey (ESPS, enquête santé et protection sociale) was matched with individual care consumptions from the French health insurance. The ESPS survey is a national representative survey including 23,047 CATI/CAPI interviewed individuals (participation rate: 66%). Respondents self-assessed their health status, including MSD among other health troubles. Prediction of MSD risk was designed as a supervised binary classification problem, with the help of Random Forest (RF) and Gradient Boosting Machine (GBM) methods.

Results:

Variable importance scores based on the squared error criterion over all trees were computed for the continuous and categorical variables supposed to be associated with MSD: the consumption of medicines, physiotherapists' and GPs' services, medical imaging, biomedical analyses, dental care, and sociodemographic features (occupation, age and income). Slightly better results were obtained with GBM compared to RF (overall test accuracy rate: 70% for both methods).

Conclusions:

Machine learning methods with merged survey and registry data may help health insurers to better identify the individual MSD risk and prevent the occurrence and the disabling consequences of MSD with the help of individualized prevention strategies.

This research is financially supported by Malakoff Mederic Humanis, life & health French insurance for employees and individuals.

Key messages:

- The use of machine learning methods may be of interest to improve the ability to predict the MSD risk and help to identify insured people whom individualized prevention strategies can be offered to.
- Matching survey and health insurance liquidation data improves the ability to identify people at improved risk of MSD and gives the opportunity to provide them resources to prevent and to cope with.

Mortality inequalities from major causes of death in Lithuania by education during 2001-2014

O Meščeriakova-Veliulienė

O Meščeriakova-Veliulienė[1], R Kalėdienė[1], S Sauliūnė[1], S Kaselienė[1]
[1]Lithuanian University of Health Sciences, Kaunas, Lithuania
Contact: mes.olga@gmail.com

Background:

The aim of the study was to evaluate mortality inequalities from major causes of death by education in Lithuania during 2001-2014.

Methods:

Information on deaths (aged 30+) from cardiovascular diseases (ICD-10 codes I00-I99), cancer (ICD-10 codes C00-C97), external causes (ICD-10 codes V01-Y98), and digestive system diseases (ICD-10 codes K00-K93) was obtained from Statistics Lithuania. Mortality rates from these causes were calculated by the level of education (high (post-secondary non-tertiary, tertiary) and low (unknown, preprimary or no education, primary, lower secondary, upper secondary)) per 100,000 person-years. For the assessment of mortality trends during 2001-2014, the Joinpoint regression analysis was applied.

Results:

During the analyzed period, mortality from all major causes was higher in the lower educational group ($p < 0.05$). The most prominent differences in mortality rates between educational groups were found from external causes and cardiovascular diseases. Mortality from cardiovascular diseases (by 2.22% per year), cancer (by 1.87% per year) and particularly from external causes (by 5.2% per year) declined in higher educational group ($p < 0.05$). In the lower educational groups mortality declined only from cardiovascular diseases (by 0.73% per year), however mortality increased from cancer (by 0.64% per year) and digestion system diseases (by 5.20% per year) ($p < 0.05$).

Conclusions:

Mortality from major causes of death in both educational groups changed unevenly during 2001-2014. In higher educational group mortality declined from cardiovascular diseases, cancer, and especially from external causes, while in lower educational group - just from cardiovascular diseases.

Key messages:

- In Lithuania, there are still significant inequalities in mortality from the major causes of death by education.
- Therefore, more attention should be paid for the improvement of the health of the population with lower education.

Prevalence of multiple sclerosis in the South of Italy based on healthcare administrative data

Raffaele Palladino

R Palladino[1,2], V Brescia Morra[3], R Lanzillo[3], R Giordana[5], MG Fumo[6], P Montuori[1], MP Sormani[7], M Triassi[1], M Moccia[3,4]
[1]Department of Public Health, University, Naples, Italy
[2]Department of Primary Care and Public Health, Imperial College, London, UK
[3]Multiple Sclerosis Clinical Care and Research Centre, University, Naples, Italy
[4]Queen Square MS Centre, University College London, London, UK
[5]Campania Region Healthcare System Commissioner Office, Regional Office, Naples, Italy
[6]Regional Healthcare Society, Regional Office, Naples, Italy
[7]Biostatistic Unit, University of Genoa, Genoa, Italy
Contact: palladino.raffaele@gmail.com

Background:

Multiple sclerosis (MS) is an heterogenous disease whose prevalence varies in Europe. Hereby, we aimed to estimate prevalence of MS in the Campania Region of Italy.

Methods:

To identify individuals with MS living in the Campania Region of Italy, we extracted data from the following healthcare administrative databases: hospital discharge records, regional drug registry, and specialist outpatient visits from Jan-2015 to 3Dec-2017. Individuals alive on the 1-Jan-2018 were included to capture prevalence on this date. Age-sex standardised prevalence rates were calculated using the direct standardisation method; the European population in 2018 was considered as reference population. To assess differences in the prevalence ratios across the five provinces of the region, standardised morbility ratios (SMR) were calculated. To calculate 95% confidence intervals (95%CI) for the standardised rates, the Byar's approximation method based on the Poisson distribution was used.

Results:

We identified 5,361 individuals with MS (females 64.5%, age 45.6±12.7 years). Standardised prevalence rate per 100,000 people was 90.0 cases (95%CI = 87.60, 92.40) (112.07 for females [95%CI = 108.36, 115.88] and 66.20 for males [95%CI = 63.26, 69.25]). The SMR in the province of Naples, the most densely populated, was 0.90 (95%CI = 0.86, 0.96), whereas the highest SMR was found in the province of Salerno (SMR = 1.30; 95%CI = 1.23, 1.38), and the lowest in the province of Caserta (SMR = 0.89; 95%CI = 0.82-0.96).

Conclusions:

Prevalence of MS in the Campania Region is lower than previous estimates from smaller areas in the North of Italy, suggesting a longitudinal gradient. Differences within the Region could be explained by genetic/environmental background and healthcare organization (e.g., missing diagnoses). In the future, healthcare administrative databases could be used to monitor MS prevalence/incidence and to plan healthcare resource utilization.

Key messages:

- Prevalence of MS in the Campania Region is 90 cases per 100,000 people. It is lower than previous estimates from smaller areas in the North of Italy, suggesting a longitudinal gradient.
- Differences within the Region could be explained by genetic/environmental background and healthcare organization (e.g., missing diagnoses).

Improving participation of detained men in organised screening of colorectal cancer in Toulon

Mélanie Porte

M Porte[1], MD Harmel[2], L Pernice[3], M Misserey[3], C Adam[3], J Sondey[1], L Pallier[1]
[1]Comité Départemental d'éducation pour la Santé du Var, La Garde, France
[2]Centre de Coordination du Dépistage des Cancers SUD PACA antenne du Var (ex-ISIS 83), La Garde, France
[3]Unité Sanitaire en Milieu Pénitentiaire (USMP) du Centre Hospitalier de Toulon, La Seyne-sur-Mer, Toulon, France
Contact: m.porte@codes83.org

In France, organised screening for colorectal cancer was set up in 2008. Participation rate was assessed in March 2014 at the prison of Toulon / La Farlède. On the 100 detained men aged 50-74 years old concerned by screening, only 3.9 % were screened. A project aiming at improving participation in screening while addressing specific difficulties related to prison settings (lack of privacy in cells, low socioeconomic and education status of the population, stronger exposition to risk factors for colorectal cancer) was launched in 2015 and has been yearly conducted since then.

How to improve colorectal cancer screening in a prison setting? How to organise a sustainable screening program? What proximity guidance should be provided to foster participation?

The program that was developed mainly consisted in awareness sessions and proximity guidance to testing. Among the 330 detained men targeted between 2015 and 2018, 165 men performed an immunologic test (57.9%) and 45 were excluded for medical reasons. Colonoscopy was performed for 10 of the 13 men with a positive result and lesions were detected for 9 men. Among them, one cancer, 6 high-risk polyps and 2 low-risk polyps were found. Those findings exceeded expected numbers.

Despite a small population sample, data revealed the benefit of the project in comparison with other participation rates: only 33.5% in France and 29.3% in the Var department (estimates for 2016-17 by Santé Publique France). Furthermore, we achieved a participation rate compliant with European recommendations establishing 45% as a minimum target.

The success of our program relied on the synergy between health prevention professionals screening organisers and prison medical staff. Strong involvement of each team constituted a real leverage for project to ensure effective proximity guidance for detained persons leading them to get screened.

Key messages:

- Awareness program adapted to prison improved participation in colorectal cancer organised screening.
- Proximity guidance helped to detect cancer and to improve medical care of detained persons.

Elevated fatty liver index as a risk factor for all-cause mortality in HIV-HCV co-infected patients

[13]IPLESP UMRS 1136, INSERM/University Sorbonne/University Paris 6, Paris, France
Contact: tanguibarre@hotmail.fr

Background:

Thanks to innovation in treatment, people living with HIV and/or HCV now live longer but are growingly facing non-communicable disease burden. HIV-HCV co-infected patients are at high risk of metabolic complications and liver-related events, which are both associated with hepatic steatosis and its progressive form, non-alcoholic steatohepatitis (NASH), a known risk factor for mortality. The fatty liver index (FLI), a non-invasive steatosis biomarker, has recently drawn attention for its clinical prognostic value, but has never been applied to HIV-HCV co-infected patients. We aimed at testing whether elevated FLI (≥60) was associated with all-cause mortality in co-infected patients.

Methods:

Our study is based on data from ANRS CO13 HEPAVIH, a French national prospective cohort of HIV-HCV co-infected patients. Socio-behavioral and clinical data from patients clinically followed-up were used in the analysis. Using a Cox proportional hazards model for mortality from all causes (983 patients; 4,432 visits), we computed hazard ratios associated with risk factors and confounders.

Results:

After multiple adjustment, individuals with FLI≥60 had almost double the risk of all-cause mortality (adjusted hazard ratio [95% confidence interval]: 1.91 [1.17-3.12], p = 0.009), independently of HCV cure (0.21 [0.07-0.61], p = 0.004), advanced fibrosis (1.77 [1.00-3.14], p = 0.05), history of hepatocellular carcinoma and/or liver transplantation (7.74 [3.82-15.69], p < 10-3), history of indirect clinical signs of cirrhosis (2.80 [1.22-6.41], p = 0.015), and HIV CDC clinical stage C (2.88 [1.74-4.79], p < 10-3).

Conclusions:

An elevated fatty liver index is a risk factor for all-cause mortality in HIV-HCV co-infected patients independently of liver fibrosis and HCV cure. In the present era of nearly 100% HCV cure rates, these findings encourage the more systematic use of non-invasive steatosis biomarkers to help identify co-infected patients with higher mortality risk.

Key messages:

- A FLI≥60 is strongly associated with mortality in HIV-HCV co-infected patients.
- FLI could be calculated routinely to identify most at-risk patients.

Ketoacidosis admission rate in type 2 diabetes mellitus patients from 2006 to 2015 in Abruzzo, Italy

Francesca Meo

F Meo[1], P Di Giovanni[2], F Cedrone[1], G Di Martino[1], P Scampoli[1], T Staniscia[3]
[1]School of Hygiene and Preventive Medicine, ''G. d'Annunzio'' University of Chieti-Pescara, Chieti, Italy
[2]Department of Pharmacy, ''G. d'Annunzio'' University of Chieti-Pescara, Chieti, Italy
[3]Department of Medicine and Ageing Sciences, ''G. d'Annunzio'' University of Chieti-Pescara, Chieti, Italy
Contact: francesca.meo10@gmail.com

Background:

Diabetic ketoacidosis (DKA) is a potentially life-threatening but largely preventable complication of diabetes and is associated with significant health care utilization and expenditure. Whereas DKA is mostly related to type 1 diabetes, over recent years an increasing number of hospital admissions for DKA have been reported in adult subjects with type 2 diabetes. The aim of this study was to assess the trend of hospitalizations for DKA in adult patients with type 2 diabetes and its associated factors.

Methods:

A retrospective cross-sectional study was performed from 2006 to 2015 in Abruzzo region. Data were collected from hospital discharge records (HDRs) of type 2 diabetes adult patients with either primary or secondary diagnosis for DKA. Age-adjusted hospitalization rates were computed by gender and standardized on the regional population in 2006. A logistic regression model was implemented using the presence of DKA as dependent variable.

Results:

We identified 160,366 HDRs with type 2 diabetes. Out of them, 1611 (1.00%) were due to DKA. The hospitalization rates for DKA increased both for male +115.9 and female +142.8%, from 2006 to 2015. Associated factors of DKA were age ranging from 18 to 44 (adjOR = 4.17; 95%CI:3.27-4.31), uncontrolled diabetes (adjOR = 1.79; 95%CI:1.60-2.01), trauma (adjOR = 1.38; 95%CI:1.13-1.68), any infection (adjOR = 1.68; 95%CI:1.22-.2.33), liver disease (adjOR = 1.29; 95%CI:1.09-1.53), fluid and electrolyte disorders (adjOR = 2.09; 95%CI:1.09-1.53), psychosis (adjOR = 1.69; 95%CI:1.25-2.30).

Conclusions:

Hospitalization trends for DKA in adult patients with type 2 diabetes have been increasing and are associated with some comorbidities. Early screening, appropriate patients, families and communities education remain an important aspect of preventing an acute diabetic complication such as DKA.

Moreover, multimorbidity complicates the disease management and remains an open challenge for public health.

Key messages:

- This study addresses hospitalizations for DKA in adult patients with type 2 diabetes, an occurrence increasing worldwide for unclear reasons.
- For preventing DKA in type 2 diabetes patients, it is useful taking into consideration the known trigger factors, but it is also worthwhile improving the management of comorbidities in outpatients.

Management of COPD in Anhui Province: compliance with GOLD guidelines

Shizhen He

S He[1,2], L Zha[2,3,5], Y Li[4], G Yang[4], Y Zhou[4], EV Villanueva[2]
[1]Department of Public Health Science, Karolinska Institutet, Solna, Stockholm, Sweden
[2]Department of Public Health, Xi'an Jiaotong-Liverpool University, Suzhou, China
[3]Intensive Care Unit, Conch Hospital, Wuhu, China
[4]Department of Respiratory & Critical Care Medicine, The Second People's Hospital of Wuhu, Wuhu, China
[5]Institute of Infection and Global Health, University of Liverpool, Liverpool, UK
Contact: shizhen.he@stud.ki.se

Background:

COPD is a major public health concern of global scope, especially in China. The Global Initiative for Chronic Obstructive Lung Disease (GOLD) guidelines are international and national recommendations to manage COPD. Little is known about level of adherence of COPD management among exacerbated COPD inpatients to GOLD guidelines in China. The current study aimed to compare COPD management (vaccination and treatment of COPD exacerbation) among hospitalized patients in Anhui Province with GOLD guidelines and identify risk factors influencing vaccination coverage and guideline-compliant care.

Methods:

A retrospective clinical audit of medical records was conducted in a hospital in Anhui Province in China, involving 1132 patients hospitalized with exacerbated COPD within 2016-2017. Descriptive analysis was conducted to evaluate compliance to GOLD recommendations (version 2017). Logistic regression was conducted to detect the association between guideline-consistent care and variables.

Results:

Extreme deficiency in the vaccination coverage (0%) was found. Regarding pharmacological management, some adherence to prescribing short-acting bronchodilators timely (43.5%) and prescribing long-acting bronchodilators (55.0%) was observed; nonetheless, only 26.1% of patients received systemic corticosteroids or antibiotics for the recommended duration (<7 days) and only 17.0% did not receive methylxanthines. Age, education level, occupational status and disease severity were independently associated with guideline-consistent treatment.

Conclusions:

The implementation of GOLD recommendations in Anhui Province was unsatisfactory. Interventions to increase the vaccination coverage among COPD patients and to optimize the treatment of COPD exacerbation are imperative, requiring efforts at the hospital and policy levels.

Key messages:

- This is the first clinical audit study investigating the COPD management among hospitalized COPD patients in China.
- The implementation of GOLD recommendations in Anhui Province was unsatisfactory.

Geographic disparities in bladder cancer incidence among men in the department of Bouches-du-Rhône

Laurence Pascal

K Mantey[1], S Cortaredona[2], V Grisoni[3], M De Fromont[4], P Albert[5], G Karsenty[6], L Pascal[7]

Bladder cancer incidence is investigated in the department of Bouches-du-Rhône to provide answers to the population reporting an excess of cancer cases in industrial areas. The study aimed to describe the geographical variations of bladder cancer incidence among men and detect potential spatial clusters without point source specification.

Incident cases diagnosed between 2013 and 2016 were extracted from the departmental observatory of cancers REVELA13. Age-standardized incidence ratios (SIRs) were calculated for each commune and bayesian smoothed risk estimate based on the Besag, York and Mollie model were computed for incidence mapping. Morans'I, Potthoff-Whittinghill and Tango statistic tests were used to investigate global clustering and the spatial scan statistic of Kulldorf (SaTScan) was used to investigate local clustering. Analyses were adjusted on a French deprivation index, access to health-care services and population density.

During the study period, 1 735 cases of bladder cancers were diagnosed among men. The study found a spatial heterogeneity ($p < 0.01$) and aggregation ($p < 0.01$) but no spatial autocorrelation ($p = 0.09$). Bayesian smoothed SIRs were not related to the confounding factors studied. An over-incidence was observed in the communes located in the South East of the department including Marseille, the biggest city of the study area. SaTScan algorithms detected two significant high-risk clusters in the same area (RR = 1.50 and 1.38). Introduction of each confounding factors in spatial scan detection, changed slightly the shape of clusters and/or the value of the relative risk but not the location. None high-risk cluster was detected in the communes of the industrial area.

Spatial analysis provides a first answer to the population concerning an excess of risk of bladder cancer at commune level. However, more analysis should be led to identify etiological factors or common environmental exposure.

Key messages:

- Geographic disparities exist in bladder cancer incidence among men at a commune level in the department of Bouches-du-Rhône.
- Spatial analysis show excess of risk of bladder cancer in the south-east of the department including the urban area of Marseille.

The analytic hierarchy process as a holistic model for the assessment of dialysis centres

Magdalena Barbara Kaziuk

MB Kaziuk[1], W Kosiba[2]
[1]Jagiellonian University Medical College, Krakow, Poland
[2]2nd Internal Branch with Intensive Cardiology Care of the Zeromski Hospital, Krakow, Poland
Contact: magdalenak286@poczta.fm

Introduction:

Haemodialysis is one of the methods of renal replacement therapy which is most frequently used in Poland and in the world in patients with chronic and acute renal failure. Purpose: An attempt was made to have patients undergoing regular haemodialysis assess the results of activity of dialysis centres.

Methods:

64 patients (30 women, 34 men, age: 50.2 +/- 11.9 years) undergoing dialysis therapy in three selected dialysis centres in Poland were included in the study. A questionnaire correlated with the analytic hierarchy process (AHP) was employed for the assessment. The dialysis centres were assessed by the patients in the context of availability of services, communication between the medical staff and the patient and the

treatment used. Two sub-criteria were connected with each criterion, for which significance (priorities) indicating a dependent impact on the assessment of the quality of dialysis centres was calculated.

Results:

From amongst four domains of the assessment of dialysis centres, the patients rated medical care and nursing care the highest (w = 0.386), where medical care had significance equal to 0.455, and nursing care had significance equal to = 0.545. The next important part of the assessment of dialysis centres was communication between the medical staff and the patient (w = 0.321) and the treatment used (haemodialysis) (w = 0.155). Availability of services had the lowest significance (w = 0.138), including performance of examinations for kidney transplant and medical transport for haemodialysis.

Conclusions:

The assessment of dialysis centres using the AHP method should be part of the therapeutic process where one needs to emphasise the role of the patient in chronic nephrological care which translates into the quality of services provided by dialysis centres.

Key messages:

- The assessment of dialysis centres using the AHP method should be part of the therapeutic process.
- The patient's role and its good assessment in the treatment process is very important.

Nutritional and Rehabilitation goals in Acquired Brain Injury patients: a new decannulation protocol

Matteo d'Angelo

M d'Angelo[1], A Michelutti[2], E Biasutti[2], R Quattrin[3], S Brusaferro[4]
[1]Department of Medicine, University of Udine, Udine, Italy
[2]Institute of Physical and Rehabilitation Medicine, Udine Healthcare and University Integrated Trust, Udine, Italy
[3]Accreditation, Clinical Risk Management and Performance Assessment, Udine Healthcare and University Integrated Trust, Udine, Italy
[4]Department of Medicine, Udine Healthcare and University Integrated Trust, Udine, Italy
Contact: matteo.dangelo@uniud.it

Background:

One of the first goals for the rehabilitation of patients with Acquired Brain Injury (ABI) is the removal of the tracheocannula: the aim is not only to allow respiration by airways and reduce respiratory complications but also to obtain rehabilitation of dysphagia and verbal communication: for this purpose from July 2017 the ABI unit of the Institute of Physical and Rehabilitation Medicine 'Gervasutta'' adopted a new decannulation protocol, recommended by the Italian Society of Physical Medicine and Rehabilitation (SIMFER).

Methods:

Clinical data of ABI patients with tracheal cannula from May 2014 were collected as both process and outcome indicators associated with the adoption of the new protocol were defined. ABI patients were therefore divided into two groups depending on whether they were treated with or without the new procedure. Data have been processed with ''Simple Interactive Statistical Analysis'' (SISA) software.

Results:

A sample of 141 patients with tracheocannula was analyzed; among these 57 (40.4%) were treated with the new decannulation protocol. No statistical significant differences were found between the two groups in terms of systemic or respiratory complications, Functional Independence Measure (FIM) or Level of Cognitive Functioning (LCF) at the entrance as well as for both the time (days) between entry or tracheotomy and decannulation. However decannulation rate is significantly higher when the new protocol is applied (OR = 1.8; 95% CI = 1.2- 9.8; p = 0.01) as the time (days) between entry and oral feeding resumption ($p < 0.001$; 95% CI = -10 - -34 days).

Conclusions:

The introduction of the new protocol has allowed the achievement of both nutritional and rehabilitation goals with a significantly faster oral feeding resumption and an increase of decannulation rate and. Further efforts are needed to support its use in the future, with the aim of further improving of either process or outcome performances.

Key messages:

- Promising prospects for the decannulation of patients with acquired brain injury.
- Achievement of nutritional and rehabilitation goals.

Health Literacy Profile and educational intervention as a prevention action for Type2 Diabetes

B Sabeena Dowlut

SD Dowlut[1], MBD Balcou Debussche[2], XD Debussche[3]
[1]Applied Informatics, Université Des Mascareignes, Rose Hill, Mauritius
[2]ICARE, Reunion University, St Denis, La Réunion
[3]CHU, Reunion, St Denis, La Réunion
Contact: sdowlut@udm.ac.mu

Diabetes Type 2 is being categorized as a health crisis in Mauritius where 22.8% of the population suffers from it coupled with a 19.5% who are pre-diabetic. Government is already spending a huge proportion of the national budget in care of diabetic patients. Since one of the known means to better control diabetes is structured diabetes education, we tested the ''learning nests'' as a prevention measure for Type2 Diabetes. The ''learning nests'' is a structured health education programme which takes into account both biomedical and psychosocial dimensions which has already proved its effectiveness in other countries and it is theoretically based on socio-constructivism, social contextualization, empowerment and action planning.

Health literacy refers to the capacity to access, understand and use health related information to make appropriate health decisions. A concept which is highly correlated to the health outcomes of a population since it addresses necessary competencies to maintain oneself in good health.

The objectives of the educational sessions were to educate people on the risk factors of diabetes and at the same time these people can disseminate the knowledge acquired in their social environment. Six educational sessions were organized for 30 participants whereby the main eligibility criteria was age > = 18 years. A qualitative study was conducted with the participants to analyse the learning process as well as their health literacy competencies in terms of access, comprehension and evaluation of health information. The study was conducted before and after three structured educational sessions based on cardiovascular risks, Physical Activities and managing fat intake.

The findings show that these learning situations when contextualized can prove to be promising, in terms of health actions being undertaken by participants and improvement in health literacy competences in a middle-income country like Mauritius.

Key messages:

- Improvement of Health Literacy level can decrease the prevalence of Diabetes.
- Structured Health Education can help in improving health literacy.

Network of Vascular Centers in the Russian as a way to reducing mortality in the working population

Aleksandr Zubko

A Zubko[1,2], T Sabgayda[1,3], P Shelekhov[1], V Zaporozhchenk[1], E Zemlyanova[1]
[1]Statistia, Federal Research Institute for Health Organization and Informatics of Ministry of Health of Russian, Moscow, Russia
[2]A.N. Bakulev National Medical Research Center of Cardiovascular Surgery, Moscow, Russia
[3]Health and Self-conservation Behavior, The Institute of Russian Academy of Sciences the Institute of Socio-Political Research, Moscow, Russia
Contact: zalexandrae@gmail.com

Over the entire period of the state program aimed at reducing mortality from circulatory system diseases initiated in 2008 the number of Vascular Centers has increased from 85 to 140.

According to the federal statistical observation form, the rate of Vascular Centers per 100 000 population increased 1.5 times from 0.066 to 0.095 in 2008 and 2017 respectively. As a result, the number of treated patients increased 6.3 times - from 53.1 to 327.3 per 100 000 population. During the analyzed period, the mortality rate of patients of Vascular Centers decreased from the average of 9.3% for all Vascular Centers in 2009 to 7.6% in 2017 ($\chi 2 = 248.6$, $p < 0.0001$) reflecting accumulation of experience of care delivery within the framework of the state program.

The majority of patients with myocardial infarction and cerebrovascular diseases received treatment in the Vascular Centers. In 2017, 76.6% of all patients were admitted to Vascular Centers. From 2008 to 2017, the mortality from circulatory diseases in urban males of working age decreased by 36.1% (from 354.6 to 226.6 per 100 000 population), while cardiovascular mortality in rural males decreased to a greater extent - by 41.0% (from 394.2 to 232.0). Female mortality from circulatory system diseases (the level of which was initially five times lower) decreased to a lesser extent: from 67.0 to 44.5 per 100 000 urban females of working age (1.5 times - by 33.6%), and was even more pronounced in rural females - from 90.8 to 55.4 (by 39.0%).

Therefore, along with the increase in the number of Vascular Centers the volume of specialized care including high-tech, increases while mortality decreases, reflected by the decreased mortality from myocardial infarction and other forms of acute ischemic heart disease. However, the activity of Vascular Centers did not affect the rate of mortality from cerebrovascular diseases in the Russian population.

Key messages:

- Through the activity of regional vascular centers since 2008 substantial reducing of patients' mortality was registered from myocardial infarctions and other acute forms of ischaemic heart disease.
- Mortality from myocardial infarction has decreased in the last decade faster than in the period up to 2009.

Prognostic value of the Diverticular Inflammation and Complication Assessment (DICA) classification

Gabriella Nasi

G Nasi[1]*, AM Mastromatteo*[1]*, G Cambiè*[2]*, F Di Mario*[2]*, W Elisei*[3]*, M Franceschi*[4]*, A Nouvenne*[2]*, A Tursi*[5]*, A Violi*[2]*, G Brandimarte*[6]

[6]Division of Internal Medicine and Gastroenterology, Cristo Re Hospital - GIOMI, Rome, Italy
Contact: gabrynasi@gmail.com

Colonic Diverticulosis is one of the most common anatomic alterations found in the clinical practice. This condition has 60% incidence in the population over 60 years old. About 20% of patients with this condition will develop Diverticular Disease, and 5% of them will evolve into Diverticulitis. The aim of the study is to analyse the validation of the classification considering the distribution of the severity DICA score between the patients with diagnosis of colonic Diverticulosis.

We analysed and classified with DICA 5635 colonoscopies in the period between January 2012 and April 2018 and we obtained the Hospital Discharge Form from all the patients that had been admitted to the hospital in the same time period. The results showed that 69.9% of the patients were assigned to the score DICA1, 21% to DICA2 and 9.1% to DICA3. Ageing increased both the diagnosis of Diverticular Disease and the severity score. The severity was higher in female patients (DICA1 = 44.6%,DICA2 = 50.8%,DICA3 = 57.8%). The occurrence of complications overall was 5.4% and specifically: not complicated Diverticular Disease (DICA1 = 1%, DICA2 = 1.8%, DICA3 = 3.5%); not complicated Diverticulitis (DICA1 = 2.1%, DICA2 = 4.7%, DICA3 = 6.4%); Bleeding in Diverticulitis (DICA1 = 0.4%, DICA2 = 1.2%, DICA3 = 4.5%); Diverticular Perforation (DICA1 = 0.0%, DICA2 = 0.1%, DICA3 = 0.4%). The complications that needed a surgical procedure were for DICA1 about 0.2%, for DICA2 0.8% and for DICA3 2.5%. As well the average of the occupant days in the hospital and the cost, respectively, was for DICA1:8.5 days and 2300 €; for DICA2:9.5 days and 3080 €; for DICA 3:13 days and 4090 €.

The majority of the patients with Diverticular Disease belonged to the severity score DICA1 and the patients classified with DICA3 were mainly female and older than 69 years old. The study confirmed the prognostic value of the endoscopic classification DICA since the occurrence of complication resulted in a statistically significant relation with the score DICA3.

Key messages:

- DICA classification was able to discriminate, based on endoscopic records, the patients that could develop complications for Diverticular Disease.
- DICA classification is a valid parameter to predict the outcome of the disease, with great impact on public health improving the effectiveness of treatment.

Improving chronic diseases management using Learning from Excellence (LfE) model

Alice Borghini

A Borghini[1]*, F Vola*[1]*, F Pennucci*[1]*, C Seghieri*[1]*, S Nuti*[1]
[1]Institute of Management - MeS Lab, Scuola Superiore Sant'Anna, Pisa, Italy
Contact: alice_borghini@santannapisa.it

Background:

Learning from excellence (LfE) model demonstrated to be an effective method in the promotion of quality improvement in healthcare and in the reduction of patient's harm. We applied LfE to identify the best models that could represent the excellence in the management of chronic heart failure (CHF) patients among the models adopted among 98 healthcare providers across 10 Italian Regions.

Methods:

The research consisted of 2 phases: 1) the creation of a 9 indicators set to map CHF pathways and the analysis of these indicators through a quantitative approach using a modified positive deviance model which identified the best performers among our sample of hospitals and local health authorities (H/LHA) grouped in geographical Areas. We transformed 3 indicators (''tracking'' indicators) into a 0-5 scale to assure direct comparison. 2) The H/LHA best performers were asked to share their organizational and clinical model during a workshop where every stakeholder involved could take part.

Results:

Among the 10 investigated Italian Regions, 42 Areas were ranked and ranged 1,83-3,91. The three best performing areas that ranked above the 3rd quartile and were interested in taking part in this new approach were selected. The results arising from the qualitative analysis of these areas showed that communication, trust and shared goals among healthcare professionals resulted to play a key role among the best performing H/LHA. Indeed, the same role is played by all the policies and practices that enabled Interactions among healthcare workforce and patients, thus representing the 'integration of care'.

Conclusions:

The identification-celebration of best performers LfE implementation model holds the potential to promote quality improvement of processes among healthcare providers. This potential also unlocks in the chronic disease management field, making the sharing of best performers' experience possible at a Regional and National level.

Key messages:

- Learning from excellence model demonstrated to be an effective method in the promotion of best models in the management of chronic diseases.
- Communication, trust and shared goals among healthcare professionals resulted to play a key role among the best performing hospital and local health authority.

Diabetes in Israel- do all patients receive equal care?

Ronit Calderon-Margalit

Y Wolff Sagy[1,2], *M Krieger*[1,2], *E Horwitz*[2,3], *A Ben-Yehuda*[2,4], *O Paltiel*[2,5], *S Ravel-Vilk*[2,6], *O Manor*[1,2], *R Calderon-Margalit*[1,2]
[1]Braun School of Public Health & Community Medicine, Hebrew University, Jerusalem, Israel
[2]National Program for Quality Indicators in Community Healthc, Israel National Institute for Health Policy Research, Tel Hashomer, Israel

[4]Internal Medicine, Hadassah Medical Center, Jerusalem, Israel
[5]Hematology, Hadassah Medical Center, Jerusalem, Israel
[6]Pediatric Hemato-Oncology, Shaare Zedek Medical Center, Jerusalem, Israel
Contact: ronitcm@gmail.com

Background:

Diabetes Mellitus (DM) is associated with micro- and macrovascular complications, leading to high burden of morbidity and mortality. Populations of low socioeconomic position (SEP) in various countries were found to have increased prevalence of the disease, worse glycemic control, and increased complications. We aimed to examine whether there are social disparities in diabetes care in Israel, as reflected in a national program for quality indicators.

Methods:

The Israel National Program for Quality Indicators in Community Healthcare obtains data from electronic medical records from all health plans, covering the entire Israeli population. In 2017, 497,397 individuals aged >18 years were identified with DM. DM prevalence, quality of care indicators, including process and intermediate outcomes were explored by SEP categories (1-10), determined according to residential addresses.

Results:

DM prevalence in Israeli adults in 2017 was 9.7%, showing a strong SEP gradient, with higher prevalence in individuals of lower SEP. No SEP disparities were observed in process indicators with overall rates of documentation of hemoglobin A1c (HbA1c) of 90.9%, ophthalmologic examinations of 72.5%, and kidney function examinations of 92.5%. However, strong SEP disparities were observed in the prevalence of uncontrolled diabetes (HbA1c$\geq$9%), with an overall rate of 10.0%, and a 5.4-times higher rate in diabetics of the lowest SES level (23.5%) compared with the highest SEP level (4.3%). A somewhat weaker gradient was seen for the well-control of DM (HbA1c<7-8%, according to duration of disease and age), with an overall rate of 69.7%, and a 1.7 ratio, comparing diabetics of the highest vs the lowest SEP level.

Conclusions:

These findings suggest that access to care does not explain SEP disparities in diabetes control in Israel. There is a need to explore the underlying social, cultural, and possibly the benefits-policy determinants of poor control among individuals of low SEP.

Key messages:

- Wide socioeconomic disparities are present among Israeli adults in diabetes mellitus prevalence and control rates, but not in care processes indicators.
- These findings call for a deeper understanding of the determinants and perhaps a revision of current social benefits policy, which may encourage lack of glycemic control.

Leadership and chronic diseases: a bibliometric review

Miguel José Cabral de Pinho

M Cabral[1], *G Daminani*[2,3]
[1]Public Health Unit António Luz, ACES Amadora, Amadora, Portugal
[2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy
[3]Università Cattolica del Sacro Cuore, Rome, Italy
Contact: miguelcabralpinho@gmail.com

Background:

Leadership and chronic diseases are two frequent topics in current public health discussions. We performed a bibliometric analysis to study what interactions exist between these two themes. This study allows an insight on what is being published and also identifies potential gaps that need to be addressed.

Methods:

We have reviewed all the titles and abstracts of articles available at PUBMED with the MESH terms 'Leadership' and 'Chronic Disease'. We collected information about the authors, year, journal and type of publication and country where the study was done. We have also done a qualitative analysis on the themes addressed.

Results:

We have found 171 entries, of witch 85 (49,7%) referred to apparent peer reviewed studies in English. All other publications referred to editorials, commentaries or the PUBMED entry did not allow for greater clarification. From 1998 the publication of articles became regular, with a peak of 14 articles published in 2014. The average of authors per publication was 3,19. The most frequent country involved was the USA (62), follow by the UK (14), Canada (11) and Australia (10). 128 publications were identified, of which BMC Health Serv Res was the one with the highest number of articles included (5). There was some form of a call for greater leadership from nurses in 22 articles. We also highlight 5 articles that called for a greater role of pastors and religious communities in this field.

Conclusions:

Despite the perception of being common topics, there is still a low rate of publication of studies in the field of leadership and chronic diseases. There is a predominance of articles from the USA. There was not a predominant publication in this field. Despite doctors being typically seen as the leaders within the health field, the articles included seem to point to a trend in calling for a bigger leadership role of other actors, such as nurses.

Key messages:

- There is a need for more research in the field of leadership in chronic diseases.
- There seems to be a trend calling for greater leadership in the field from non-physician actors.

Factors associated with patient activation in a Turkish population with diabetes and/or hypertension

Sibel Sakarya

S Sakarya[1], *E Kulak*[2], *S Gorcin Karaketir*[2], *E Dogan*[2], *M Akman*[3], *S Cifcili*[3], *ED Gunes*[4], *L Ormeci*[5]
[1]Public Health, Koç University School of Medicine, Sarıyer, Istanbul, Turkey
[2]Public Health, Marmara University School of Medicine, Maltepe, Istanbul, Turkey
[3]Family Medicine, Marmara University School of Medicine, Maltepe, Istanbul, Turkey
[4]Business Administration, Koç University College of Administrative Sciences and Economics, Sarıyer, Istanbul, Turkey
[5]Industrial Engineering, Koç University College of Engineering, Sarıyer, Istanbul, Turkey
Contact: ssakarya@ku.edu.tr

Background:

Patient activation (PA), which is known to improve health outcomes, describes the knowledge, skills and confidence a person has in managing their own health care. We investigated the extent of PA and associated factors in adults with diabetes (DM) and/or hypertension (HT). This study is the first in Turkey evaluating PA, using the Patient Activation Measure (PAM) scale. The results of the study provide practitioners with information on the characteristics of patients who need support to increase their activation.

Methods:

We conducted this cross-sectional study in 14 Family Health Centers in Istanbul. The participants were DM and/or HT patients. A questionnaire including the PAM, questions on patient characteristics, life style behaviors, healthcare utilization and health status was applied to 431 patients. Based on PAM score, patients were classified into two activation levels: level 1-2 (poor activation) and level 3-4 (good activation). $\chi2$, t-test and logistic regression (LR) analysis were used. LR analysis was performed for all participants and for women and men separately.

Results:

Of 431 patients (mean age: 63.6), 65% were women; 45% had a poor activation level (PAL). Based on LR analysis; low socioeconomic status (SES) (OR = 1.6; 95% CI:1.01-2.5), being illiterate (OR = 3.9, 95% CI: 1.5-10.7), being primary school graduate (OR = 2.1, 95% CI:1.1-4.2), lack of adult vaccination (OR = 1.9, 95% CI:1.1-3.1), higher BMI (OR = 1.1, 95% CI: 1.09-1.13) and worse self-reported health (OR = 1.2, 95% CI: 1.1-1.3) were factors associated with low PAL. The latter was associated with low PAL for both sexes; high BMI was an associated factor only among women, while low SES and lack of vaccination were factors only in men.

Conclusions:

Almost half of the patients had low activation level in our sample. Associated factors may serve as the basis for the development of interventions needed to enhance activation for patients with DM/HT.

Key messages:

- Low patient activation is associated with low level of education, low SES, high BMI, lack of vaccination and worse self-reported health. The factors associated with patient activation vary by gender.
- A qualitative study with patients having different levels of activation would be useful to understand the underlying motivations.

Participatory approach in developing the long-term care strategy in Slovakia

Zuzana Katreniakova

Z Katreniakova[1,2], *M Levyova*[3], *M Giertl*[4], *I Nagyova*[1,2]
[1]Department of Social and Behavioural Medicine, Faculty of Medicine, PJ Safarik University, Kosice, Slovakia
[2]Slovak Public Health Association (SAVEZ), Kosice, Slovakia
[3]Association for the Patients' Rights Protection in the SR (AOPP), Bratislava, Slovakia
[4]Ministry of Interior of the SR (USV ROS), Bratislava, Slovakia
Contact: zuzana.katreniakova@upjs.sk

Issue/problem:

In Slovak Republic (SR) old-age dependency will rise rapidly in the near future and will more than double in the next 15 years. This profound demographic changes will require restructuring of health and social care systems with more people working in the long-term care (LTC) sector and most likely a higher level of public spending to cover the growing LTC needs.

Description of the problem:

Providing LTC in Slovakia has many problem areas. It is governed by several acts and regulations, which are not always linked and sometimes do not cover the situation entirely. There is not coordinated and integrated LTC model implemented and the distribution of the roles between the health and social care systems is lacking.

Results:

Since 2017 a policy dialog between the key stakeholders - the Ministry of Health of the SR; the Ministry of Labour, Social Affairs and Family of the SR; and civic societies led by the Association for the Patients' Rights Protection has been in place with aim to improve the current LTC Strategy Proposal. Online survey was carried out in May - June 2018, which brought deeper insights into the needs regarding demand and supply, and uncovered the main limitations of the current LTC system, e.g. insufficient capacity of LTC beds or a malfunctioning information system. This was followed by six workshops for professional and lay public, organised between February and March 2019 with aim to collect further evidence on regional level.

Lessons:

The LTC Strategy Proposal development is one of 12 pilot projects within the national project - Promoting partnership and dialogue on participatory public policy making in SR. The initiative takes into account the needs and demands of LTC target groups and will serve as a starting point for further action in this area. [Grant Support: APVV-15-0719].

Key messages:

- In Slovakia, a complex solution of long-term care issues is essential.
- Developing the LTC Strategy Proposal through participatory approach is an important starting point for future action.

Rising prevalence of diabetes: evidence from the national registry in North Macedonia

Aleksandra Stamenova

A Stamenova[1], *G Stevanovski*[2], *M Spasovski*[1]
[1]Institute of Social Medicine, Faculty of Medicine, University Ss. Cyril and Methodius, Skopje, Macedonia
[2]Institute of Pathophysiology and Nuclear Medicine, Faculty of Medicine, University Ss. Cyril and Methodius, Skopje, Macedonia
Contact: stamenovaaleksandra@outlook.com

Background:

Disease reporting and data collection are key tools for the health care systems in order to identify opportunities to address burden of diseases. The country's diabetes patients register was the first registry to be integrated with the e-health system in North Macedonia in 2017. We aimed to estimate type 2 diabetes mellitus prevalence and effectiveness of diabetes control as one of the proposed national priorities in tackling the non-communicable diseases.

Methods:

Cross-sectional descriptive study was conducted on patients entered in the National Diabetes Register in 2017/2018. Patients' socio-demographic and anthropometric characteristics in association with diabetes' complications and outcomes were determined by Pearson correlation coefficient ($P < 0.0001$, 95% CI).

Results:

This study identified a total of 35541 patients with a diagnosis of diabetes, out of which 32888 with type 2. This corresponds to a prevalence rate of 1583.9 per 100,000 population. The prevalence increased with age (65+) and was higher among females than males (56.8% vs. 43.2%). Over 80% of type 2 patients were overweight out of which 34.5% obese (BMI>30kg/m2). Diabetic retinopathy is reported as first diagnosed complication in diabetic patients, followed by neuropathies and vascular complications. Patient's low level of education and higher BMI were associated with increased number of early and late-onset complications.

Conclusions:

Evidence accumulating suggests high burden of complications in type 2 diabetic patients, indicating that the patients understanding of diabetes care, treatment adherence and healthy lifestyle are important topics to be address by health professionals in order to avoid complications and premature deaths in people with diabetes.

Key messages:

- Integrated reporting of non-communicable diseases and risk factors is needed to complete current information gaps, from completeness of data to quality and comparability.
- The action plan for chronic diseases should specifically address diabetes control, as most of the patients with diabetes have high prevalence of comorbidities, complications and unfortunate outcomes.

Clustering & trajectories of multimorbidity across the lifecourse: a 70 year birth cohort study

Amal Khanolkar

A R Khanolkar[1,2], *P Patalay*[1]
[1]MRC Unit for Lifelong Health & Ageing, University College London, London, UK
[2]Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden
Contact: a.khanolkar@ucl.ac.uk

Background:

Multimorbidity ($\geq$2 chronic diseases) is increasingly prevalent in ageing populations and presents a public health challenge in successful disease management. Most evidence for multimorbidity at different ages comes from cross-sectional data, hindering understanding the extent and types of multimorbidity across the lifecourse, how they develop and associated risk factors. The aim of this study is to investigate the clustering and patterning of multimorbidity over the lifecourse using one of the longest running national birth cohort studies.

Methods:

This ongoing study is based on the National Survey of Health & Development (NSHD), a birth cohort study following 5,362 individuals born in 1946 with detailed sociodemographic and clinical data collected from 22 waves across the lifecourse till date. This study will investigate the trajectories and clustering of 24 diseases (physical and mental health) and potential differences by sex and socioeconomic status using mixed-effects linear spline modelling.

Results:

Preliminary analyses indicate that as expected, the rates of many conditions increase with age (e.g. 13% obese at age 43 to 31% at age 69), increasing the likelihood of individuals suffering from multiple conditions with age. At age 63, 73% with diabetes had hypertension, increasing to 85% with hypertension at age 69. We will estimate longitudinal trajectories of multimorbidity for individuals and whether the age of onset and rate of accumulation vary by sex, life-period and SES. Given the longitudinal nature of the data, we will investigate the extent to which multimorbidity earlier in the lifecourse predicts the rate of further multimorbidity later in the lifecourse.

Conclusions:

Understanding patterning and trajectories of multimorbidity over the lifecourse and associated inequalities will better inform health care provision planning including appropriate window periods for intervention, specifically for the disadvantaged at higher risk of high multimorbidity.

Key messages:

- This is the first study to investigate trajectories of multimorbidity with data from birth to old age.
- Understanding how early life factors predict later life multimorbidity will better inform healthcare planning.

Evaluating the effectiveness of a screening program for cardiovascular diseases in Kazakhstan

Vitaliy Koikov

Z Bekbergenova[1,2], *G Derbissalina*[1], *A Umbetzhanova*[1,2], *V Koikov*[2], *G Bedelbayeva*[3]
[1]NCJSC ''Astana Medical University'', Astana, Kazakhstan
[2]RSE on the REM, Astana, Kazakhstan
[3]NCJC, Almaty, Kazakhstan
Contact: vitaliy.koikov@gmail.com

Background:

Cardiovascular diseases (CVD) occupy leading positions in the mortality of the Republic of Kazakhstan (RK). In RK CVD screening is performed with 40-years of age. Objectives: to evaluate the effectiveness of screening over time.

Methods:

We conducted a survey of 121 patients with CVD, identified on screening.

Results:

The average age patients in survey-54.3 [95% CI: 52.64;55.96], of which 38% are men and 62%-women. Fact smoking mark 64 persons (52±8), alcohol-(37.2±11.6), family history-66 (54.5±8.1) daily physical activity-34 person (28.1±14.3). Middle systolic blood pressure (BP) is 144.3 [95% CI: 141.61;146.99] and diastolic BP 90.2 [95% CI: 89.02;91.38] mm.Hg. Most of the respondents have different degrees of obesity. The average BMI is 31.8 [95% CI: 30.93;32.67]. The average waist size is 89.1 [95% CI: 86.88;91.52], with the waist size of women over 80 cm (91.9 [89.03;94.77] and the waist size of men 86.1 [82.31; 89.89]. Mean values for total cholesterol of 5.9 [95% CI: 5.85;5.95]. To evaluate the effect of various factors on the increase in BP, we calculated the analysis of variance. According to our calculations, gender does not affect BP, however, age, BMI and waist size affect.

We interviewed patients for complaints, analyzed outpatient cards, a check-up journal: chest pains or interruptions in the heart during exercise are noted by 25 people (20.7±17.5), improvement of the subjective state-29 (24±15.9), regularly receive basic therapy-59 (48.8±9.1), call the ambulance team-43 (35.5±12), are urgently hospitalized for a year-31 (25.6±15.2) and 7 person participate in the school of CVD. There is a statistically significant relationship between gender and smoking, gender and alcohol, gender and regular intake of basic therapy at a significance level of $p < 0.05$.

Conclusions:

Identifying the low effectiveness of CVD screening over time requires the revision of a comprehensive training program for doctors-nurses and the public.

Key messages:

- Patients in Kazakhstan generally do not change their lifestyle after screening for a disease.
- The effectiveness of the screening depends on the teamwork of the doctor, nurse and patient.

Metabolic complications of obesity

Ramla Mizouri

R Mizouri[1], *M Khiari*[1], *F Boukhayatia*[1], *K Ben Naceur*[1], *R Ben Othman*[1], *F Mahjoub*[1], *O Berriche*[1], *H Jamoussi*[1]
[1]Service A, National Institute of Nutrition in Tunis, Tunis, Tunisia
Contact: mizouriramla@gmail.com

Background:

Obesity, through its numerous complications, influences the functional and vital prognosis, especially in situations of massive or morbid obesity. The aim of our study was to study the metabolic complications associated with obesity.

Methods:

This was a descriptive cross-sectional study carried out in the first half of 2018 involving 100 obese patients attending the Obesity Unit of the National Institute of Nutrition in Tunis. Each patient received a complete clinical examination with a standard biological assessment. Obesity is defined by a body mass index $\geq$ 30 Kg / m2.

Results:

The average age of our patients was 45.08 ± 13.9 years with a female predominance of 88%. The average weight was 103.76 ± 17.9 Kg. The average BMI was 38.95 ± 5.72 Kg / m2. The average waist circumference was 123.88 ± 13.13 cm and the average fat mass was 45.98 ± 12.22 kg. Twenty percent of our population was diabetic with an average duration of progression of 6.6. ± 4.04 years. The prevalence of dyslipidemia was high in morbidly obese patients with a rate of 18.6% compared to moderate to severe obesity at 6.4%. Arterial hypertension was noted in 33% of our population. The presence of moderate sleep apnea syndrome was noted in 31.3% of cases. Hyperuricemia was found in 8.6% of cases. Rheumatologic complications were marked by gonalgia in 26% of cases and low back pain in 6.8% of our patients.

Conclusions:

Screening for complications related to obesity is necessary and essential for the comprehensive care of the obese person. Their treatment must be specific and it should not be limited to weight loss.

Key messages:

- Obesity.
- Metabolic complications.

Validation of a national algorithm for diabetes screening

Giagkos Lavranos

G Lavranos[1], *C Chrysostomou*[1], *M Leonidou*[1], *M Prodromou*[1]
[1]European University Cyprus, Aglantzia, Cyprus
Contact: G.Lavranos@external.euc.ac.cy

Background:
The continuing upward trend in diabetes diagnosis across the world has led governments to adopt new treatment programs. According to the International Federation for Diabetes (2017) Europe and in its Member States spent from 10% to 20% of healthcare costs, for diabetes. The purpose of this study is to assess the feasibility of an algorithm to identify both the regulatory needs of diabetic individuals and to screen for undiagnosed individuals in the community.

Methods:
The population sample consisted of 2100 people. The survey was conducted in two phases over the period 2017-2018. In the first phase we identified the 188 already diagnosed people with diabetes who were asked to answer a questionnaire comparing their current standard of care to NICE indicators. In the second phase, the remaining 1912 non-diabetic patients were asked to answer the Findrisk questionnaire. Those who were classified as high risk and very high risk were selected and referred to a clinical laboratory where they were subjected to a glucose curve to detect any diagnosis.

Results:
The diabetes prevalence at the onset of the study was 9% (188/2100 people). Fifty-two new incidents were diagnosed. Thirty-six new cases were diagnosed by randomized glucose values after triple check and symptomatic diabetes symptoms consistent with the World Health Organization's recommendations on diabetes diagnosis. Sixteen new cases were diagnosed via OGTT. The prevalence of diabetes at the end of the survey reached 11.4% (240/2,100 people)..

Conclusions:
It has been found that one person in every forty in the general population suffers from diabetes without been yet diagnosed. Deviations from international diabetes standards have been observed. A new diabetes strategy should be implemented in the future, allowing the catholic implementation of the Findrisk Diabetes Prevention tool every ten years.

Key messages:
- Despite existing guidelines and recommendations, very few diabetic patients fulfill NICE follow up criteria.
- FINDRISK and OGTT can be used as part of a cost-effective national diabetes screening algorithm.

Breast Cancer burden in Tunisia: situation in 2017 and projections by 2030

Amal Cherif

A Cherif[1], *S Dhaouadi*[1], *M Osman*[1], *M Hsairi*[1]
[1]Epidemiolgy and Public Health, Salah Azaiez Institute, Tunis, Tunisia
Contact: amalcherif206@gmail.com

Introduction:
Despite advances in diagnostic and treatment of cancer, burden of this disease is increasing worldwide. Breast Cancer is one of the leading cancers and major causes of death among female worldwide. The aim of this study was to describe the breast cancer burden in Tunisia in terms of disability adjusted life years (DALY) in 2017 and to perform projections by 2030.

Methods:
DALYs for cancer are the sum of years of potential life lost due to premature mortality (Years Life Lost (YLL) and the years lived with disability (YLD). We used epidemiological data (incidence rate, death rate, DALY, YLL and YLD) estimated by the Institute for Health Metrics and Evaluation (IHME). Demographic data were provided by the National institute of statistics. The projection of DALYs for breast cancer through 2030 was performed by a Poisson Regression analysis with Age -Period -Cohort (APC) using SPSS software while using IHME estimated data for the period 1990-2017.

Results:
In 2017, breast cancer incidence and mortality rate among females in Tunisia were 50.17/100000 persons years and 14.04/100000 persons years respectively. Breast cancer DALY values were 25145 (438 /100000 persons years). The percentage of YLL in DALYS was 92.4%. Without effective interventions, the number of DALYs due to breast cancer would reach 40071 in 2030 with a standardized rate of 507/100000 persons years (IC 95% = [501/100000 to 514/100000]. The number of YLL predicted will attain 36457 with a standardized rate of 461/100000 persons years.

Conclusions:
The burden of breast cancer among Tunisian women in 2017 is relatively high mainly due to the lack of screening program. There is an urgent need of a strong plan of early detection and appropriate care.

Key messages:
- Burden of breast cancer among women in 2017 is high and will rise in 2030.
- Renforcing screening program is urgent.

Current and future burden of prostate cancer in Tunisia projections to 2030

Amal Cherif

A Cherif[1], *S Dhaouadi*[1], *M Osman*[1], *M Hsairi*[1]
[1]Epidemiolgy, Salah Azaiez Institute, Tunis, Tunisia
Contact: amalcherif206@gmail.com

Introduction:
Prostate Cancer is the second most common cancer among men worldwide. Current and future estimates on the burden of cancer are needed. The aim of this study was to assess prostate cancer burden in Tunisia in terms of disability adjusted life years (DALY) in 2017 and to perform projections by 2030.

Methods:
DALYs for cancer are the sum of years of potential life lost due to premature mortality (Years Life Lost YLL) and the years lived with disability (YLD). Estimated data related to Burden of disease (Incidence rate, death rate, DALY, YLL and YLD)are obtained by the Institute for Health Metrics and Evaluation (IHME). Demographic data were provided by the National institute of statistics. The projection of DALYs for prostate cancer through 2030 was performed by a Poisson Regression analysis with Age -Period -Cohort (APC) using SPSS software, while using IHME estimated data for the period 1990-2017.

Results:
In 2017, prostate cancer incidence rate and mortality rates among males in Tunisia were 24.17/100000 persons years and 7.08/100000 persons years respectively. Prostate cancer DALY values were 6548 (114 /100000). The number of YLLs was 5712 with a higher contribution of YLL in DALYS (87.2%). Without effective interventions, the number of DALYs due to prostate cancer would reach 10105 in 2030 with a standardized rate of 113/100000 persons years (IC 95% = [110/100000 to 116/100000].

Conclusions:
The burden of prostate cancer in Tunisia in 2017 is relatively high and will still rising until 2030. This highlights the urgent need to focus resources on disease prevention and in the improvement of treatment.

Key messages:
- The burden of prostate cancer is high in Tunisia in 2017.
- Need to focus ressources on disease prevention and in the improvement of treatment.

Lung Cancer burden of disease in The Northern Tunisia

Amal Cherif

A Cherif[1], *S Dhaouadi*[1], *M Osman*[1], *M Hsairi*[1]
[1]Epidemiolgy, Salah Azaiez, Tunis, Tunisia
Contact: amalcherif206@gmail.com

Introduction:
Lung Cancer is one of the leading cancers and major causes of death among men worldwide. Current estimates on the burden of cancer are needed to plan and evaluate cancer control policies. This study aimed to estimate the lung cancer burden in Northern Tunisia in terms of disability adjusted life years (DALY) from 2007 to 2009.

Methods:

DALYs for cancer are the sum of years of potential life lost due to premature mortality (YLL) and the years of productive life lost due to disability (YLD).We calculated YLL by multiplying the number of deaths by the standard life expectancy at that age using the mortality data of the Global Cancer statistics 2012 (Globocan 2012) and the population data provided by the National institute of Statistics. We used the model life-table West with a life expectancy at birth of 82.5years for women and 80 years for men.YLD were computed by multiplying the number of new cases by the average duration of the disease calculated with the DiSMoDII software. The disability weight employed was 0.917 for lung cancer; a discounting rate of 0.03 was applied. The Incidence data were obtained from the Cancer Registry of the North region of Tunisia 2007-2009.

Results:

The incidence rate of lung cancer in the northern region of Tunisia between 2007 and 2009 was 28.8/100000 persons years for males and 3.1/100000 persons years for females. Lung cancer death rate was 27.8/100000 persons for males and 1.65/100000 persons for females. Lung cancer DALY values were 10404 for males (410/100000) and1251 for females (50/100000). The percentage of YLL in DALYS was 93.3% for males and 51.7 % for females. The highest proportion of YLL was observed for the age group 60-69years for both sexes.

Conclusions:

The burden of lung cancer especially among males is very important. This highlights the importance of promoting the preventive measures such as the Tobacco control including tobacco cessation.

Key messages:

- Burden of lung cancer among male is very high in Tunisia.
- Importance of promoting preventive measures such as tobacco control.

DG Environment, climate and health / Urban health

Organizing the institutional Public Health response to heat under climate change: A scoping review

Melanie Boeckmann

M Boeckmann[1], *G Sanchez Martinez*[2], *V Kendrovski*[3]
[1]Environment and Health, Bielefeld University School of Public Health, Bielefeld, Germany
[2]The UNEP DTU Partnership, Copenhagen, Denmark
[3]WHO European Center for Environment and Health, Bonn, Germany
Contact: boeckmannmelanie@gmail.com

Background:

Extreme heat events are a major health risk, and their intensity and frequency are expected to increase under climate change. Heat health action plans (HHAP) aim to prevent adverse health effects through measures such as warning systems or communication campaigns. This scoping review asked whether the peer-reviewed Public Health literature suggests evidence for good practice governance of HHAP.

Methods:

Databases PubMed and Web of Science were searched using search string combinations of heat, policy, warning system, and related terms. Data was extracted into a pre-defined extraction table based on theory-driven variables related to responsibilities, processes of stakeholder involvement, evaluation and whether good practice advice was provided. Findings were narratively synthesized and gaps in the current knowledge evaluated from a normative standpoint.

Results:

Searches resulted in 6681 hits. After title, abstract and full text screening, 20 articles were assessed, 11 from Europe and 9 from other regions. Findings on structure of governance revealed that the Ministry of Health or Ministry for the Environment leads the development of an adaptation plan or HHAP guidance, while locally Departments of Health most often lead coordination of actions. Interagency cooperation was reported as essential, while in the majority of included studies the public are perceived as recipients of advice and warnings rather than as active stakeholders. Tailoring national guidance to local contexts as well as raising awareness of the plan not only among the public but also among all levels of management was one suggested good practice.

Conclusions:

Few articles explicitly examine the organization of HHAP and no conclusions about whether a specific approach is superior can be drawn from these studies. To adequately protect human health from extreme heat events, an assessment of whether current governance structures are able to provide effective heat health action could be useful.

Key messages:

- The peer-reviewed literature does not provide information on which type of HHAP governance is superior.
- In the absence of a gold standard, it should be assessed what stakeholders and discourses are absent from HHAP governance to ensure vulnerable groups are adequately addressed by HHAP.

Environment and Health: Official knowledge and lay response

Phil Elliott

P Elliott[1], *N Payne*[2]
[1]Research Office, Cheshire and Wirral Partnership NHS Foundation Trust, Chester, UK
[2]School of Health and Related Research, University of Sheffield, Sheffield, UK
Contact: philelliott@nhs.net

Due to its history, Halton, United Kingdom, provides a natural experiment to investigate the divide between lay and official knowledge about environment and deprivation, and how these may influence health choices and outcomes. 55 semi-structured interviews were carried out to assess a cross-section of residents' perceptions and experiences of health, environment and lifestyle, taking a life history approach to examine health over time, and how choices were constructed. These were analysed for themes using a structuration theory approach. Residents' viewpoints were then presented to twenty local public organisation officials, with their own perceptions also discussed. The overall standpoints were very different to those expressed by residents, being based on quantifiable knowledge such as that gained by officially collected statistics. Residents were not only sceptical about the knowledge presented by public health organisations, but valued lay knowledge gained through observation and experience. Official knowledge was interpreted primarily via an analysis of why this knowledge was created rather than an assessment of the knowledge itself. The interpretation was formed by a perception amongst residents that lay fears about pollution were being, at best, downplayed or, at worst, discounted by 'the powers that be' who, in turn, placed faith in checks carried out by other official bodies. Official knowledge represented an expression of vested interests, presented by superordinate and external agents. A feeling of disempowerment co-existed alongside a perception that there was access to a form of truth via observation and experience rather than empirical knowledge. Whereas scientific information was discredited, lay knowledge was seen to be a more reliable guide as it remained free from a perceived bias. A degree of agency could be exercised perhaps only in this perception of 'pure', if unprovable, knowledge.

Key messages:

- Formulation of official knowledge and reception of issued messages by lay residents in an area of high deprivation and compromised environment.
- Factors influencing perception, and adoption, of health messages which may impact on health and well-being in a local population.

Citizens' perceptions of the health-related neighbourhood environment in Limassol, Cyprus

Nicos Middleton

D Kleopa[1,2], *A Panayiotou*[2], *C Kouta*[1], *N Middleton*[1,2]
[1]Department of Nursing, School of Health Sciences, Cyprus University of Technology, Limassol, Cyprus
[2]Cyprus Institute for Environmental and Public Health, Cyprus University of Technology, Limassol, Cyprus
Contact: nicos.middleton@cut.ac.cy

Background:

''Place'' can impact on health and quality of life. There is a growing interest in neighbourhood audits. In the context of developing the CyNOTes audit tool, a residents' perception of the neighbourhood environment survey was performed.

Methods:

A systematic random sample of ten adult residents (N = 150) across a stratified sample of fifteen neighbourhoods according to educational attainment as per census data responded to the ''Place Standard'' tool which assesses 14 aspects of the physical, built and social neighbourhood environment. Neighbourhoods were also audited using the 126-item CyNOTes.

Results:

Three in four participants were home owners and lived in the neighbourhood for over 10 years. With the exception of ''identity and sense of belonging'' (M = 5.8, SD = 2.0) and ''opportunities for social interaction'' (M = 5.3, SD = 2.1), physical and built aspects of the environment were rated close to the middle point on a scale 1: large to 7: little room for improvement. ''Parks, playgrounds and green space'' and ''garbage, animal droppings and other physical disorder'' were the most commonly mentioned priorities for action in the free text by one in three participants. The lowest score was recorded for ''influence and sense of control'' (M = 3.4, SD = 2.4). While on a 1-10 subjective perception of neighbourhood position, residents in lower education neighbourhoods gave a rating of 6.6 on average compared to 8.1 in the higher group, they tended to rate aspects of their neighbourhood more favourably. Even though the audit revealed a systematic pattern of less favourable conditions along the socio-economic continuum, the perception survey revealed a U-pattern with residents in the middle category more likely to give less favourable ratings.

Conclusions:

The extent to which perceptions surveys may be affected by differential expectations across social groups is not clear. Neighborhood audits provide supplementary profiles of ''place'' independent of the perceptions of residents.

Key messages:

- Based on the Place Standard tool, Limassol residents' rate social aspects of their neighbourhood environment more favourably than aspects of the built and physical environment.
- Neighbourhood observed-based audits, independent of residents' perceptions surveys can supplement each other in city health profiling.

''Is anyone walking in our neighborhoods?'': Citizens' experience of the neighbourhood environment

Nicos Middleton

N Middleton[1], *D Kleopa*[1,2], *A Panayiotou*[2], *C Kouta*[1]
[1]Department of Nursing, School of Health Sciences, Cyprus University of Technology, Limassol, Cyprus
[2]Cyprus Institute for Environmental and Public Health, Cyprus University of Technology, Limassol, Cyprus
Contact: nicos.middleton@cut.ac.cy

Background:

Several generic or feature-specific neighbourhood audit tools have been developed in recent years. In the context of developing the Cyprus Neighbourhood Observation Tool for auditing urban environments (CyNOTes), a virtual ethnographic study of citizens' perceptions of their neighbourhood environment was performed.

Methods:

The municipality and mayor's Facebook were reviewed for posts related to neighbourhood environment over a 12-month period (e.g. regeneration projects). Comments were content analysed using a deductive as well as an inductive approach to gain an in-depth understanding of citizens' perceptions of neighbourhood environment.

Results:

348 comments to 27 relevant posts were identified. The unit of analysis was sentences or short phrases and 289 CMU were identified. The central theme was ''Citizens' voice''. Six themes and several sub-themes emerged. ''Comparisons'' to contrast the differing conditions between high-profile locations versus ''left out'' residential neighbourhoods (''Yes, the city centre, the waterfront is a jewel, what about the neighborhoods?'') or to compare their experience to ''another place-another time''. They express ''Mixed feelings'' ranging from ''hope'' to ''disbelief'' about proposed actions. Citizens are referring to ''Consequences'' of neighbourhood adverse environment on ''Quality of Life'' or ''Local ecomomy and housing'' and identify ''Causes'' in ''Money and Power'' or ''Lack of vision and planning''. They are placing ''Responsibility'' in both ''Authorities' inaction'' as well as ''Everyone's role''. ''Suggestions'' included measures related to ''Law and Order'' as well as ''Citizens' participation''.

Conclusions:

Citizens voice their experiences of the neighbourhood environment lack of influence and control and demand for more involvement in decision-making. They blame authorities for neighbourhood problems but also recognize the lack of individual responsibility, suggesting policing and punitive measures and stronger collective action.

Key messages:

- A virtual ethnographic study of citizens' comments on social media offers an in-depth understanding of the neighbourhood experience.
- Citizens want to have a ''voice'' to express their concerns about neighbourhood problems as well as to participate in decision-making.

Identifying barriers to organizational health literacy in public health departments in Germany

Anika Mehlis

A Mehlis[1], *C Hornberg*[1]
[1]AG 7/ Fakultät für Gesundheitswissenschaften, Universität Bielefeld, Bielefeld, Germany
Contact: anika.mehlis@uni-bielefeld.de

Background:

To master challenges to their environmental health, people have to have health literacy (HL). At a national and communal level, focus is shifting from individual HL to health care organizations. They have to raise their organizational health literacy (OHL) to help their users to access information and services. In Germany, public health departments are responsible for environmental health at a population level while the environmental administration is responsible for health-related environmental protection. To date, there is no research on the

OHL of public health departments in Germany. Which are the barriers that keep public health organizations from raising their OHL as well as from making better use of possible synergies with the environmental administration?

Methods:

The study consisted of interviews with experts from public health (n = 7) and environmental departments (n = 5) at communal (n = 8) up to federal state level (n = 4). Experts were asked for their insight on barriers for OHL as well as for cross-sector collaboration. They were selected for a wide range in socioeconomic factors and administrative levels. The interviews were recorded between 10/2018-04/2019. After transcription the anonymized interviews underwent qualitative content analysis.

Results:

In twelve interviews 10.4 h of audio were recorded. Content analysis revealed 13 barriers for OHL. Several of those had been described for hospitals before while others, like low responsiveness to the needs of the public, were unknown so far. Preliminary results also indicated several barriers for cross-sectoral cooperation as well as recommendations to overcome said barriers.

Conclusions:

Interviews with public health and environmental administrative organizations turned up 13 barriers that keep them from raising their OHL. Implementing preliminary recommendations could result in better cooperation, in higher OHL, higher environmental health and therefore contribute to public health in the general population.

Key messages:

- Interviews with experts from public health and environmental administrative organizations in Germany turned up barriers that keep them from raising both their OHL and cross-sectoral cooperation.
- Implementing preliminary recommendations could result in higher OHL of public health departments and higher environmental health of the general public and thus contribute greatly to public health.

Associations of environmental variables with different types of stroke

Vidmantas Vaiciulis

V Vaiciulis[1], J Vencloviene[2,3], R Radisauskas[1,2], D Kranciukaite-Butylkiniene[2,4], A Tamosiunas[2,5], D Rastenyte[6]
[1]Department of Environmental and Occupational Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania
[2]Institute of Cardiology, Lithuanian University of Health Sciences, Kaunas, Lithuania
[3]Department of Environmental Sciences, Vytautas Magnus University, Kaunas, Lithuania
[4]Department of Family Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania
[5]Department of Preventive Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania
[6]Department of Neurology, Lithuanian University of Health Sciences, Kaunas, Lithuania
Contact: vidmantas85@gmail.com

Background:

Air temperature (T) and atmospheric pressure (AP) are among the most closely studied weather variables; increases, decreases, and fluctuations in both have been significantly linked to numerous stroke subtypes. We decided to detect the association between daily numbers of ischaemic stroke (IS) and haemorrhagic stroke (HS) and daily North Atlantic Oscillation (NAO) and Arctic Oscillation (AO) indices and monthly indices of Quasi-Biennal Oscillation (QBO).

Methods:

The study was conducted in Kaunas city from 2000 to 2010. Kaunas stroke register presented daily numbers of IS, subarachnoid haemorrhages (SAH), and intracerebral haemorrhages (ICH). We evaluated the association between these types of stroke and NAO, AO, and QBO indices (NAOI, AOI, and QBOI) by applying Poisson regression, adjusting for month and other weather variables.

Results:

During the study period, we analysed 3,992 cases (2,205 men and 1,787 women) with stroke. IS composed 3,199 (80.1%), ICH 533 (13.4%), and SAH - 260 (6.5%). A change in mean daily atmospheric pressure (AP) of >3.9 hPa and QBOI <-27 were associated with the risk of SAH (RRs with 95% CI were, respectively, 1.54 (1.18-2.03), and 1.68 (1.06-2.66)). The risk of HS was associated with daily increases in AP and QBOI <8.37 ($p<0.05$). The risk of IS was negatively associated with AOI (RR = 0.97 (0.94-0.99). During November-March, NAOI >0 was associated with HS (RR = 1.29 (1.03-1.62)), and a negative association between NAOI and IS (RR = 0.91 (0.84-0.98)) was found.

Conclusions:

The results of our study provided new evidence that the NAO, AO, and QBO pattern may affect the risk of stroke. The impact of these teleconnection indices is not identical for different types of stroke.

Key messages:

- This abstract is part of publication, which will be published later on.
- In some cases, environmental impact is not essential, but quite often determines the course of various diseases, especially of the circulatory system.

Socioeconomic inequalities in cognitive performance among early ageing people: The Constances cohort

Noémie Letellier

N Letellier[1], I Carrière[1], E Cadot[2], L Berkman[3], M Goldberg[4,5], M Zins[4,5,6], C Berr[1,7]
[1]U1061, INSERM, Montpellier University, France

[3]Harvard Center for Population and Development Studies, Harvard University, Cambridge, USA
[4]Population-Based Epidemiological Cohorts Research Un, INSERM, Villejuif, France
[5]Paris Descartes University, Paris University, Paris, France
[6]Aging and chronic diseases, U1168, UVSQ, INSERM, VIMA, Villejuif, France
[7]Memory Research and Resources Center, Department of Neurology, Montpellier University, France
Contact: noemie.letellier.pro@gmail.com

Background:

In spite of the recent awareness of environmental characteristic's impact on brain aging, links between contextual socioeconomic status and cognitive performance (CP) remains unclear. The objective was to investigate the influence of individual and contextual deprivation on cognitive performance in order to better characterize vulnerable population.

Methods:

We performed cross-sectional analyses on 44,762 participants (45-70 y) of the French Constances cohort. Cognitive performance was assessed using a global cognitive score calculated with 6 cognitive tests evaluating global cognitive function, episodic verbal memory, language abilities, and executive functions. Poor performance was defined as a score below or equal to the 25th percentile of the distribution. We approached the deprivation by two validated multidimensional index: at individual level with the EPICES score (deprived if <30.17) and contextual level with the FDep09 score divided in quintile (Q5 being the most deprived). Associations were estimated with multilevel logistic regressions.

Results:

At the individual level, participants more deprived had poorer CP independently to sex, age, education and health status (OR 1.58 [1.48; 1.69]). At the contextual level, the more people lived in deprived environment, the poorer their CP ($p<.0001$), even after adjustment on individual deprivation and other individual characteristics (Q5 vs Q1: OR 1.28 [1.15; 1.41]).

Conclusions:

In this large cohort of early-ageing people, area-based disparities in cognitive impairment were highlighted. A better understanding of the influence of living environment deprivation level on cognitive aging could help to define new strategies in prevention by targeting at-risk populations in interventions studies in order to reduce social health inequalities.

Key messages:

- Our study evidenced a strong socio-economic gradient of cognitive performance identifiable on both individual and contextual level, in a large sample of middle-aged volunteers.
- Independently to individual deprivation and other individual characteristics, living in a deprived environment may be detrimental to the brain health.

Social cohesion as a mechanism behind neighbourhood effects on mental or physical health

Odile Sauzet

S Kress[1], O Razum[1], K A Zolitschka[1], J Breckenkamp[1], O Sauzet[1]
[1]School of Public Health, Bielefeld University, Bielefeld, Germany
Contact: odile.sauzet@uni-bielefeld.de

Background:

The neighbourhood where an individual resides have become a relevant element in the study of health inequalities. While there is substantial evidence that environmental factors affect health, far less evidence of the hypothesised role of social mechanisms in the causal chain between neighbourhood characteristics and health is available.

Methods:

Using data from the longitudinal German SOEP panel, we built measures of perceived neighbourhood characteristics and a measure of social cohesion for participant living in urban areas. Participants were included in a longitudinal cohort of 4 year observation time starting in 2004. Using linear regression models, we tested the role of social cohesion as a mediator between the neighbourhood characteristics at baseline and a health outcome (mental and physical component of the SF-12) at the end of follow-up adjusted for socio-economic variables.

Results:

For the 4 year follow-up 10 665 participants were included. There was no evidence of a mediation effect of our measure of social cohesion between geographical or institutional characteristics and physical health. The effect of social cohesion on mental health was 2.03 ([1.44, 2.59]) and on physical health 1.78 ([1.27, 2.29]). Social cohesion mediated associations between biological (17%, 11%) or built (11%, 14%) characteristics and both physical and mental health and association between institutional characteristics and mental health (7%).

Discussion:

We found evidence for a possible role of social cohesion in the pathway between neighbourhood characteristics and health. Only perceived characteristics have been used in this work and the respective role of objective and subjective measures of neighbourhood characteristics should be further investigated. Moreover, validated measures of social cohesion should be developed.

Key messages:

- The perception of social cohesion mediates the effect of specific perceived characteristics of neighbourhood on mental and physical health.
- Interventions seeking to improve social cohesion in neighbourhoods might have positive consequences on the health and wellbeing of inhabitants.

An ego-centred approach for the evaluation of health inequalities in urban areas

Odile Sauzet

O Sauzet[1], K A Zolitschka[1], J Spallek[2], J Breckenkamp[1], O Razum[1]
[1]School of Public Health, Bielefeld University, Bielefeld, Germany
[2]Department of Public Health, Brandenburg University of Technology Cottbus-Senftenberg, Senftenberg, Germany
Contact: odile.sauzet@uni-bielefeld.de

Background:

Neighbourhood possesses attributes, structural, physical and social, for which pathways to health inequalities could be hypothesized. Hence, neighbourhood is a complex mixture of factors which cannot be simply defined by a delineation on a map, making common definitions of neighbourhood (e.g. administrative borders) problematic. We present a new concept for the evaluation of contextual health inequalities in an urban setting.

Methods:

An ego-centred approach to neighbourhood effects on health allows to establish to what degree the health outcomes of a person are on average correlated to the health outcomes of his/her neighbours. This approach does not necessitate the definition of what a neighbourhood is, or of its boundaries. Using data from the BaBi birth cohort following up 958 mother-child pairs in Bielefeld/Germany we illustrate how the method provides information about the spatial structure of a possible association between unmeasured neighbourhood factors and birthweight. Spatially correlated birthweight indicates a neighbourhood effect on maternal health.

Results:

A parametric model of the correlation structure gives two indicators: a distance after which health outcomes are no longer correlated (practical range), and the strength of correlation (RSV). We modelled birthweight directly and residuals after controlling for (spatially correlated) covariates. After adjusting for the mother's demographics and neighbourhood characteristics, birthweights remained spatially correlated with RSV of 11% and a practical range of 128 m.

Conclusions:

Modelling the spatial correlation of a health outcome provides a measure of the degree of health correlation, thus offering new evidence on the production of health inequalities while incorporating current modelling approaches. Moreover, it measures heterogeneity in a city. This could be used as an indicator for policy makers or town planners to identify areas in need of socioeconomic investment.

Key messages:

- Modelling the spatial correlation of health outcomes is an approach which enable to assess unmeasured neighbourhood effects.
- The health correlation neighbourhood approach helps to investigate the production of health inequalities and to identify urban areas in need of socioeconomic investment.

High resolution data to estimate effects of pollution and temperatures in Italy: The BEEP project

Achille Cernigliaro

A Cernigliaro[1], M Stafoggia[2], C Gariazzo[3], G Viegi[4], F de' Donato[2], S Scondotto[1]
[1]Department of Health Activities and Epidemiological Observatory, Health Autority Sicily Region, Palermo, Italy
[2]Department of Epidemiology, Lazio Regional Health Service, Rome, Italy
[3]Department of Occupational & Environmental Medicine, INAIL, Monteporzio Catone, Italy
[4]Institute of Biomedicine and Molecular Immunology, CNR - IBIM, Palermo, Italy
Contact: achille.cernigliaro@regione.sicilia.it

Introduction:

The BEEP (Big data in Environmental and occupational Epidemiology) project aims to estimate the health effects of several environmental risk factors on the Italian population at municipal level. Specific focus is being devoted to the risk of hospitalizations and mortality at the national level and within the major metropolitan areas and the risk of occupational injuries.

Results:

Particulate matter concentrations and mean air temperatures (1x1km) were estimated using satellite data, land use data and observed data from monitoring networks for the Italian domain for 5 yrs. The short-term effects of PM and air temperature on morbidity and mortality only in Sicily, Lazio, Puglia, Emilia Romagna and Piedmont, were assessed. The preliminary results show: an increased risk of natural mortality, cardiovascular and respiratory hospitalizations in subjects exposed to PM, as well as higher effects in the older age on respiratory admissions in males. Associations were found also in the municipalities of medium and low level of urbanization; a non-linear relationship was found with increased risk of hospitalizations and mortality for high and low temperatures. Effects of heat were observed on respiratory hospital admissions, and effects of cold temperature were found on both cardiovascular and respiratory admissions. Larger effects of heat and cold were estimated in the elderly and in municipalities at a higher urbanization; a larger risk of occupational accidents in the construction industry for hot temperatures and in the transport sector for cold temperatures were evidenced.

Conclusions:

Results of the BEEP project provide innovative findings on the health risks of environmental exposures in both urban and rural settings and provide decision makers with important information for the definition of prevention measures.

Acknowledgement: The BEEP project is supported by INAIL and is described in the website: www.progettobeep.it.

Key messages:

- Using Big Data (environmental and Health) is possible estimate the effect of pollution and temperature on mortality and morbidity among the residents in cities or rural areas.
- Pollutant increase the risk on natural mortality and cardiovascular and respiratory hospitalizations.

Cancer incidence in the vicinity of a waste incineration plant in the Nice area between 2005-2014

Eugènia Mariné Barjoan

E Mariné Barjoan[1], *N Doulet*[1], *A Chaarana*[1], *J Festraëts*[1], *A Viot*[1], *C Géloen*[1], *D Ambrosetti*[2], *N Mounier*[3], *L Bailly*[1], *C Pradier*[1]
[1]Public Health Department, University Hospital, Nice, France
[2]Network, CRISAP PACA, Nice, France
[3]Hematology Service, University Hospital, Nice, France
Contact: marine-barjoan.e@chu-nice.fr

Introduction:

Few studies on cancer incidence have been conducted since the EU 2000/76/EC Waste incineration directive.

Objective:

To measure cancer incidence among the population exposed to atmospheric emissions from the Ariane waste incineration plant near Nice, in the Alpes-Maritimes (AM), compared to the unexposed AM population.

Methods:

All primary invasive cancers and malignant haematological conditions diagnosed among AM residents from 01/01/2005 to 31/12/2014 recorded by the CRISAPPACA Cancer Observatory, public and private hospitals and the ONCOPACA-Corsica Network were included. The exposed area, based on an average dioxin deposition model, was that with a concentration $\geq$4.25ng/m^2/year. Each case was geolocated and assigned to a predefined geographic unit (IRIS): 36 units in the exposed area, 462 in the unexposed area. The adjusted incidence rate, the standardized incidence ratio (SIR) and the Comparative Morbidity Figure (CMF) were calculated for two periods: 2005-2009/2010-2014.

Results:

We recorded 80,865 new cancers in the AM population (1,083,974 residents; 87,462 exposed). For the 2005-2009 period, among exposed women, excess SIR were recorded of acute myeloid leukaemia (SIR = 1.81 [1.03-2.93]), myelodysplastic syndromes (SIR = 2.58 [1.70-3.76]) and myeloma (SIR = 1.64 [1.09-2.37]); in exposed men, of soft tissue sarcomas (SIR = 1.65 [1.05-2, 48]), myeloma (SIR = 2.04 [1.39-2.90]) and lung cancer (SIR = 1.19 [1.03-1.36]). For the 2010-2014 period, there was no excess SIR among women, while among men an excess SIR of myeloma (SIR = 1.76 [1.21-2.47]) and lung cancer (SIR = 1.24 [1.08-1.41]) was observed.

Conclusions:

The higher incidence of myeloma and lung cancer in both periods can be explained by their long latency and by other risk factors. The EU Directive appears to have resulted in limiting atmospheric emissions from the incinerator.

Study funded by the Nice Côte d'Azur Metropolis and with the support of the South-PACA Regional Health Agency.

Key messages:

- Few studies on cancer incidence have been conducted since the EU 2000/76/EC Waste incineration directive.
- The EU Directive appears to have resulted in limiting atmospheric emissions from the incinerator.

Implementation of a nationwide Waterborne disease outbreak surveillance system in France

Stéphanie Rivière

D Mouly[1], *J Pouey*[1], *C Galey*[2], *J Chesneau*[2], *G Jones*[3], *H De Valk*[3]
[1]Dire - Occitanie, Santé Publique France, Toulouse, France
[2]Data, Santé Publique France, Saint-Maurice, France
[3]DMI, Santé Publique France, Saint-Maurice, France
Contact: stephanie.riviere@santepubliquefrance.fr

Issue/Problem:

Waterborne disease outbreaks (WBDOs) remain a public health issue in developed countries, but to date the surveillance of WBDOs in France, mainly based on the voluntary reporting of clusters of acute gastrointestinal infections (AGIs) by general practitioners to health authorities, is characterized by low sensitivity. In this context an integrated and automatized approach to detect WBDO relying on the identification of clusters of medicalized AGI cases sharing a same drinking water networks (DWN) was developed, evaluated in a simulation study and tested in a pilot study by the French National Public Health Agency.

Description of the problem:

Two national big databases support the detection process of potential WBDO: health insurance database for AGI, ministry of health database for drinking water system information. Each detected outbreak has to be investigated regarding environmental criteria during the days before the onset of the outbreak: results on bacterial water monitoring, weather (e.g. heavy rain), technical incidents in the drinking water system (e.g. chlorination breakdown, alarm malfunction). To evaluate the strength of association with drinking water, four levels are proposed based on epidemiological and environmental criteria (strong, probable, possible and undetermined).

Results:

The WBDO surveillance system has been implemented in all french departments since start of 2019 and support by the ministry of health. A web-application, named ''EpiGEH'', was also developed to support the surveillance system. A retrospective study between 2010 and 2017 has detected almost 300 to 550 potential WBDO per year while voluntary reporting identified 2 to 3 WBDO each year during the same period.

Lessons:

Such a specific surveillance system should help health authorities to formulate recommendations regarding the management of drinking water systems and propose appropriate preventive measures, in accordance with the water safety plans.

Key messages:

- The WBDO surveillance system based from health insurance databases constitutes a daily surveillance system of drinking water quality.
- The WBDO surveillance system should drastically improve the detection sensitivity by a factor 100 to 200 compared to voluntary reporting.

Arsenic metabolism and urothelial cancer risk: a systematic review and meta-analysis

Giuseppe Di Martino

G Di Martino[1], *P Di Giovanni*[2], *P Scampoli*[1], *F Meo*[1], *F Cedrone*[1], *G Lucisano*[3], *T Staniscia*[4]
[1]School of Hygiene and Preventive Medicine, ''G. d'Annunzio'' University of Chieti-Pescara, Chieti, Italy

[2] Department of Pharmacy, ''G. d'Annunzio'' University of Chieti-Pescara, Chieti, Italy
[3] Coresearch, Pescara, Italy
[4] Department of Medicine and Ageing Sciences, ''G. d'Annunzio'' University of Chieti-Pescara, Chieti, Italy
Contact: peppinodimartino@hotmail.com

Background:

Arsenic is a toxic metalloid element frequently found in the environment. Chronic arsenic exposure is a critical public health issue in many countries since the identification of arsenic and its compounds as human carcinogens by the World Health Organization. After absorption, inorganic arsenic (iAs) is mainly methylated into monomethylated and dimethylated compounds (MMA, DMA), which are then excreted through the kidney together with unmethylated iAs. Whether the methylation process is to detoxify or potentiate arsenic toxicity, however, remains an ongoing debate. The purpose of this systematic review was to conduct a comprehensive meta-analysis to estimate the association between arsenic exposure and urothelial cancer.

Methods:

10 observational studies met the inclusion criteria and were included in the systematic review. IAs%, MMA% and DMA% were extracted from each paper. Weighted Mean Differences with 95% confidence intervals were defined according to Cases minus Controls. Pooled risk estimates from individual studies were assessed using random effects models. Meta-regression analysis was performed to estimate the extent of urothelial cancer risk as a function of iAs%, MMA% and DMA%.

Results:

Results showed as patients with urothelial cancer presented higher level of urinary iAs% (WMD 2.70, 95%CI 0.64-4.76), MMA% (WMD 2.81, 95%CI 1.43-4.20) and DMA% (WMD-3.44, 95%CI-6.57–0.30).

Conclusions:

These findings suggest that higher level of iAs% and MMA% and lower level of DMA% were associated with an increased risk of urothelial cancer. Additional population based studies are needed to understand the role of arsenic in cancer development. Understanding the meaning of arsenic metabolism could improve the risk assessment of arsenic toxicity and provide a potential tool for disease prediction and prevention.

Key messages:

- Higher level of iAs%, MMA% and DMA% were associated with an increased risk of urothelial cancer.
- Understanding the meaning of arsenic metabolism could improve the risk assessment of arsenic toxicity.

Assessing the use and understanding of the Portuguese Heat–Health Warning System (ÍCARO)

Andreia Leite

A Leite[1,2], AJ Santos[1], S Silva[1], B Nunes[1,2], R Mexia[1], AP Rodrigues[1]
[1] Department of Epidemiology, National Health Institute Dr. Ricardo Jorge, Lisbon, Portugal
[2] Public Health Research Centre, National School of Public Health, Nova University Lisbon, Lisbon, Portugal
Contact: andreiaheitorleite@gmail.com

Background:

Heatwaves can lead to increased mortality. Portugal has a Heat-Health Warning System (HHWS) in place (ÍCARO system). Researchers at the Instituto Ricardo Jorge send a daily report with heat-related mortality forecasts to key stakeholders (e.g. Heat-Health Action Plans (HHAP) staff). HHAP practitioners issue warnings and implement measures to prevent heatwaves-related mortality. ICARO is amongst the recommended data sources to assess risk and issue warnings but its use and understanding is unknown. Therefore, we aimed to assess ÍCARO's use and understanding by key HHAP practitioners.

Methods:

We conducted semi-structured interviews with national and regional HHAP practitioners. Interviews were recorded, transcribed, and analysed using thematic content analysis. Intercoder reliability was applied to a sample of segments from 5 of 6 interviews.

Results:

We conducted 6 interviews with 9 professionals (mean time 52 minutes). We identified 4 categories: Report's content and presentation, Report's reception and communication, ÍCARO and risk assessment, Other issues. Practitioners use ÍCARO and perceived it as very relevant tool. However, they mentioned several questions on its interpretation. Practitioners also felt their questions were not fully answered, given researchers' use of statistical terms. Finally, practitioners referred the need to assess risk at the local level, information not currently provided. We also identified the need for improved communication and report's clarity.

Conclusions:

Our study stresses the need for an integrated collaboration between experts within HHWS and HHAP. Despite ICARO's understanding being challenging, practitioners consider it a relevant tool. Researchers should use less statistical language and clarify ÍCARO interpretation. Practitioners' needs should be considered when developing or revising tools. We are currently implementing some of these recommendations in an attempt to close the gap between researchers and practitioners.

Key messages:

- Portuguese Heat–Health Action Plans practitioners use heat-related mortality forecasts (ICARO) and perceived it as very relevant instrument. However there find ICARO's interpretation challenging.
- Portuguese Heat/Health Action Plans Practitioners' needs should be considered when revising or developing tools, and notes should be added to clarify statistical/technical concepts.

Environmental health risks perceptions: results from cross-sectional surveys in Southeastern France

Aurélie Bocquier

A Bocquier[1,2,3], S Cortaredona[1,2], M Andrieu-Semmel[4], L Dagnet[5], V Pouget[5], S Urban-Boudjelab[4], P Verger[1,2,3]
[1] Aix Marseille Univ, IRD, AP-HM, SSA, VITROME, Marseille, France
[2] IHU-Méditerranée Infection, Marseille, France
[3] ORS PACA, Observatoire Régional de la Santé Provence-Alpes-C, Marseille, France
[4] ARS PACA, Agence Régionale de Santé, Provence-Alpes-Côte d'A, Marseille, France
[5] Région Sud-Provence-Alpes-Côte d'Azur, Marseille, France
Contact: aurelie.bocquier@inserm.fr

Background:

In accordance with commitments made as part as the European conferences on environment and health in the 90s, France has adopted national environmental health plans since 2004. These plans include regional offshoots to take local specificities into account. To guide stakeholders in defining this plan in Southeastern France, studies were carried out to document general population environmental health risks perceptions and practices.

Methods:

Data come from the Southeastern Baromètre santé environnement, random cross-sectional telephone surveys carried out in 2007 and 2017 among the population aged 18-75 years (n = 1415 and 1960 respectively). They focused on people perceptions' about environmental health risks (e.g., air pollution) and actions to reduce them, trust in sources of information, and their practices. We performed descriptive analyses of the 2017 data, and logistic regression models adjusted for sociodemographic variables to test time evolutions.

Results:

In 2017, the main environmental health risks perceived were pesticides, carbon monoxide, and air pollution (over 90% of the participants thought they carry high health risks). As in 2007, over 90 % thought the air quality had been worsening. The most efficient ways to reduce air pollution were the improvement of public transportation, of bike paths and the development of car sharing. Between 2007 and 2017, self-reported use of soft mobility and/or car sharing increased from 54% to 66%; and consumption of organic food increased from 40% to 69%. Participants perceived physicians as the most trustful source of information about environmental health.

Conclusions:

Habitants from Southeastern France are highly concerned by environmental health risks, especially pesticides and air pollution. They call stakeholders to take actions to reduce these risks, but appear to have changed some of their own practices too. These results helped stakeholders to define priorities of the current regional environmental health plan.

Key messages:

- The general population was highly concerned by environmental health risks (especially pesticides and air pollution), and has become aware of the necessity of changing its own practices.
- Such results about the regional population main concerns have been used to define regional priorities for actions.

A mobile device to reduce airborne particulate and prevent surgical site infections

Giulio Alberto Carta

G Messina[1,3], G Spataro[2], L Catarsi[3], MF De Marco[4], A Grasso[4], GA Carta[3], G Cevenini[2]
[1]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[2]Department of Medical Biotechnologies, University of Siena, Siena, Italy
[3]Post Graduate School of Public Health, Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[4]Medical Management, Siena, Italy
Contact: giulio.carta@student.unisi.it

Background:

Surgical Site Infections (SSI) are the second main cause of Hospital Acquired Infections (HAI) in Europe and in the United States (US). In US and Europe hospitals the overall annual medical costs of HAI is about $40 billion and the SSI represent a relevant part of this spending. It is known that air particulate is a carrier of pathogen bacteria. The aim of this study is to verify if a mobile unit for air particle filtering can improve the environmental airborne conditions of an operating room (OR).

Methods:

We carried out a cross sectional study in March 2018 in an Italian University Hospital. A novel mobile device to purify air was tested during surgical procedures. It is provided with: an air decontamination-recirculation system unit; a patented crystalline ultraviolet C reactor; a highly efficient particulate air filtering. The environmental contamination has been monitored in the following phases: I) device off and OR at rest; II) device off and OR in operational; III) device on and OR in operational; IV) device off and OR in operational. We used a particle counter to measure airborne particles of different sizes: 0.3; 0.5; 1.0; 3.0; 5.0; 10 μm. Air samples were withdrawn in four spots of the OR periphery. Wilcoxon rank test was used for the statistical analysis setting the significance level to 95% ($p < 0.05$).

Results:

From phase II (device off) to phase III (device on), there was a reduction of any particulate matter size, ranging from 50% to 73% ($p < 0.05$). When the device has been turned off again (phase IV), particle dimensions of 0.3, 0.5, 1.0 and 3.0 μm were lower in the percentage range of 51-62% ($p < 0,05$). Particle dimensions of 5 and 10 μm were also lower in the range of 56% and 76%, respectively.

Conclusions:

During mobile device operation, the amount of particulate matter remains significantly lower, reducing the probability of SSI.

Key messages:

- Air particulate in surgical room may play a role in preventing Surgical Site Infections.
- The mobile device was able to significantly improve air quality during real operation conditions.

Association between heat waves and number of deaths for old-age in slovenia, from 2013 to 2017

Simona Percic

S Percic[1], T Cegnar[2], A Hojs[1]
[1]National Institute of Public Health, Ljubljana, Slovenia
[2]Slovenian Environment Agency, Ljubljana, Slovenia
Contact: simona.percic@nijz.si

Background:

Heat waves are associated with incresed mortalitiy, especially in old-age population.

Methods:

We estimated relative risks for number of deaths, for the observed diagnoses, sex, and area, as well as 95% confidence intervals and excess deaths associated with heat waves occurring in the years from 2013 to 2017, for population 75+ years old.

Results:

Statistically significant were: in 2014: all causes of deaths (RR = 1.27, CI 1.12-1.44); male, all causes of deaths (RR = 1.27, CI 1.04-1.56); female, all causes of deaths (RR = 1.26, CI 1.08-1.48); all, circulatory system diseases (RR = 1.19, CI 1.01-1.43); female, circulatory system diseases (RR = 1.23, CI 1.01-1.51); rural area (RR = 1.28, CI 1.09-1.51); urban area (RR = 1.35, CI 1.11-1.64); and in 2015: all causes of deaths (RR = 1.28, CI 1.15-1.41); male, all causes of deaths (RR = 1.27, CI 1.08-1.5); female, all causes of deaths (RR = 1.27, CI 1.12-1.45); all, circulatory system diseases (RR = 1.27, CI 1.1-1.48); male, circulatory system diseases (RR = 1.38, CI 1.06-1.79); female, circulatory system diseases (RR = 1.23, CI 1.03-1.47); rural area (RR = 1.31, CI 1.16-1.47). No significant association in 2013, 2016 and 2017 appeared.

Conclusions:

Despite increasing heat load in observed years, we did not notice a statistically significant association between heat waves and the number of deaths in the last observed years 2016 and 2017. The results indirectly show that we are on good way with our public health efforts concerning awareness of Slovenian people about the dangers heat waves bring.

Key messages:

- Heat waves will become more intense, will last longer and will appear more frequent. We must take care after old age population.
- Chronic noncommucating diseaes increase and life expectancy also increases, so the burden of deaths during heat waves is expected to increase too.

Towards a better integration of health in urban development project: from theory to action

Anne Roué-Legall

A Roue-Le Gall[1], C Deloly[1], B Clement[3], C Nassiet[3], J Romagon[1], M-F Thomas[2]
[1]EHESP, Rennes University, CNRS, ARENES - UMR 6051, Rennes, France
[2]EHESP, Rennes University, Inserm, Irset - UMR_S 1085, Rennes, France
[3]Bordeaux Metropole Urban Planning Agency, a'Urba, Bordeaux, France
Contact: anne.roue-legall@ehesp.fr

Background:

Despite a well knowledge about links between urban planning and health, practices' analyze highlights the difficulty to upgrade health into urban planning decisions. To overcome this issue, the EHESP has initiated a specific research dedicated to the development of tools for a better integration of health & wellbeing at different decision-making-level (urban planning & urban development project). The objective of this presentation is to focus on one dedicated research, Isadora project, and to share how the project was carried out to enable the production of an operational tool dedicated to urban planners to better integrate health issues into their practices.

Methods:

The scientific management team mixed various skills from public health, environment and urban planning sectors which makes easier the implementation of two key-principles of research: (i) to adopt a systemic approach to health determinants, (ii) to address urban settings through an integrated approach to public health, environment and sustainable development issues. The implementation of this interdisciplinary and intersectorial project is based on a close collaboration with a national working group composed of various professionals and academics (urban planning, environment, and health). The Isadora project deliverables results from an iterative process between all the stakeholders involved in the project.

Results and conclusions:

First, we will present how we facilitated the working group throughout the deliverables development process and how we overcame the challenges of implementing intersectorality. Then, we will present the operational tool structured around of 15 key sheets with health focus to help professionals to integrate health at each step of an urban development project.

Key messages:

- ISadOrA project aspires to promote an evolution of urban planner's practices in order to achieve a healthy urban development project.
- This ambition requires the translation of concepts into actions.

Evaluating implementation of an Heat-health action plan during 2018 heatwave in Amadora, Portugal

Andreia Leite

A Leite[1,2], *M Cabral*[1], *E Rodrigues*[1], *D Vaz*[1], *E Calé*[1], *AC Silva*[1]
[1]Public Health Unit, Primary Health Care Cluster Amadora, Amadora, Portugal
[2]Public Health Research Centre, National School of Public Health, Nova University Lisbon, Lisbon, Portugal
Contact: andreiaheitorleite@gmail.com

Issue:

Heatwave-health effects are preventable. Heat-health action plans (HHAPs) include preventive measures aimed at protecting population. In Portugal, HHAPs exist since 2004 and have been operationalized at local level. Heatwaves occur infrequently, thus experience with HHAPs is relevant to countries implementing their own HHAPs.

Description:

In the summer of 2018, Amadora (Lisbon, Portugal) issued a warning from the 2nd-6th August (highest level:4th-6th). Before/during the warning we implemented: 1.climatized shelter opened available upon request;2.text messages with recommendations and information on the walk-in clinic services available;3.information to nursing homes regarding available services (walk-in services/shelter);4.contact with individuals receiving home support and identified as vulnerable. Nationwide media publicity of individual protection measures was also ongoing. We aimed at evaluating these HHAP measures. We compared demand of walk-in clinic (primary care) and emergency department with existing capacity, updated during the heatwave. Mortality was analysed using an observed-expected ratio (O/E) of week 32 (following the heatwave) and 95% confidence interval (95%CI) under a Poisson distribution. Expected deaths were the average deaths in week 32 of the previous 4 years (2014-17).

Results:

In the primary care walk-in clinic the demand was ½ of capacity; hospital emergency services demand did not increase. We had no requests for the shelter unit. Regarding mortality, O/E was 1.57 (95%CI:1.12-2.14). These results are preliminary; we are producing more detailed analyses of mortality data.

Lessons:

We have no counterfactual to assess the effect of our HHAP but our results indicate the possibility to reduce heatwaves-mortality further and thus the need for additional measures. We did not observed the expected surge in service demand; the adequacy of supply-based measures is currently under debate. More detailed mortality analysis will provide further insights.

Key messages:

- We implemented several measures during a heatwave in Amadora, Portugal with no increased demand in available health services in the area.
- We detected an increased mortality following the heatwave, suggesting the need to implement further measures.

Neighborhood environment and physical activity among rural Japanese older adults

Kenta Okuyama

K Okuyama[1], *T Abe*[1], *T Nabika*[1,2]
[1]Center for Community-based Healthcare Research and Education, Shimane University, Izumo, Japan
[2]Department of Functional Pathology, Faculty of Medicine, Shimane University, Izumo, Japan
Contact: ko215ok@gmail.com

Background:

Physical inactivity is one of the global health concerns. Rural populations in general tend to be more physically inactive and have higher risk for chronic conditions. Although numerous studies have assessed the association between neighborhood environment and physical activity to implement population level intervention, most are limited to urban adults. This study investigated potential neighborhood environment associated with physical activity for rural older adults in Japan.

Methods:

The study subjects were from Shimane where is a rural-mountainous region in Japan. Those agreed to participate in the Shimane CoHRE study as of baseline (2010) and followed-up after 5 years were included in the analysis (mean age = 71, n = 717). Subjects were asked if they engage in 30 minutes exercise more than twice a week at baseline and follow-up surveys. As a primary exposure, we computed mean land slope within 500 m street network buffer from residential point of each subject by geographic information system. Multiple logistic regression was conducted to estimate the odds of exercise engagement after 5 years by slope categorized in tertile, adjusting for age, BMI, and exercise habit at baseline.

Results:

Significantly higher odds of exercise engagement was observed among those living in the hilly area compared to moderately hilly area after 5 years adjusting for baseline age, BMI, and exercise habit, (Odds ratio (OR): 1.71, 95% Confidence Interval (95%CI): 1.119, 2.616). There was no significant difference of odds between those in flat area and moderately hilly area (OR: 1.137, 95%CI: 0.738, 1.751).

Conclusions:

This finding suggests that people living in hilly neighborhoods are more likely to maintain or start engaging in exercise after 5 years. Considering other potential environmental factors and farming culture within rural areas, future studies should capture various forms of environmental components and physical activity to dissect the mechanism.

Key messages:

- There are limited studies focus on rural older adults.
- Unique geographic feature in rural areas, i.e. hilly neighborhood might be associated with physical activity.

Hillwalking and walk leading motivations, perceived benefits and the role of natural environment

Nora Morocza

Contact: N.Morocza@2016.ljmu.ac.uk

Background:

Promoting the link between human and ecosystem health is crucial for building resilient communities. Hillwalking provides health benefits arising from physical activity and exposure to nature. Furthermore, it is likely to influence environmental knowledge and pro-environmental behaviour through connectedness to nature. This project aimed to explore 1) hillwalking and walk leading motivations and perceived benefits, and 2) the role of the environment and nature connectedness among walk leaders and walking holiday guests.

Methods:

The first study was completed with seventeen volunteer walk leaders and used a mixed methods design: hillwalking interviews, physical activity measurements, location data and the Nature-relatedness scale. The second study involved five group interviews with the total of twenty-five guests on three different walking holidays. The qualitative data from both studies were analysed using a combined thematic and grounded theory approach and the results were merged with the quantitative data to explore the impacts of environmental factors.

Results:

Primary motivations for hillwalking included pleasure, escape from everyday life pressures, to re-charge, being in nature, social inclusion and health. Emerging overarching themes such as balance and adaptation were reported as essential values for walking and were linked to nutritional, physical activity related and environmental aspects of health awareness. The perceived benefits positively impacted on engagement. Connectedness to nature was linked to environmental knowledge and attitudes which manifested in pro-environmental walking behaviour.

Conclusions:

The pleasure arising from several aspects of hillwalking or walk leading was the drive for regular engagement, therefore a primary intrinsic motivation. The results imply that attending group walking holidays has the scope to increase environmental awareness and engagement in outdoor physical activity and could be considered as a promotion tool.

Key messages:

- The findings have the scope to inform future walking promotion programs and encourage long-term engagement by shifting the focus of promotion messages to intrinsic motivational factors.
- The results support that hillwalking can be used as a tool for combined health and environmental awareness promotion.

Environmental noise levels and noise annoyance in Novi Sad, 2012-2016

Marija Jevtic

E Zivadinovic[2], *M Jevtic*[1,2], *N Dragic*[1,2], *S Bijelovic*[1,2]
[1]Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia
[2]Institute of Public Health of Vojvodina, Novi Sad, Serbia
Contact: marija.jevtic@uns.ac.rs

Objective:

Increased noise level represents a significant public health problem in urban environments. The aim of this paper is to examine the annoyance of the population by road traffic noise in the City of Novi Sad.

Methods:

The results of 161 24-hour noise measurements in Novi Sad were analyzed. Measurements were done by Public Health Institute of Vojvodina, according to accredited and standardized national methodology during 2012 - 2016.

Results:

Total noise indicator (Lden) / night noise indicator (Lnight) ranged from 61,1 dB / 50,7 dB in residential, up to 66,3 dB / 58,1 dB in recreation / hospital areas, 68,0 dB / 60,3 dB in city traffic areas and 70,2 dB / 62,7 dB in business and residential areas. Taking into account the results and using methodology prescribed by national regulations, the percentage of highly annoyed population (% HA) was found to be in the range 11-25% during the day, and 6-13% during the night. Using ISO 1996-1:2016, prevalence of a population highly annoyed (PHA) was established to be in the range 9,2-33,9% in residential; 18,4-45,7% in recreation / hospital areas 22,9-50,6 in city traffic; 27,7-55,4% in business and residential areas.

Conclusions:

The results confirm that urban noise seriously disturbs people. It was established that about a half of the population was highly annoyed which poses a serious challenge for public health. The results have social, health and economic importance for the population. Activities to reduce the noise level could also stimulate economic, health, social and community programs for sustainable development aiming to preserve and improve human health.

Acknowledgment: Supported by the Ministry of Education and Science of the Republic of
Serbia - Project ''Biosensing Technologies and Global System for Continuous Research and
Integrated Management'', No.43002

Key messages:

- Continous noise monitoring is important for understanding the impact of noise on human health.
- About a half of the population was highly annoyed by noise, which poses a big challenge for public health in urban areas.

Bridging worlds: community led visual methods amidst climate change related disasters in Australia

Colin Macdougall

C Macdougall[1,2], *L Gibbs*[2]
[1]College of Medicine and Public Health, Flinders University, Adelaide, Australia
[2]Melbourne School of Population and Global Health, University of Melbourne, Melbourne, Australia
Contact: colin.macdougall@flinders.edu.au

Background:

In February 2009 Victorian rural communities were hit by the worst bushfires in Australian history. Immediately we evaluated community groups preparing residents for bushfires. Ten years on, we are one of the few teams to evaluate medium to long term community recovery using multiple methods. As climate change becomes more visible, the frequency and intensity of disasters will increase so communities, governments and service providers need more evidence based strategies and policies. We explore how participant led visual methods provide new knowledge.

Methods:

In study 1 participants in 3 of 7 focus groups in peoples' homes spontaneously brought photos for us to examine before the discussions. In another participants spoke of the importance of photos they took at the time. We returned to the field to interview people in their homes about the meaning and role of photos.

Results:

Participants wanted to inform us-as outsiders-of the awe and enormity of the fires. They created a visual record to communicate with key interest groups and ward off complacity as memories receded. Photos helped them construct timelines and meanings of the intense fires. Crucially, they recorded recovery and rebuilding in both the built and natural environments. Over the next ten years we chronicled stories from community led visual methods of communication, recovery and empowerment. We incorporated into qualitative methods participant led tours of their environments, with visual methods. Visual data collected by communities focused more strongly on the natural environment than researcher led verbal methods.

Conclusions:

Visual sociology changes as technology provides participants in research with increased access to, and control over, visual methods. These changes can rebalance power relations between qualitative researchers and participants and bridge visual and verbal methods; crafting striking stories to influence those Australian policies unresponsive to climate change.

Key messages:

- Technological change enables participants in qualitative research to initiate visual methods to build bridges between them and researchers.
- Community led visual methods provide new types of data useful for theory and knowledge translation.

Facing climate change challenges: the Italian Public Health Residents response

Marco Righini

L Mammana[2,6], *F Catalani*[2,6], *D Di Fonzo*[6], *OV Giannico*[3,6], *RS Miceli*[2,6], *M Righini*[5,6], *S Rivolta*[1,6], *LG Sisti*[4,6], *FG Vaccaro*[6]

[2]Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy
[3]Department of Biomedical Sciences and Human Oncology, University of Bari, Bari, Italy
[4]Institute of Public Health, Section of Hygiene, Catholic University of the Sacred Heart, Rome, Italy
[5]Department of Medicine, University of Udine, Udine, Italy
Working Group Health and Climate Change, Consulta degli Specializzandi, Italian Society of Hygiene, Preventive Medicine and Public Health (SItI), Rome, Italy
Contact: righini.marco@spes.uniud.it

Background:

Climate change (CC) is one of the most important global issues, and exerts a strong impact on public health (PH). Correlation between CC and PH is a matter of concern in the whole scientific community and requires an interdisciplinary approach. Nevertheless, the need to take action on CC sometimes contrasts with national and local policies, involved professionals' training and citizens' education. In order to face these challenges, the Italian network of public health residents ''Consulta Specializzandi'' of the Italian Society of Hygiene, Preventive Medicine and Public Health (SItI) decided to create a specific working group.

Objectives:

Main objectives are education of PH residents and practitioners on CC, argument disclosure among the SItI and creation of interdisciplinary networks to promote and extend group activities. Secondary objective is development of a study to identify the gap between scientific evidence, recommendations and guidelines, and the European, national and local policies, with the aim of promoting bottom-up researches and good practices in CC management.

Results:

The group was created in January 2019; activities started in March. Firstly we defined priorities and work mode. Then we analyzed scientific evidence and promoted self-training on the link between environment and CC and on the impact of CC on individual and public health. Finally, through attendance at workshops and scientific events, we began to train other PH residents and practitioners and started to create networks with other scientific societies, research centers and foreign academies, in order to promote international research, advocacy and disclosure between different institutions regarding the relationship between CC and PH.

Conclusions:

The group has already partially achieved its main objectives, especially increasing awareness and training in CC and related issues. Further activities will permit to strength interdisciplinary networks and to move to secondary objectives.

Key messages:

- CC severely impacts society. Yet there is no widespread feeling of urgency to act towards its causes and consequences. A change in mindset is mandatory, from individual citizens to decision makers.
- PH residents and practitioners must be the main actors in training and education, advocacy, disclosure and network creation in CC research and management.

Healthier breath for all and everywhere – Urban air quality monitoring experience

Marija Jevtic

J Gajic[1], *D Dimovski*[1], *B Vukajlovic*[1], *M Jevtic*[1,2]
[1]Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia
[2]Institute of Public Health of Vojvodina, Novi Sad, Serbia
Contact: marija.jevtic@uns.ac.rs

Issue/problem:

Increasing attention is being paid to air pollution as one of the greatest threats to public and urban health. The WHO's Urban Health Initiative points out the importance of collecting data and mapping the present state of air quality in urban areas. For citizens, such engagement is enabled by the appearance of personal air quality measurement devices that use crowd-sourcing to make measurement results publicly accessible in real time.

Description of the problem:

As a way of contributing to air pollution monitoring in their town, three PhD Public health students conducted over 40 measurements between the start of June and end of August 2018 on various locations in the city of Novi Sad, Serbia. Measurements were performed using AirBeam personal air quality monitoring devices and their results presented as μg/m3 of Particulate Matter 2.5 (PM2.5) and automatically uploaded to the internet using the Air-casting app.

Results:

Measurements conducted in public transportation vehicles returned the rather high average value of 40 μg/m3, where coffee shops and restaurants scored an even higher value of 48,67 μg/m3. The lowest average air pollution levels were registered near the Danube river bank (5.67) and in the parks (6), while the sites near crossroads or in the street showed average air pollution of 8.33 μg/m3.

Residential areas where smoking is present during the day reported 2.5 times higher PM2.5 values than those without smokers (33.8 and 12.78 μg/m3).

Lessons:

Bearing in mind that the air quality is considered as a serious health risk in urban areas, results of this pilot investigation suggest potential health risk for citizens living in urban areas. The negative effects of combustion and smoking on air quality are strongly highlighted, as well as the positive impact of green areas and parks near residential areas.

Key messages:

- Air pollution exposure as a serious health risk in urban areas.
- Crowdsourcing as a way of air quality monitoring has great potential for contributing to public health.

Occupational exposure assessment to per and trichloroethylene in dry cleaning in Sfax city (Tunisia)

Fatma Omrane

F Omrane[1], *M Khadhraoui*[1], *A Abid*[1], *M Mitigui*[1], *B Elleuch*[1], *I Gargouri*[1,2]
[1]Laboratory of Environmental Engineering and EcoTechnology, University of Sfax, Sfax, Tunisia
[2]Medical School, University of Sfax, Sfax, Tunisia
Contact: fatma.omrane@eleve.ehesp.fr

The use of chlorinated solvents in dry cleaning poses risks to human health. The current study is the first in Tunisia and Sfax city that aims to assess the occupational exposure and health risks of perchloroethylene (PCE) and trichloroethylene (TCE) in the dry cleaning industry. TCE was suspected to be used as it is not explicitly banned by law.

We identified dry cleaning facilities by door-to-door canvassing within a 5 Km radius from the city center of Sfax. We found 47 facilities, but only 33 accepted to join our study. Then, we randomly selected 16 facilities where the exposure assessment to these solvents was conducted by indoor air measurements. The exposure levels were compared to occupational exposure limit values (OELV) and toxicological reference values. Then, cancer risks were evaluated.

TCE was detected in all workplaces and their levels are close to the OELV (95% CI of the mean value [40.4-46 mg/m3]). The mean value of PCE concentrations is lower than the fifth of the OELV, but they are quite variable (95% CI of the mean value [5.1-43.4 mg/m3]). The overall results showed that inhalation exposure levels may induce many adverse effects that are probably threatening the occupationally exposed population and even the general one, because of the location of all facilities in residential settings. Among threshold effects, we noted high risks of neurological, renal, developmental and immune effects. As for carcinogenic effects, greatly high cancer risks were noticed if the lifetime exposure would have these average levels; 17 additional cases of kidney, hematologic or liver cancers are expected to occur in populations of 100.

This study is significant for better understanding of the dry cleaning industrial sector in Tunisia and for the progress of future risk assessment studies. Indeed, it responded to many interrogations and suspicions about the qualitative and quantitative exposure conditions and thus the health status of dry cleaning workers in Sfax.

Key messages:

- Our study is the first health risk assessment study of the exposure to chlorinated solvents in dry cleaning in Sfax city. It revealed high levels of trichloroethylene that is a carcinogen to humans.
- The high exposure levels to per and tri-chloroethylene, in dry cleaning in Sfax city, may induce adverse health effects to workers and even the general population due to residential exposure.

Effect of outdoor air pollution on respiratory deseases in the District of Tunis

Aicha Lahchaichi

A Lahchaichi[1], H Bellali[2], C Harizi[2], N Ben Alaya Bouafif[1], K Talmoudi[1], MK Chahed[2]
[1]National Observatory of New and Emerging Diseases, Tunis, Tunisia
[2]Epidemiology and Statistics Department, A Mami Hospital, Ariana, Tunisia
Contact: aicha.hechaichi@gmail.com

Background:

Asthma and Chronic Obstructive Pulmonary Disease (COPD) are the two most common chronic obstructive pulmonary diseases worldwide. The objective of this study was to analyze the relation between the daily levels of air pollution indicators and the number of emergency department visits (EDV) for asthma and COPD exacerbation in the District of Tunis.

Methods:

We conducted a retrospective ecological study. We collected daily morbidity data from the emergency register of Ariana Mami Hospital from 1 January 2007 to 31 December 2014. We investigated the association between daily EDV for asthma or COPD exacerbation and daily concentrations levels of air pollutants by simple Pearson correlation and by binomial negative regression using generalized linear models (GLM).

Results:

For morbidity data, we recorded 19127 EDV for asthma (10771, 56.3%) and COPD exacerbation (8356, 43.7%) between 2007 and 2014. We observed a rising trend in the number of EDV for COPD since 2007 with winter seasonality. Regarding the profile of air pollution in the study region, we have exceeded the thresholds of all standards for PM10, exceeding the Canadian standard for O3. However, no threshold exceeded for NO2 and SO2. In the univariate analysis, there was a positive correlation between the daily number of EDV for asthma and COPD exacerbation and NO2 ambient concentration (r = 0.121, p < 10-3) and O3 level (r = 0.066, P < 10-^{3}). Multivariate analysis showed a significant positive association between the daily number of EDV for asthma and COPD exacerbation and NO2 daily concentration (Adjusted OR = 1.033, CI = [1.011 - 1.055], P < 10-3) with a delayed effect of 10 days for NO2 and 12 days for O3.

Conclusions:

The exacerbation of asthma and COPD was correlated to the NO2 outdoor air concentration level, with an immediate and other delayed effect of 10 days, also with the 12-day lag from the elevation of O3.

Key messages:

- Ambient air pollution is a major risk factor for respiratory health.
- Reducing NO2 emissions could decrease morbidity and direct health care costs of respiratory diseases.

DH Food, nutrition and diet

Do we practice what we preach? Assessing the food environment in Malta's only state hospital

Sarah Cuschieri

S Cuschieri[1], D Cauchi[2]
[1]Anatomy, University of Malta, Msida, Malta
[2]Health Promotion and Disease Prevention Directorate, Ministry for Health, Msida, Malta
Contact: sarah.cuschieri@gmail.com

Introduction:

Food environments are likely to be key contributors to the development of diabetes and obesity. Hospitals should strive to create a model food environment that facilitates and promotes a healthy eating behaviour among visitors, patients and staff. The study objective was to evaluate foods and beverages available for purchase in vending machines at Malta's only state hospital.

Methods:

An observational study gathered data regarding location, type of food and beverage items available in the vending machines found within the public areas within the only state hospital in Malta. All items on sale were categorized into 'healthy' and 'unhealthy' food and beverage according to pre-defined criteria.

Results:

There were 33 vending machines: sixteen offered beverage options, and the remainder contained food items, which displayed exclusively confectionary items. The beverage machines were identically stocked so that bottled water contributed 17%, diet soft drinks 33% and regular soft drinks 50% of overall beverage choices. Fresh vegetables or fruit were not available for sale (except for 1 beverage machine offering fresh squeezed orange juice) with most items on display classified as 'unhealthy'.

Conclusions:

Hospital food environments should complement health professionals' efforts in promoting healthier lifestyles, however, the majority of foods and beverages available for purchase at Malta's only state hospital through vending machines is unhealthy. Urgent action is required to rectify the current situation.

Key messages:

- Vending machines offered 'unhealthy' choices to patients, relatives and staff.
- Hospital food environment should promote healthier food and beverage options.

Situations in which mothers experience difficulty stimulating healthy EBRB in school-aged children

Emilie Ruiter

ELM Ruiter[1], GAJ Fransen[1], GRM Molleman[1], MJHM Hoeijmakers[1], K van der Velden[1], RCME Engels[2]
[1]Academic Collaborative Center AMPHI, Integrated Health Polic, Radboudumc, Nijmegen, Netherlands

[2]Executive Board, Erasmus University, Rotterdam, Netherlands
Contact: emilie.ruiter@radboudumc.nl

Background:

Parental support is an important element in overweight prevention programs for children. The purpose of this study was to examine everyday life situations in which mothers encounter difficulties encouraging healthy energy balance-related behavior in their school-age children.

Methods:

We formed four focus groups containing 6-9 participants each. The participants were mothers of Dutch, Turkish, or Moroccan descent with a child 8-13 years of age. All focus group sessions were recorded, transcribed, and coded. Content was analyzed conventionally using ATLAS.ti 6.

Results:

Twenty-seven difficult everyday life situations were identified in 14 settings. The five most frequently reported situations were a daily struggle regarding eating vegetables, eating breakfast on time before going to school, eating candy and snacks between meals, and spending excessive time watching television and using the computer. A perceived loss of parental control, the inability to establish rules and the failure to consistently enforce those rules were the most commonly cited reasons for why the mothers experience these situations as being difficult.

Conclusions:

We identified five difficult everyday life situations related to healthy energy balance-related behavior. These five difficult situations were used as the input for developing a web-based parenting program designed to prevent children from becoming overweight. We reasoned that if we use these situations and the underlying reasons, many parents would recognize these situations and are willing to learn how to deal with them and complete the e-learning.

Key messages:

- The identified everyday-life-situations in which mothers experience difficulty stimulating healthy EBRBs in their children age 8-13 were used as input for our e-learning program to prevent overweight.
- Mothers who live in low-SES neighborhoods were easily willing to participate in focus groups and discuss EBRB-related topics.

Evaluation of Norovirus contamination in bivalve molluscs harvested from Northern Adriatic Sea, Italy

Stefania Barbieri

S Rubini[1], S Barbieri[2], MN Losio[1], R Taddei[1], B Bertasi[1], E Pavoni[1], E Bolognesi[1], C Berardelli[3], G Govoni[4], E Suffredini[5]
[1]Istituto Zooprofilattico Sperimentale della Lombardia e del, Sede di Brescia, Brescia, Italy
[2]Department of Urgency, Department University of Padova, Padova, Italy
[3]Azienda USL Ferrara, Attività Veterinarie, Ferrara, Italy
[4]International Committee of the Red Cross, ICRC, Geneva, Switzerland
[5]Istituto Superiore di Sanità, Dipartimento di Sicurezza Alimentare, Nutrizione e Sanità Pubblica Veterinaria, Rome, Italy
Contact: stefibarbieri118@gmail.com

Background:

Norovirus (NoV) is the leading cause of acute gastroenteritis in developed countries. Transmission is through direct contact, unsanitary food handling or ingestion of contaminated water or food. Shellfish bioaccumulate NoV and current post-harvest depuration is not effective for its removal.

Materials and

Methods:

A monitoring programme for NoV in bivalve shellfish harvested from Northern Adriatic Sea was initiated in 2016. From January 2016 to March 2019, 418 samples including 257 Manila clams, 73 mussels, 46 striped clams, and 42 oysters, were examined. Mollusc samples were tested for NoV genogroups I (NoV GI) and II (NoV GII) contamination by RealTime RT-PCR according to ISO 15216-2.

Results:

Ninety-three out of 418 tested samples (22.2%) were contaminated by at least one NoV genogroup, the simultaneous presence of the two genogroups was detected in 19/418 of the cases. Positive samples were distributed among the tested species as follow: 29/73 (39.7%) mussels, 51/257 (19.5%) Manila clams, 8/42 (19.0%) oysters, 5/46 (10.9%) striped clam. In 2016 (n = 135), 2017 (n = 122), 2018 (n = 132) and in the first trimester of 2019 (n = 12), prevalence of NoV was 6.7%, 24.6%, 31.8% and 41.4%, respectively. NoV GII was largely predominant being detected, alone or in association with GI, in 98.9% of the contaminated samples. On the other hand, GI prevalence increased from 1.5% (2016) to 12.1% in 2018, maybe reflecting a higher circulation of this genogroup in production environments.

The vast majority of positive samples (91.4%) were detected during the cold season (November to March).

Conclusions:

Overall positive samples have increased over the years (from 6.7% in 2016 to 31.8% in 2018). NoV GII was the most frequently detected genogroup, but NoV GI prevalence significantly raised in 2018. The routine application of quantitative RT-PCR (ISO 15216-1) to determine the viral load in bivalve molluscs would expand knowledge on potential for foodborne transmission.

Key messages:

- Overall positive samples have increased over the years.
- The routine application of quantitative PCR to determine the viral load in bivalve molluscs would expand knowledge on potential for foodborne transmission.

Visual information on labels in commercial baby foods on Bulgarian market

Lalka Rangelova

L Rangelova[1], A Partzova[1]
[1]Food and Nutrition, National Centre of Public Health and Analyses, Sofia, Bulgaria
Contact: l.rangelova@ncpha.government.bg

Background:

Production and sale of commercial baby foods in Bulgaria has grown in the last years. The evidence suggests that inappropriate promotion and advertising of commercial complementary foods can affect unfavourably child nutrition. The World Health Assembly has urged all Member States to ‘‘end inappropriate promotion of foods for infants and young children’’.

Methods:

The survey is part of WHO Regional Office for Europe project: Commercial foods for infants and young children in the WHO European Region. The data was collected in November 2017 in two districts in Sofia, Bulgaria using the mobile questionnaire, developed by WHO. The presence on various types of visual information on the package was recorded for 771 products on the market.

Results:

The results reviled that 94.4% of the labels of baby foods on the market in the capital of Bulgaria - Sofia, use the pictures of ingredients and 52.9% - the cartoon images. The use of images of infants and young children presented in 8.7 % of the products and 6.9% of them marketed as suitable for babies under six months old, in violation of the International Code of Marketing of Breastmilk Substitutes. 0.4 % of baby foods use images of mothers in the labels. The ‘‘other’’ visual information related to various claims including ‘‘quality’’, ‘‘bio’’ (i.e. organic) and various other nutrition and health claims.

Conclusions:

There is inappropriate promotion of commercial complementary foods on Bulgarian market.

Key messages:

- Special measures, including legislative to limit inappropriate practices for the advertising of foods for infants and young children, are needed.
- Raising the parents’ awareness of the criteria for selecting commercial complementary foods is necessary.

A set of pedagogical recommendations for improving the integrated approach to childhood obesity

Emilie Ruiter

ELM Ruiter[1], GRM Molleman[1], GAJ Fransen[1], M Wagenaar[1], K van der Velden[1], RCME Engels[2]
[1]Academic Collaborative Center AMPHI, Integrated Health Polic, Radboudumc, Nijmegen, Netherlands
[2]Executive Board, Erasmus University, Rotterdam, Netherlands
Contact: emilie.ruiter@radboudumc.nl

Background:

Studies increasingly emphasize the importance of the parents' role in interventions designed to prevent overweight in children. The aim of this study was to develop a unified set of recommendations for healthy parenting practices that can be applied by all professionals who work with children age 4-13 years and can contribute to strengthening the integrated approach to childhood overweight.

Methods:

A modified Delphi procedure was used to reach consensus regarding what these pedagogical recommendations should encompass. The 30 panelists were professionals and researchers who work with children in the domains of health care, overweight, parenting, education, nutrition, and/or sports. The procedure consisted of: i) extracting existing pedagogical recommendations from national guidelines and professional protocols, ii) appraising and prioritizing these recommendations in terms of relevance through two rounds of questionnaires, and iii) meeting to discuss and approve the set of recommendations.

Results:

Consensus was reached for one set of eleven pedagogical theme-based recommendations designed to support and instruct parents how to stimulate healthy energy balance-related behaviors in their child. Each recommendation contained information regarding: i) which behaviors are important, ii) why this is important, and iii) how parents can stimulate this behavior by applying parenting skills. The eleven themes were: modeling, positive parenting, breakfast, varied diet, sugar-sweetened beverages, snacks, physical activity, playing sports, quantity of screen time, screen time during meals, and sleep.

Conclusions:

We developed a set of recommendations for healthy parenting that can be used by various professionals working with children age 4-13 and can contribute to creating an integrated approach to childhood overweight. We also developed a web-based app called ''Recommendations for Healthy Parenting'' as a convenient tool for following these recommendations.

Key messages:

- Our set of recommendations for healthy parenting can be used by various professionals who work with school-aged children, thereby helping strengthen the integrated approach to childhood overweight.
- We developed and released a Dutch web app entitled ''11 Recommendations for Healthy Parenting'' to provide a convenient tool for easily communicating these recommendations to parents.

The impact of joining the Eurozone on nutrition habits in Lithuania

Rimantas Stukas

V Dobrovolskij[1]
[1]Department of Public Health, Vilnius University, Vilnius, Lithuania
Contact: rimantas.stukas@mf.vu.lt

Background:

Increases in the cost of food often leads to changes in the quantity and type of foods that are purchased. World Health Organization estimates that today's global food prices rose to the highest level. Numerous research results show that the effect of the conversion of national currencies to the euro on the growth of consumer prices in euro area countries was generally mild and one-off.

The aim - to explore the eating habits in 2019 of the Lithuanian population and compare it with results of an eating habits research which was made before the joining euro zone in 2013.

Methods:

The sample under the survey included 1007 of the Lithuania's population. The interviewing under a questionnaire was carried out in March 2019 using the questionnaire developed for this purpose. Statistical analysis was performed using SPSS program package. The results were compared with nutritional habits of the survey done in 2013.

Results:

The results showed that only one-fifth of the Lithuanian adult population thinks about food choices for health benefits - 22 % (in 2013 - 21 %). Food choice is affected by the taste - 37 % (in 2013 - 28%), to a lesser extent - the food price, which represents 24 % (in 2013 - 37%). 67% of the Lithuanian population (in 2013 - 43%) do not always eat at the same time. 59% (in 2013 - 59%) of the adult population eats three times a day. The majority - 98% (in 2013 - 92.9%) of the respondents had a snack between main meals. It is recommended to eat fresh vegetables every day, but this recommendation is shared by 55% (in 2013 - 40%). The milk and milk products are used each day by 51% (37% in 2013) of the population. The majority - 42% (in 2013 - 82%) of adult Lithuanian population most frequently used vegetable oil.

Conclusions:

More people started to choose food by taste, and a decreased number of those who choose by price. There is increased number of people who eat fresh vegetables every day and decreased number of people who use vegetable oil.

Key messages:

- There are differents in nutrition habits among Lithuania population before and after joining Eurozone.
- The study showed the impact of joining the Eurozone on the diet of the population.

Attitudes, norms and behaviors enhancing unhealthy food choices of high school students in Armenia

Lusine Aslanyan

LA Aslanyan[1], AD Demirchyan[1]
[1]School of Public Health, American University of Armenia, Yerevan, Armenia
Contact: laslanyan@aua.am

Background:

Negative attitudes towards healthy eating behaviors are common among school-aged children. Given the scarcity of studies investigating eating behaviors among adolescents in Armenia, the current study sought to explore eating behaviors among high school students and assess the attitudes, norms and behaviors enhancing unhealthy food choices among them. Theory of Planned Behavior (TPB) was applied as a theoretical framework.

Methods:

A qualitative study with focus group discussions and in-depth interviews was conducted using semi structured interview guides developed based on TPB framework. The study covered high school students aged 15-18 years old, their parents, teachers and school canteen staff, residing in cities and villages of Shirak province, Armenia. Direct content analysis with deductive approach was used for data analysis.

Results:

The most preferred foods by the adolescents were fast foods, sweets, salads and sugar sweetened beverages. Taste was the most powerful attitudinal factor influencing their food choices. Friends and advertisements were the main role models affecting adolescents' eating behaviors. Knowledge on unhealthy food choices and the consequences of unhealthy diet on one's health were adequate among all participants, but unlike rural participants, this factor did not result in healthy eating behavior among urban participants. Lack of time, high cost of food, seasonal changes in food availability, limited food choices in school canteens and low coverage of schools with canteens, especially in the villages, had considerable impact on adolescent's food choices.

Conclusions:

According to the study results, most of the TPB constructs played role in shaping unhealthy eating behaviors among adolescents. Based on the findings, recommendations were made to conduct social advertising of healthy food choices and healthy eating behaviors among adolescents, empower school cafeterias and increase the coverage of schools with cafeterias.

Key messages:

- In Armenia, adolescents' eating behaviors are mainly influenced by taste, availability, and affordability of food choices, eating behavior of peers and advertisements.
- Government needs to increase the coverage of schools with cafeterias and empower school cafeterias, so that they suggest healthy, tasty and affordable food choices.

Food ''from the Outside'' and Correct Nutrition for Outpatients

Aviad Tur-Sinai

A Tur-Sinai[1], *B Bisharat*[1], *S Zelber-Gagi*[2]
[1]Health Systems Management, The Max Stern Yezreel Valley College, Yezreel Valley, Israel
[2]School of Public Health, University of Haifa, Haifa, Israel
Contact: avts2309@netvision.net.il

Background:

It is a common custom to visit patients in hospital. Visitors often bring along outside food products, including some that may not be recommended for the patient. Even so, neither the Ministry of Health nor the hospitals have explicit guidelines in place as to what people can and cannot bring their inpatient friends or kin. The study deals with three main questions: What are the patterns of spending on outside food products for inpatients? What are the types of food products brought for inpatients? How medical professionals view the matter?

Methods:

This quantitative study uses three closed-structured-questionnaire surveys-among visitors, inpatients, and medical staff. Thematic analysis of the findings yields patterns of spending on outside food products for inpatients, the types of food products brought, awareness of the health implications of consuming these products, patterns of consumption among inpatients, and how medical professionals view the matter.

Results:

There are five major findings: (a) Most expenditure on outside food for inpatients occurs in the first few days of hospitalization. (b) Most food brought to inpatients is not defined as healthy. (c) There is a gap between visitors' awareness of the health implications of bringing food to inpatients and their actual conduct. (d) Most patients realize that the food brought to them is bad for their health but tend to eat it anyway. (e) Medical staff disapproves of bringing food to inpatients.

Conclusions:

Information on the extent of bringing food to inpatients, and the types and nature of what is brought, sheds light on the question of food security among inpatients, with emphasis on the motive behind the (in)correct nutrition. Information about the attitudes of patients, visitors, and medical staff toward the need to continue bringing food sheds light on questions of equality and social justice in inpatient care.

Key messages:

- Healthcare services should be more aware of assuring inpatients' right to correct nutrition in the senses of reducing inpatients' exposure to externalities that may impede their convalescence.
- Healthcare services should be more mindful of the advantages of using the egalitarian nutrition system that hospitals operate for all patients.

Evaluation of growth monitoring activity in Yopougon-Est Health District (Abidjan, Côte d'Ivoire)

Francke-Lina Siagbé Gbogbo

F Gbogbo[1], *P Thonneau*[1]
[1]Health Department, Senghor University, Alexandrie, Egypt
Contact: gfrancklina@yahoo.fr

Background:

Malnutrition represents 11% of disease burden in the world and is an underlying cause of 45% of under-5 deaths. Prevention is paramount in the fight strategy. That is why, ''growth monitoring'' which goal is to prevent and to detect malnutrition, has been integrated into health programs. In Côte d'Ivoire, although this activity is carried out in the health centers and despite the existence of Guidelines to improve services, under-5 malnutrition prevalence remains above thresholds. Our purpose was to assess the gap between the National Guidelines for growth monitoring and the practices of health workers.

Methods:

A descriptive cross-sectional study was conducted in all the 6 public health centers of Yopougon-Est District, from August 22 to September 05, 2018. Data were collected using an observation grid developed from the Guidelines and 3 questionnaires. Six growth monitoring sessions were observed; 6 responsibles, 9 health workers assigned to the activity and 133 mothers came to monitor their child were interviewed after informed consent.

Results:

The growth monitoring sessions were held every working day in 4 centers. Half of health workers assigned to the activity had not received training. All centers had baby scale, 5 had horizontal height, but only one had vertical height and person scale. Most health workers (78%) were not aware of Guidelines. The steps of ''interrogation and examination'' component were only 58% completed. The steps for weight measurement were completed at 96% and at 70% for size. The nutritional status of children was evaluated in only one center. In no center, health workers traced growth curve. Nearly half of the mothers surveyed (45%) had not received counseling during their visits.

Conclusions:

The study highlighted shortcomings that do not allow the achievement of growth monitoring objectives. This study cannot be extrapolated however it raises real questions about the quality of the services provided in health centers.

Key messages:

- An evaluation at large scale needs to be conducted and corrective actions to be taken to improve the growth monitoring activity for effective prevention and early detection of malnutrition.
- Growth monitoring will be effective in preventing malnutrition only if it is well conducted by health workers.

Impacts of post-Brexit agricultural policy on fruit and vegetable intake and cardiovascular disease

Paraskevi Seferidi

P Seferidi[1], *AA Laverty*[1], *J Pearson-Stuttard*[1,2], *B Collins*[2], *P Bandosz*[2], *S Capewell*[2], *M O'Flaherty*[2], *C Millett*[1]
[1]Public Health Policy Evaluation Unit, Imperial College London, London, UK
[2]Department of Public Health and Policy, University of Liverpool, Liverpool, UK
Contact: ps2414@ic.ac.uk

Background:

The post-Brexit agricultural regime represents an opportunity to positively influence food systems and improve public health. Health-improving measures could include expanding the UK production of fruits and vegetables (F&V), thus increasing F&V availability. Currently, only 1.4% of total agricultural land in England is allocated to F&V. This study aims to estimate the potential impacts of allocating additional land to F&V production on cardiovascular disease (CVD) and inequalities in England between 2021 and 2030.

Methods:

We used the previously validated IMPACT Food Policy model to translate changes in land allocated to F&V into changes in F&V intake and associated CVD mortality, expressed in number of deaths prevented or postponed (DPPs) by age, sex, and Index of Multiple Deprivation (IMD) quintile. We modelled two scenarios that assumed a linear increase in agricultural land allocated to F&V until it covers a) 10% and b) 20% of all land suitable for production of horticultural crops in England. We assumed that F&V prices would drop to a new equilibrium. We used Monte Carlo simulations to produce uncertainty intervals.

Results:

Our model suggested that by 2030, F&V intake might increase by approximately 4% (95% Uncertainty Interval: 2%-7%) and 8% (4%-13%) respectively, under the first scenario. Under the second scenario, F&V intake could increase by approximately 17% (10%-29%) and 37% (26%-51%) respectively. These increases in F&V intake were associated with 3360 (1760-5920) CVD DPPs under the first scenario and 15700 (9000-24310) under the second scenario in 2021-2030. Our modelled scenarios could also reduce inequalities, with some 16% of DPPs occurring in the least deprived group compared with 22% in the most deprived.

Conclusions:

Policymakers should consider the public health impacts of the post-Brexit agricultural regime in England. Increasing the land allocated to F&V production could substantially reduce the burden of CVD and associated inequalities.

Key messages:

- The post-Brexit agricultural policy can be an opportunity to improve diet and public health in the UK.
- Increasing the agricultural land allocated to fruit and vegetable production in England could reduce the burden of cardiovascular disease and associated inequalities.

Integrated veterinary-medical activity on characterization of shigatoxin producing Escherichia coli

Guido Finazzi

B Bertasi[1], G Finazzi[1], R Colombo[2], C Vignati[2], A Dodaro[2], C Spelta[3], A Romanò[3], F Tel[4], GL Ardissino[4], MV Luini[3]
[1]Food Control, IZSLER, Brescia, Italy
[2]Microbiology Laboratory, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy
[3]Sezione di Lodi, IZSLER, Lodi, Italy
[4]Center of HUS Prevention, Control and Management, Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico, Milan, Italy
Contact: guido.finazzi@izsler.it

Background:

Shiga toxin-producing Escherichia coli (STEC) are an important public health concern as they cause severe conditions (bloody diarrhea and hemolytic uremic syndrome - HUS) and have epidemic potential. Cattle are the main reservoir for the highly virulent STEC O157 strain, and other HUS-associated non-O157 strains. This study aimed to characterize strains from animals and humans and to compare their molecular profiles. Animal isolates were tested for the presence of virulence factors correlated to their pathogenic potential.

Methods:

74 STEC human isolates from 43 clinical cases (sporadic or epidemic) and 270 animal isolates from feces from 62 cattle farms were collected. Epidemiological investigation to collect environmental and suspected food samples was carried out for 22 cases. All isolates were typed with PFGE and their serotype was defined by Real-Time PCR. Animal isolates were also tested for the presence of subAB, saa, tia, cfk, adfO, hlyA, efaI1-lifA5'3', and toxB virulence genes.

Results:

O157 was detected in 44% of human cases, other relevant serogroups O26, O111, O103, O145 in 21, 9, 5 and 5% of cases, respectively. The source of infection was identified in one case (cheese contaminated by a O157 strain). Among animal isolates 2, 0.7, 0.7 and 0.3% were identified as O157, O11, O113, and O145, respectively. PFGE highlighted a high heterogeneicity among animal strains, however no pulsotype common to cattle and clinical isolates was found. adfO, cfk, efaI1-lifA5'3' and toxB were found significantly correlated to eae (intimin).

Conclusions:

Human and cattle strains were not correlated, however STEC diversity in cattle was very high and included some strains potentially pathogenic to humans. For this reason, upholding an integrated surveillance is very important.

Key messages:

- Serotypes relevant to human health were found in cattle in a small but not negligible frequence.
- No direct correlation was found between animal and clinical isolates.

Effect of lifestyle on blood pressure in Portuguese population under antihypertensive drugs

Mario Rui Salvador

MR Salvador[1,4], SC Gonçalves[2,4], GQ Romana[3,4], B Nunes[4], I Kislaya[4], CM Dias[4], AP Rodrigues[4]
[1]Public Health Unit, ACES Dao Lafoes, Viseu, Portugal
[2]Public Health Unit, ACES Medio Tejo, Alcanena, Portugal
[3]Public Health Unit, ACES Lisboa Norte, Lisbon, Portugal
[4]Department of Epidemiology, National Health Institute Doctor Ricardo Jorge, Lisbon, Portugal
Contact: mariorui.salvador@hotmail.com

Background:

Hypertension is one of the main risk factors for disability and death from cardiovascular diseases. Current guidelines include initiatives to control blood pressure values in hypertensive patients that focus on lifestyle changes. The main objective of this study was to estimate the association between lifestyle and blood pressure in patients under antihypertensive drugs.

Methods:

An analysis of the data of Portuguese Health Examination Survey (INSEF) was performed. Individuals who met INSEF inclusion criteria and who referred to be under antihypertensive drugs in the two weeks prior to the questionnaire were studied. Lifestyle variables (alcohol consumption, smoking, additional salt intake, fruit and vegetables consumption, practice of physical activity) were measured by questionnaire, and blood pressure values were obtained by physical examination. Associations between lifestyle factors and blood pressure, stratified by sex and adjusted to sociodemographic variables and to obesity, were estimated through a multiple linear regression model.

Results:

Alcohol consumption ($ß = 6.31$, $p = 0.007$) and smoking ($ß = 4.72$, $p = 0.018$) were associated with systolic blood pressure in men. Additional salt intake, fruit and vegetable consumption, and practice of physical activity were not associated with blood pressure in men. In women, no association was observed for any behavioural variable.

Conclusions:

These conclusions reinforce the need, also in the population under antihypertensive drugs, particularly in the male sex, to focus the fight against high systolic blood pressure in these two modifiable and preventable behaviours: smoking and alcoholic consumption.

Key messages:

- Alcohol consumption and smoking are the behavioral determinants associated with high systolic blood pressure values in men under antihypertensive drugs.
- These conclusions reinforce the need to focus the fight against high systolic blood pressure in the preventable and modifiable behavioural determinants.

Visual food diary - peer support and better diet quality

Taija Puranen

T Puranen[1]*, P Salokekkila*[1]*, N Ahlblad-Makinen*[1]*, A Haggman-Laitila*[1]
[1]Social Services and Health Care Division, City of Helsinki, Helsinki, Finland
Contact: taija.puranen@hel.fi

Background:

Healthy Life -groups are targeted to patients with symptoms of metabolic syndrome, problems with coping or overweight at public health centers in Helsinki. The aim of one-year Healthy Life -group is to give support for self-care and empowerment. The groups are generic, and each participant sets her own goal such as smoking cessation, alcohol or weight management.

Methods:

To create opportunities for positive and empowering diet intervention for working aged population, we have started a pilot study with visual food diary (MealLogger). The nutritionist are coaching the three-month-intervention aiming at improving the diet quality. Participants share photos of their meals with each other and receive peer support.

Results:

During years 2016 - 2018, 445 completed the one-year intervention in Healthy Life -groups. The mean decrease of weight loss was 4 kg (n = 222) and decrease of waist circumference 5 cm (n = 57).

Conclusions:

Since the goal for most participants was weight loss, we decided to offer a modern intervention with MealLogger-application. During year 2019 we will complete six groups (about 100 participants) and we will measure participants food quality, weight, waist circumference, quality of life. The results we report in the autumn.

Key messages:

- To manage overweight epidemic, new prevention strategies are needed in the primary health care.
- Visual food diary enables positive and empowering approach to improve died quality and weight management.

Evaluation, recommendation and implementation of the local hospital catering system

Giulio Barocco

G Barocco[1]*, D Germano*[1]*, V Patussi*[1]*, M Cella*[1]*, L Tiziana*[1]*, A Pernarcic*[1]*, E Occoni*[1]*, A Calabretti*[2]*, P Bogoni*[2]
[1]Azienda Sanitaria Universitaria Integrata Trieste, Trieste, Italy
[2]Trieste University, Trieste, Italy
Contact: giuliobarocco@gmail.com

According to the literature the prevalence of the risk of malnutrition o hospitalized people exceeds 25% of patients, this evidence is also related to low meal satisfaction. To reduce hospital malnutrition it is also important to improve the consumption of meals by implementing organoleptic and nutritional quality (O&NQ).

The Local Health Agency of Trieste (ASUITS) has conducted surveys to find out how to evaluate and improve the procurement qualifications of hospital catering systems (HCS) and how to implement O&NQ. The production processes of meals served in two clinics using Cook Chill (CC) and Cook/Fresh - Hot Hold (CFHH) production process, respectively, were evaluated from 2017 - 2019. The Nutrient Analysis Critical Control Point process was applied for the evaluation of two catering systems. In addition, the antiradicalic power (ARP) of 120 samples of meals by the University of Trieste was analysed. In 2019 an investigation was conducted to compare the satisfaction and ARP content of meals served to patients in two hospital wards (N = 60). The meals to patients of two wards respectively with CC Cold Plating Retherm (PR) and CC Hot PR were served.

Meals produced by the CC production process highlight the average loss of 50% of ARP compared to the CFHH. Meals produced by the CC Cold PR method limit the loss of ARP by 15-40% less compared to the CC Hot PR method. The satisfaction of patients who have consumed meals produced by the CC Cold PR method is double compared to that of patients who have consumed meals produced by the CC Hot PR method. The surveys have produced significant evidence to evaluate hospital meal production processes and to improve O&NQ. The results were used to develop recommendations for the drafting of tender specifications capable of also protecting nutritional variables.

The evaluation of the O&NQ of HCS represents a central determinant of food safety and nutrition security and must be taken into consideration in the procurements procedure.

Key messages:

- Hospital catering contracts must evaluate and guarantee organoleptic and nutritional quality.
- Integrated evaluation of organoleptic and nutritional quality is an integral part of hospital meals.

Integrated guide for public procurement and private contracts of collective catering system and SDGs

Giulio Barocco

G Barocco[1]*, V Patussi*[1]*, M Cella*[1]*, D Germano*[1]*, A Pernarcic*[1]*, T Longo*[1]*, E Occoni*[1]*, D Steinbock*[1]*, A Calabretti*[2]
[1]Azienda Sanitaria Universitaria Integrata Trieste, Trieste, Italy
[2]Trieste University, Trieste, Italy
Contact: giuliobarocco@gmail.com

Surveys (2008-2018) carried out by the Local Health Agency of Trieste (ASUITS) in local collective catering (CC) services of schools, hospitals, nursing homes, and workplaces (25.000 daily meals) have shown some non - adherence to healthier food choices, food standards, procedures and green and social procurement as recommended by the WHO, FAO, UE, Ministry of Health and of Environment.

The purpose of this project is to support local public and private organizations in transforming the national and regional catering services food standards related to health, nutrition, environment and social criteria into food procurement and food contracts specifications. This has been done by compiling the major obstacles to improved standards observed during surveys, and by sharing critical and relevant examples with major public contractors across local, regional and national level.

The guidelines (GL) for public procurement of CC consist of five chapters: the elaboration of specifications; a response module to present the offer of services; selection and award criteria, an evaluation system of offers, and the technical specifications attached. Technical information fixes the constituent elements of the service in order to have similar and directly comparable offers. GL cover both the purchasing of food and the contracting of catering services. In this way public or private institutions are able to prepare tender documents suitable to respond to health, economic needs and Sustainable Development Goals (SDGs).

The development of the GL has increased the awareness and real potential that local organizations have in enhancing the strategic use of purchasers to boost food qualification, jobs, growth and investment. As well as to create a more innovative economy, to be resource and energy efficient, and to be socially-inclusive.

To meet population nutrient intake goals and SDGs it is necessary to increase co-operation and the sharing of the objectives of 'Health in All Policies'.

Key messages:

- Contractors need practical tools to apply sustainable development goals criteria in collective catering.
- The integrated collective catering guide is a key to improving capacity building in institutions.

An Investigation of Family Nutrition and Physical Activity and Affecting Factors in Primary Schools

Ezgi Kozan

E Ekici[1]*, H Ikiişik*[2]*, H Ankarali*[3]*, EH Kozan*[1]*, M Yetim*[1]
[1]Faculty of Health Sciences, Nursing, Uskudar University, Uskudar, Turkey
[2]Faculty of Medicine, Public Health, Medeniyet University, Uskudar, Turkey

[3]Faculty of Medicine, Basic Medical Sciences, Medeniyet University, Uskudar, Turkey
Contact: e.h.kozan@gmail.com

Background:

In this study, it was aimed to determine the family nutrition and physical activity status of primary school students and some affecting factors.

Methods:

In this descriptive and correlation-seeking research, mixed sampling methods were used. The sample size was not calculated, it was aimed to reach all students in three primary schools with different socioeconomic status (high, medium, low) in Uskudar, Istanbul. Data from 727 subjects were collected through an introductory information form and The Family Nutrition and Physical Activity Screening Tool (FNPA).

Results:

In the study, data from 294 (49.7%) girls and 297 (50.3%) boys from three primary schools who studied first grade (n = 321, 54.3%) and 4th grade (n = 270, 45.7%), a total of 591 children were used. The total FNPA score of students in schools with high or middle socioeconomic status was significantly higher than the socioeconomically low school ($P < 0.001$). The mean score of the scale was significantly higher in those who doesn't eat junkfood or snacks ($P = 0.001$), who had regular breakfast ($P = 0.001$) and people with regular meal time ($P = 0.001$). The mean BMI of children in the middle socioeconomic status school was found to be significantly higher than that of students in the low socioeconomic status school ($P = 0.013$). There was also a significant correlation between the mean BMI of mothers and the total FNPA score ($P < 0.001$).

Conclusions:

In the study, as the socioeconomic status of schools increased, FNPA total score increased as well. Although some studies suggest that family income and socioeconomic status are inversely related to childhood obesity, in this research the mean BMI of children in the socioeconomically middle school was significantly higher than the students in the socio-economically low school.

Key messages:

- The evaluation of the nutritional and physical activity status of the family as an element of the obesogenic environment, may be effective on identifying the causes of childhood obesity.
- Studies to determine the nutritional and physical activity of the family in preventing childhood obesity are essential.

Customer satisfaction survey in Friuli Venezia Giulia university canteens

Marco Righini

G Perri[1], M Righini[1], A Tullio[2], M Del Pin[1], M Maifreni[3], M Marino[3], MC Fedele[4], M Parpinel[1]
[1]Department of Medicine, University of Udine, University of Udine, Udine, Italy
[2]Hygiene and Clinical Epidemiology Unit, ''Santa Maria della Misericordia'' University Hospital, Udine, Italy
[3]Department of AgriFood, Environmental and Animal Science, University of Udine, Udine, Italy
[4]Agenzia Regionale per il Diritto agli Studi Superiori (ARDISS), Trieste, Italy
Contact: righini.marco@spes.uniud.it

Background:

Customer satisfaction represents an innovative approach to measure strengths and weaknesses of an organization and is useful for a customer-focused management and culture development. Our survey's aim was to investigate perceived quality and needs of customers in the university canteen sector.

Methods:

Between April and June 2018, an anonymous online questionnaire was distributed by ''agenzia regionale per il diritto agli studi superiori'' (ARDISS) among university students in Friuli Venezia Giulia, Italy. The questions covered 3 thematic areas: attendance of the service, quality of services and opinions on new initiatives. Furthermore, there was an open question to collect students' suggestions or proposals to improve the service. Satisfaction about the service was evaluated through five topics: environments, hygiene, staff, meals, global satisfaction. Collected data were analyzed with descriptive, univariate and multivariate analyses. Statistical analyses were performed using 9.4 SAS software.

Results:

Response rate was 20.5% (1933/9404). Multiple logistic regression analyses showed a difference in meal choice (entire vs reduced) between institutional canteen and partner cafeterias users ($p < 0.0001$) and that male ($p < 0.0001$) and foreign students (p 0.0003) prefer entire meal instead of reduced. Percentage of students who prefer entire meal is reduced ($p < 0.0001$) if price range increases. Univariate and multivariate analyses showed that high quality perception is associated with lower price range and no suggestions about food and environments ($p < 0.0001$); multivariate analyses also showed an association between high quality perception and high canteen attendance ($p < 0.05$).

Conclusions:

The survey showed an association between meal choice and students' profile and between perceived quality and customer's features. These data and further analyses may help to select areas where an intervention could improve service quality and, therefore, customer satisfaction.

Key messages:

- Customer satisfaction is an important tool to measure and improve university canteen service quality.
- These results helped us to identify services' strengths and weaknesses according to students' opinions; this could be useful to select improvement areas.

Main sources of information on nutrition of various socio-economic groups

Žymantas Žandaras

Ž Žandaras[1], R Stukas[1]
[1]Faculty of Medicine, Institute of Health Sciences, Vilnius University, Vilnius, Lithuania
Contact: zymantas.zandaras@gmail.com

Backgroud:

For effective non-communicable disease prevention and health promotion programs, it is very important to know from where the targeted audience gets all the information on nutrition (NI). The shortage of this information lead to the aim of this study - to determine the main sources of NI of various socio-economic groups.

Methods:

Cross-sectional study was conducted in 2019. 1007 residents of Lithuania aged 18-75 were surveyed by anonymous questionnaire. Survey was carried out by using multi-stage stratified random sampling. Chi square test was used for the data analysis.

Results:

More than half respondents (58.6% (95% CI: 55.5; 61.6)) indicated that one of their main sources of NI is internet, 47.2% (95% CI: 44.1; 50.3) of respondents trusts television and radio. Only one third of residents (36% (95% CI: 33.1; 39.1)) indicated physicians and pharmacists as the main source of NI and only 20.6% (95% CI: 18.2; 23.2) of them received NI from specialized nutrition and health magazines. Younger people were more likely to choose internet as the main source of NI (65,7%, 58%, 54,1% accordingly ($p = 0.004$)). Internet as the main source of NI was significantly related to residence, education, income and marital status. The number of respondents who identified television as the main source of IN was significantly higher among the rural population (53.2%) and small-town population (52.9%) than among the population of big cities (39.4%) ($p < 0.0001$). Choosing television as one of main source of NI was significantly related to age, education, income and marital status. 24.3% of women and 16.4% of man indicated that the main source is specialized nutrition and health magazines ($p = 0.002$).

Conclusions:
Best place for spreading NI is internet and television. When trying to target young people the best place is internet and for targeting senior citizens NI is better to carry out by television and radio.

Key messages:

- Most population gets information about nutrition from internet and television.
- Most young people gets information about nutrition from internet and most older people gets information from television and radio.

Determination of Orthorexia Nervosa Symptoms and Eating Attitudes in Medicine Students

Ali Ozer

Ö Erol[1], A Özer[1]
[1]Faculty of Medicine, Public Health Department, Inonu University, Malatya, Turkey
Contact: aliozer91@hotmail.com

Background:
Orthorexia Nervosa (ON) is defined as obsession with healthy eating. It is known that the purity is more important than amount or energies of consumed food in people with ON.With this condition,ON results in restrictions on food intake in individuals.According to the literature, health professionals are in the risk group of ON. The aim of this study is to examine orthorexia nervosa symptoms and eating attitudes of medicine students.

Methods:
This cross-sectional study was conducted on 298 students who educated Inonu University Faculty of Medicine in 2017.Data collection tools were General Information Form,ORTO-15,EAT-40.SPSS 22.0 and Pearson Exact,Fisher's,Chi-Square tests were used for statistical analysis.

Results:
%76.2 of students had orthorexia tendency, %11.1 of students had eating disorders. 24 aged students were found to less orthorexic than others and obese students tend to have less orthorexic than others. It was found that when reached true information about nutrition, individuals who changed their eating behavior always had more orthorexic than rarely. It was found that when reached true information about nutrition, individuals who changed their eating behavior always had more eating disorders rate (EDR) than others. It was found individuals who received information from book-scientific publications had EDR than others and individuals who received information from dietitians had higher EDR than those who did not ($p < 0.05$). In addition, %12.3 of the individuals who tend to orthorexia and %7 of the individuals who tend to without orthorexia were found to have eating disorders.However,the difference between groups was not statistically significant ($p > 0.05$).

Conclusions:
According to our results, it is emphasized that question which "Is ON an eating disorder?". In addition, we believe that our study will contribute to the literature because ON, eating attitudes and information sources of nutrition are examined together on medicine students.

Key messages:

- When individuals have access to nutritional information, behavior change states affect the tendency to orthorexia nervosa and eating disorders.
- Nutritional and psychotherapeutic interventions for behavioral regulation of individuals are thought to reduce the tendency of orthorexia nervosa and eating disorders.

Early feeding profiles based on breastfeeding, infant formula and introduction of solid foods

Hélène Amazouz

H Amazouz[1,2], N Bougas[1,2], B de Lauzon-Guillain[3,4,5], I Momas[1,2,6], F Rancière[1,2]
[1]Université Paris Descartes, Faculté de Pharmacie de Paris, Paris, France
[2]UMR1153-CRESS, team HERA, Inserm, Paris, France
[3]U1125-CRESS, team EAROH, INRA, Paris, France
[4]UMR1153-CRESS, team EAROH, Inserm, Paris, France
[5]Université Paris Descartes, Paris, France
[6]Cellule Cohorte, Mairie de Paris, Direction de l'Action Sociale de l'Enfance et de la Santé, Paris, France
Contact: heleneamazouz@gmail.com

Background:
As early feeding practices may be related with allergy at older age, we aimed to investigate infant-feeding profiles in the first year of life and their determinants in the PARIS (Pollution and Asthma Risk: an Infant Study) cohort.

Methods:
This study included 3446 infants. Feeding data was collected using standardized questionnaires at 1, 3, 6, 9 and 12 months. At each time, we considered 6 variables such as (i) breastfeeding (no, mixed, exclusive), consumption of formula (no, yes): (ii) regular formula, (iii) hypoallergenic, (iv) with pre-/probiotics, or (v) extensively hydrolyzed/soya, as well as (vi) solid foods introduction (no, yes: 0, 1, ≥ 2 allergenic foods). Children with similar feeding profiles over the first year of life were grouped together using multidimensional longitudinal cluster analysis. Socio-demographic and health determinants of these profiles were examined using multinomial logistic regression models.

Results:
Five distinct profiles were identified. Profile 1 (45%) included children mainly fed with regular formula. Children from Profile 2 (27%) were exclusively breastfed during the first 3 months. Children from the other three profiles were moderately breastfed and differed regarding the type of formula consumed: pre-/probiotics for Profile 3 (17%), hypoallergenic for Profile 4 (7%), or extensively hydrolyzed/soya for Profile 5 (4%). Profiles did not seem to differ regarding timing of solid foods introduction, except Profile 5 starting later. Compared to Profile 1, children from Profiles 2 to 5 were more likely to have parental history of allergy and higher family socioeconomic status (SES). Profile 5 appeared to be influenced by early health outcomes such as eczema or food reactions.

Conclusions:
We identified different early feeding profiles. Parental history of allergy, SES and early health outcomes seem to be important determinants of these profiles. Associations of these profiles with the development of allergic disease will be studied.

Key messages:

- These results are important to better understand early-life feeding practices and their contributors.
- Their possible role in helping to prevent allergic diseases in later life will be further studied.

Background characteristics of meat consumption exceeding the Finnish Dietary Guidelines in 2000-2017

Elviira Lehto

E Lehto[1], N Kaartinen[2], K Sääksjärvi[2], S Männistö[2], P Jallinoja[1]
[1]Health Sciences, Tampere University, Helsinki, Finland
[2]Public Health, National Institute of Health and Welfare, Helsinki, Finland
Contact: elviira.lehto@tuni.fi

Background:
Abundant consumption of animal-based foods such as red and processed meat pose a threat to sustainability and public health. This study clarifies how the share of the population group with high red and processed meat consumption has changed in the past two decades.

Methods:
We used data of four Finnish cross-sectional surveys: Health 2000 (n = 5976), DILGOM 2007 (n = 4874), FINRISK 2012 (n = 4812), and FinHealth 2017 (n = 6010) concerning 25-74 year-old subjects (in year 2000 30-74 year-olds). Habitual food consumption over the past 12 months was assessed with a validated130-item food frequency questionnaire (FFQ) and daily meat consumption was computed. Questionnaires inquired on general background factors. The risk in belonging

to the meat consumption quintiles exceeding the Finnish Dietary Guidelines (500 g /week) was examined with logistic regression analyses.

Results:

In 2000, consuming more meat than recommended was more probable among men and those with lower or middle educational level. In 2007 and 2012, in addition to gender and education, having middle or higher income level and belonging to the age group of 35-44 years was associated with higher meat consumption. In 2017, meat consumption was higher among men, those with lower educational level and among 45-64 years old, but no income level differences were observed.

Conclusions:

Actions aiming to reduce meat consumption should be targeted to those consuming the largest amount of meat: men, middle-aged, and those having lower educational level.

Key messages:

- The group consuming more meat than recommended has remained stable in the 21th century to include more often men, middle-aged, and people having lower education but income has become non-significant.
- Identification of population groups with high meat consumption helps to better design and target the interventions and to change the consumption patterns in a healthier and more sustainable direction.

Drinking water quality: results from the data analysis in Lombardy region

Samuele Rivolta

S Rivolta[1,2], *G Diurno*[2], *E Ammoni*[2], *S Castaldi*[1,3], *M Gramegna*[2]
[1]Department of Biomedical Sciences for Health, University of Milan, Milan, Italy
[2]Direzione Generale Welfare, Regione Lombardia, Milan, Italy
[3]Direzione Sanitaria, Fondazione IRCCS Ca' Granda OMP Milano, Milan, Italy
Contact: samu.rivolta@gmail.com

Background:

Ensuring access to safe and quality drinking water is an essential aspect of public health, as well as a fundamental human right as an extension of the right to life affirmed by the Universal Declaration of Human Rights. Previously in Lombardy, the reporting of water sampling control activities was prepared only by the local health authorities (LHAs). Recently, however, the activation of a data centralization information system allows the monitoring of the whole regional territory and the elaboration of a periodic report.

Methods:

The data relating to the analytical checks on drinking water in the Lombardy Region were extracted from the regional database for 2014, 2015 and 2016 and grouped by 'Chemical', 'Microbiological' and 'Indicators' parameters.

The analysis focused on the number and analytical compliance of all the samples performed. All the results considered both the overall regional data and each LHA.

Results:

From a quantitative point of view, the activity of entering the sampling data seems to progressively improve, remaining rather heterogeneous among the various LHAs.

From a qualitative point of view drinking water in Lombardy is to be considered good overall: both the chemical and microbiological non-compliant samples in Lombardy are lower than 10% for the years 2014 and 2015 and lower than 5% in 2016 thus indicating an apparently improving trend.

Conclusions:

For a better evaluation of the numerical appropriateness of the controls carried out, an update of the registry system of the supply areas and a more uniform LHA programming is necessary.

For a better assessment of the quality of water destined for human consumption oriented to the conformity of parameters, it is necessary to adopt an analytical judgment system on individual parameters instead of on the entire sample. A further improvement will be the inclusion in the database of the data of the aqueduct managers included in the Water Safety Plans (WSPs).

Key messages:

- Water quality assessment and its control activity reporting is an essential aspect in public health prevention.
- It is essential to strive for continuous improvement in the data collection method to better monitor potential risks and to evaluate the best future safe water supply strategies.

Breastfeeding knowledge and attitudes of young people

Marija Jevtic

D Dimovski[1], *J Gajic*[1], *B Vukajlovic*[1], *M Jevtic*[1,3], *A Komlenic*[2]
[1]Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia
[2]Faculty of Philosophy, University of Novi Sad, Novi Sad, Serbia
[3]Institute of Public Health of Vojvodina, Novi Sad, Serbia
Contact: marija.jevtic@uns.ac.rs

Background:

One of the World Health Organizations (WHO) global nutrition goals by 2025 is to increase the rate of exclusive breastfeeding of infants under six months to at least 50%, which can be achieved only through educating future parents on the importance of breastfeeding. The goal of this research was to establish the current effects of the public health campaigns in raising awareness on breastfeeding by analyzing the opinions of young people towards maternal milk.

Methods:

The study was conducted as a prospective study for six months in 2018. and in 2019. 281 people participated (158 female, 123 male) of whom 127 psychology students.The participants had no children, and were aged between 18 and 26.. The survey consisted of socio-demographic questions and the Iowa Infant Feeding Attitude Scale (IIFAS) with 17 questions. Data processing included methods of descriptive and inferential statistics using the MedCalc program. Values of $p < 0{,}05$ were considered statistically significant.

Results:

More than one out of two female and almost two out of five male participants recognized milk as a diet optimal for their infant (53% female, 38% male). Over twice as many participants considered maternal milk to be extremely positive in comparison to baby formulas as positive. Only 12% of respondents acknowledged that infants had beneficial effects from breastfeeding throughout their lives.

Since only 12.8% of infants in Serbia are exclusively breastfed (according to the available data), the public health authorities need to take more drastic measures in order to complete the WHO set goal by 2025.

Key messages:

- Current public health campaigns aren't showing sufficient effects.
- Both sexes need to be included in education process about the importance of breastfeeding.

Risk assessment of Portuguese population to multiple mycotoxins: the human biomonitoring approach

Carla Martins

C Martins[1,2,3], *A Vidal*[6], *S De Saeger*[6], *C Nunes*[2,4], *D Torres*[5,7], *A Goios*[5,7], *C Lopes*[5,8], *R Assunção*[1,3], *P Alvito*[1,3], *M De Boevre*[6]

[8]Department of Public Health and Forensic Sciences, and Medical Education, Faculty of Medicine, University of Porto, Porto, Portugal

Contact: carla.martins@insa.min-saude.pt

Mycotoxins constitute a relevant group of food contaminants with several associated health outcomes such as estrogenic, immunotoxic, nephrotoxic and teratogenic effects. Although scarce data are available in Portugal, human biomonitoring studies have been globally developed to assess the exposure to mycotoxins at individual level.

The present study concerned the analysis of mycotoxins in 24h urine and first-morning urine paired samples from 94 participants enrolled within the scope of the National Food, Nutrition, and Physical Activity Survey of the Portuguese General Population (2015-2016). Following a salt-assisted matrix extraction, urine samples were analyzed by liquid chromatography-mass spectrometry for the simultaneous determination of 37 urinary mycotoxins' biomarkers and data obtained used to estimate the probable daily intake as well as the risk characterization applying the Hazard Quotient approach.

Results revealed the exposure of Portuguese population to zearalenone, deoxynivalenol, ochratoxin A, alternariol, citrinin and fumonisin B1 through the quantification in 24h urine and first-morning urine paired samples. Risk characterization data revealed a potential concern to some reported mycotoxins since the reference intake values were exceeded by some of the considered participants. Alternariol was identified for the first time in urine samples from a European country; however, risk characterization was not performed due to lack of reference intake value.

The present study contributed with reliable and evidence-based results, and confirmed that mycotoxins represent a burden and are part of the human exposome of the Portuguese population. Further studies are needed to shed a light on the determinants of exposure in order to contribute for the promotion of public health measures to reduce the mycotoxins' exposure in Portugal.

Key messages:

- Portuguese population is exposed to mycotoxins, chemical food contaminants that may be harmful (carcinogenic, immunotoxic, mutagenic, teratogenic, hepatotoxic) for human health.
- Human biomonitoring studies provide realistic data on internal exposure at individual level, allowing a more accurate knowledge of the determinants of exposure to these contaminants.

Burden of disease attributable to exposure to aflatoxins in Portugal using Human biomonitoring data

Carla Martins

C Martins[1,2,3], A Vidal[6], M De Boevre[6], S De Saeger[6], C Nunes[2,4], D Torres[5,7], A Goios[5,7], C Lopes[5,8], P Alvito[1,3], R Assunção[1,3]

[8]Department of Public Health and Forensic Sciences, and Medical Education, Faculty of Medicine, University of Porto, Porto, Portugal
Contact: carla.martins@insa.min-saude.pt

Human biomonitoring (HBM) is recognized as an important tool to assess the Human exposure to chemicals, contributing to describe trends and patterns of exposure over time and to identify population groups that could be under risk. Natural chemicals as mycotoxins, fungi metabolites that produce toxic effects in humans, are important compounds that could be found in foods usually consumed worldwide in a daily basis. Mycotoxins as aflatoxins (AFTs) are genotoxic, carcinogenic and immunosuppressive compounds. Hepatocellular carcinoma (HCC) is one of their main health toxic effects and is the third leading cause of cancer deaths worldwide. In Portugal, scarce data are available regarding exposure to AFTs and none previous study used HBM data to characterize comprehensively the burden associated to this exposure.

In the scope of the National Food, Nutrition, and Physical Activity Survey of the Portuguese General Population (2015-2016), 24h-urine samples from 94 participants were analyzed by liquid chromatography-mass spectrometry (LC-MS/MS) for the simultaneous determination of AFTs (B1, B2, G1, G2, M1). A model was developed to estimate the health impact of the exposure of Portuguese population to aflatoxins, estimating the number of cases of HCC and DALYs attributed to AFTs exposure.

AFTs were detected in 12.8% (AFB1), 16.0% (AFB2) and 19.1% (AFM1) of the 24h-urine samples. The estimated number of extra cases of HCC attributed to this exposure ranged from 17 to 65 cases/year; the associated DALYs for the Portuguese population ranged from 284 to 1802 years.

The present study generated, for the first time and within a HBM study, reliable data regarding the exposure of the Portuguese population to AFTs. These data were crucial to characterize the health impact associated to AFTs exposure and to support risk managers to establish preventive policy measures that contribute to ensure the public health protection.

Key messages:

- Portuguese population is exposed to aflatoxins, chemical food contaminants that may be harmful (carcinogenic, immunotoxic, mutagenic, teratogenic, hepatotoxic) to humans.
- Human biomonitoring studies provide realistic data on internal exposure at individual level, contributing to a more accurate estimation of the burden derived from this exposure.

Dietary polyphenol intake and socioeconomic status in adult russian/siberian population

Irina Berezovikova

I Berezovikova[1], D Denisova[1]
[1]Research Institute of Internal and Preventive Medicine, Novosibirsk, Russia
Contact: ira_ber@mail.ru

Background:

Polyphenol consumption from polyphenol-rich foods (tea, coffee, fruits, vegetables at all) is inverse associated with the risk of cardiovascular- and other noncommunicable chronic diseases and varies in different regions due to dietary habits, as well as by socioeconomic factors.

Methods:

Participants: the Siberian urban population (Novosibirsk, HAPIEE study, 9324 (4,249 men and 5,075 women) aged 45-69 years. Dietary data collected using a 141-item food frequency questionnaire. Data on the polyphenols were taken from the Phenol-Explorer database (version 3.6). Total polyphenols (TPH) were considered as a sum of all individual classes: flavonoids, phenolic acids, stilbenes, lignans and other polyphenols and their food sources. Socioeconomic status included gender, educational, occupational and marital status.

Results:

The main sources of TPH were tea, coffee, fruits, vegetables and rye bread. Average total polyphenol consumption was 1273 (647) in men and 1203 (626) mg/day in women ($P < 0,05$). By occupational status, consumption of TPH in unemployed men was lower - 1139 (442) mg/day vs 1282 (648) in employed, working pensioners and unemployed pensioners ($P < 0,05$). The consumption of TPH in women: in unemployed pensioners: 1176 (613) vs 1220 mg/day in employed and working pensioners. The main polyphenols intake in all occupational groups were flavonoids (66,1-67,6 % total polyphenols), followed by phenolic acids (21,4-22,3%). TPH consumption in groups with less education than primary in men was lowest: 1052 (476) mg/day vs 1273 (646) ($P < 0,05$ vs men with higher education). In men and women with high education was highest consumption of lignans. The maximum consumption of polyphenol compounds was established in groups of married men and women:1279 (646) and 1231 (632) mg/day, respectively, P < 0,05 vs single individuals.

Conclusions:

The consumption of polyphenol compounds in the Siberian urban population is determined by the socioeconomic status.

Key messages:

- The main individual classes of polyphenols consumed in all educational and marital status groups were the same as in the employment group: flavonoids, followed by phenolic acids.
- Recommendations for consumption of polyphenol compounds for the prevention of chronic non-communicable diseases in Siberia should consider the socioeconomic status of the population.

Estimating the burden of disease of exposure to chemical contaminants in food in Denmark

Lea Jakobsen

LS Jakobsen[1], ST Thomsen[1], SM Pires[1]
[1]Division of Diet, Disease Prevention and Toxicology, Technical University of Denmark, Kgs Lymgby, Denmark
Contact: leaja@food.dtu.dk

Background:

Recent global estimates have shown that dietary exposure to chemical contaminants cause over 56,000 deaths and 9 million healthy life years lost each year. However, the contribution of causative agents varies greatly between world regions and countries due to local food consumption and contamination. To prioritize public health interventions to reduce disease burden, national-level risk ranking evidence is needed. The overall aims of this project are to estimate the burden of disease (BoD) of selected chemical hazards in foods consumed in Denmark, and to identify the relative contribution of foods.

Methods:

We identified chemicals on the basis of their presumed public health impact. The final list of chemicals was defined in agreement with the Danish Veterinary and Food Administration, and included: methylmercury, inorganic arsenic, cadmium, acrylamide, dioxin/dioxin-like PCBs and lead. We estimated BoD in terms of disability adjusted life years (DALY) in a model combining exposure assessment with dose response models to derive probabilities of health effects, taking an incidence-based approach. Data were collected from the Danish National Survey of Diet and Physical Activity, food monitoring, literature, and national statistics.

Results:

We estimated that methylmercury, inorganic arsenic, cadmium and acrylamide lead to a BoD of 514 DALY (95% uncertainty interval: 185, 990) in 2016 (preliminary results). Estimates for lead and dioxin/dioxin-like PCBs are pending. Methylmercury exposure from fish was the greatest contributor to overall burden (478 DALY), and acrylamide from potato products the second (30 DALY). The health outcomes leading to highest burden were intellectual disability and cancer.

Conclusions:

Our estimates will assist public health managers identifying the chemical contaminants in foods with the highest impact on public health in Denmark. Future research should focus on estimating the effect of mitigation strategies on the disease burden.

Key messages:

- We provide national quantitative evidence of the health impact of chemical exposures from foods.
- Information on the relative contribution of foods and population groups affected may focus mitigation.

DI Health assessments: impact, technology

Evaluation of the effects of health impact assessment (hia) practice in monteregie

Kareen Nour

K Nour[1]
[1]Public Heath Department Montérégie, Longueuil, Canada
Contact: kareen.nour.agence16@ssss.gouv.qc.ca

This study explores the effects of the collaborative model of health impact assessment (HIA), as deployed in Monteregie (Quebec), on the development, adoption and implementation of municipal projects that include health considerations.

Nine HIA processes were studied in nine territories and 35 individuals were interviewed. Data collection was based on the six steps of contribution analysis, and included document analysis, semi-structured interviews, and on-site observations.

The study results showed that the HIAs had varying results. First, the actors involved acquired new knowledge. However, the HIAs had little impact in terms of increasing the municipal actors' awareness of health issues. Rather, it helped them acquire arguments for raising awareness among and convincing their municipal council members of the merits of certain actions and their potential positive impacts on citizens' health. In fact, the HIAs were generally undertaken by municipal actors already aware of the importance of promoting citizen health. Second, in a few of the HIAs, some recommendations were integrated into planning documents, but usually the HIA report constituted an additional planning document and was not merged with the original planning documents. Lastly, following the HIAs, most of the municipal actors continued to include health considerations in their subsequent planning of public policies and projects.

Prerequisites for effective HIA include the presence of municipal actors who are aware of the importance of their role in their local population's health, municipal policies that include health considerations, and the municipality's active participation in the HIA process.

This study sheds light on the complexity of the factors that ensure HIA impact on municipal decision making and decisions.

Key messages:

- HIA have a significant impact to change municipality practice.
- The HIA process is crucial in order to have an impact on municipal projects that include health considerations.

Nursing community 2.0: a method to promote online collaborative learning

Roberta Arnone

R Arnone[1], MI Cascio[1], I Parenti[1], A Catino[1], ML Zoda[1], VC Botta[1]
[1]CEFPAS, Caltanissetta, Italy
Contact: arnone@cefpas.it

This article describes a project seeking to establish an online community of practice involving nurses in Sicily, known as Nursing Community 2.0. The Community has initially involved 585 Sicilian nurses who took part in the residential activities. They had been selected thorough a questionnaire addressed to measure the initial technological competencies. All students - registered on open source LMS (Moodle) - attended DL courses promoted by CEFPAS (Centre for training and Research in Public Health located in Sicily). To promote collaborative Learning, Learning Community provided 4 areas: Forum, to confront and to debate about professional interests moderated by a renowned nurse; Camera Cafè, a virtual ''agora'' to change opinion without a moderator; The corner of the joke; a Tweetboard; Project work Area, where the Topic has been developed to be presented during the last examination. Indeed, the project was designed to provide nurses with a space for building collaborative relationships, exchanging professional knowledge and practices, developing competencies, shaping organizational policy and reporting Adverse Drug Reactions. The quality of solutions will depend on the professional and on the nature of the competencies to be developed. The impact of a training initiative addressed to an adult public through the technological tool, depends both on the interest for the topic and on the ability of the user to manage own training, to acquire familiarity with network services and technologies and, when it occurs, to be able to autonomously cope with training using technologies useful to get information and knowledge to be used to solve a specific professional problem in time. Qualitative and quantitative analysis of online interactions have been carried out. Results indicate that, thanks to the deployment of suitable technology and expert tutor support, Nursing Community 2.0 has successfully established itself as an environment for generating and exchanging knowledge.

Key messages:

- Collaborative learning depends on the interest for the topic and on the ability of the user to manage learning through technological tools.
- Nursing Community gives results when learning environment generates debates and interactions.

Identification of a strategy for disinvestment in the Italian National Health Service (NHS)

Chiara Cadeddu

C Cadeddu[1]*, E Di Brino*[1]*, F Campisi*[1]*, A Meloni*[1]*, S Romeo*[1]*,*
M Montemagno[1]*, A Cicchetti*[2]*, M Marchetti*[1]
[1]National Centre for Health Technology Assessment, Istituto Superiore di Sanità, Rome, Italy
[2]ALTEMS, Università Cattolica del Sacro Cuore, Rome, Italy
Contact: chiara.cadeddu@iss.it

The disinvestment of ineffective or inappropriate technologies or interventions with an inadequate value for money ratio is a growing priority in order to contribute to the objectives of maintaining high quality and appropriate care and allocation of resources that guarantee the sustainability of the National Health System (NHS).The possibility of reallocating resources from obsolete and no longer appropriate technologies, allows for recovered resources to be allocated to technological innovation and therefore to the overall sustainability of the system.In order to define criteria concerning disinvestment techniques of health technologies and strategies of obsolete technologies to be applied within the Italian reference framework, we started an ongoing research project.

A systematic review of the scientific literature of the last 10 years was carried out on 5 different databases with the purpose of analyzing the international disinvestment experiences of health technologies using the Health Technology Assessment (HTA) method and focusing on orthopedic prosthesis procedure and cardiac stenting procedure.By means of National Dataset of the Italian National Institute of Health, real consumption and estimated consumption have been identified,using the Italian NHS perspective.

The preliminary systematic review retrieved a total of 548 records. Nine results were finally included. In the development of disinvestment strategies, particular attention must be paid to the identification of an integrated model between the different levels of the NHS (national,regional,local). In Italy there are no prior example of broad and complex disinvestment experiences using HTA methodologies. Effective disinvestment strategies require a systematic approach coordinated by a national body and implemented at regional level,to be extended to cascade to the organization and provision of services and services by health companies,and required to actively involve health professionals and citizens.

Key messages:

- Identifying effective strategies for disinvestment of health technologies is crucial, considering continuous health innovation and improvement and development opportunities.
- HTA methodologies, such as reassessment, could support disinvestment processes and represent a systematic and objective approach to be implemented and used at different levels of Italian NHS.

Knowledge and Attitude towards the Gradual Reduction of Salt in Bread – an Online Survey

Alexandra Costa

A Costa[1]*, L Costa*[1]*, J Santos*[2]*, P Braz*[2]*, M Santos*[3]*, R Brazão*[3]*, I Lopes*[4]*,*
A Guerreiro[5]*, J Alves*[6]*, T Caldas de Almeida*[1]
[1]DPS, National Institute of Health Doutor Ricardo Jorge, Lisbon, Portugal
[2]DEP, National Institute of Health Doutor Ricardo Jorge, Lisbon, Portugal
[3]DAN, National Institute of Health Doutor Ricardo Jorge, Lisbon, Portugal
[4]Directorate General of Education, Lisbon, Portugal
[5]Regional Health Administration of the Algarve, Lisbon, Portugal
[6]National School of Public Health (ENSP-NOVA), Lisbon, Portugal
Contact: alexandra.costa@insa.min-saude.pt

Background:

Bread is one of the main sources of salt intake in Portugal. Based on this evidence, a protocol signed between national Health Sector and the Associations of Industrial Bakeries, in 2017, established gradually decrease salt in bread until 2021. This measure also targets schools' available bread, this should not exceed 1g salt, to end of 2018. A pilot Health Impact Assessment (HIA) aims to assess the potential impact on salt reduction in bread on the eating habits of children (6-18 years) and their families.

Methods:

A questionnaire is being performed to assess the effect of this measure. The first version was designed by a panel of 11 experts (content validity), following the plain text principles. A external specialist revised it for facial validity. A pilot was tested. Thereafter, a REDCap online survey of ''Knowledge and Attitude towards the Gradual Reduction of Salt in Bread'' questionnaire was finalized. The target group is the parents or guardians of children and young persons, of School Clusters in the south of Portugal.

Results:

Final online survey totalizes 33 items, divided into four blocks: 1.Knowledge and General literacy data, 2.Domestic Consumption, 3.Scholar consumption and 4.Sociodemographic. An adult responsible for the child/young person should answer the survey. Access is possible through a REDCap link, using computers available in the School Cluster, or other manner suitable for the purpose.

Conclusions:

This survey will contribute to the identification of modifiable behaviors related with salt intake. Such evidence may eventually provide the opportunity for new strategies in this area.

Key messages:

- Health Impact Assessment as a procedure to assess the effects of measures and policies on human health.
- Questionnaires are a rapid tool to access perceptions, attitudes and knowledge.

Cost-effectiveness analysis of low-dose computed tomography screening for lung cancer in Hungary

Zoltan Voko

Z Voko[1,2]*, A Molnar*[2]*, V Valay*[1]*, M Moizs*[3]*, A Kerpel-Fronius*[4]*,*
G Bajzik[3]*, I Horvath*[4]*, B Nagy*[1,2]
[1]Department of Health Policy & Health Economics, Eötvös Loránd University, Budapest, Hungary
[2]Syreon Research Institute, Budapest, Hungary
[3]Mor Kaposi Hospital of Somogy County, Kaposvar, Hungary
[4]Koranyi National Institute for Tuberculosis and Pulmonology, Budapest, Hungary

Contact: voko@tatk.elte.hu

Background:

Hungary has the highest incidence of lung cancer in the world (GLOBOCAN, 2018). Since lung cancer is rarely treatable in its advanced stage, one possible way to reduce mortality is early diagnosis and subsequent treatment. The possibility and necessity of introducing low-dose computed tomography (LDCT) lung cancer screening as a public health programme is a current and relevant health policy issue.

Methods:

A Markov cohort model was built to assess the cost-effectiveness of such a risk group screening programme in Hungary. The model was populated with transition probabilities and resource utilization data derived from the HUNCHEST Hungarian lung cancer screening trial. The model results are presented in incremental cost-effectiveness ratio.

Results:

A closed cohort of 10,000 smokers with the average starting age of 59 years was followed over life-time horizon and screened for lung cancer annually until the age of 74. Compared to the current scenario of no organized lung cancer screening in Hungary, the model resulted in an additional 0.1614 life-year gained per individual and an additional 0.2924 disease-free life-year gained per individual with annual screening frequency. The incremental cost-effectiveness ratio was EUR 608 indicating that assessed intervention is cost-effective in the analyzed setting. Sensitivity analyses confirmed the robustness of the model results.

Conclusions:

Results suggest that introducing low-dose computed tomography screening for lung cancer is a cost-effective intervention in Hungary. Considering the exceptionally high incidence and mortality of lung cancer in Hungary, the population could benefit from such a risk group screening programme.

Key messages:

- Low-dose computed tomography screening for lung cancer is cost-effectiveness in the Hungarian setting.
- Policy makers are encouraged to consider the introduction of a risk group screening programme.

Digital technology interventions to reduce loneliness in adults: a systematic review

Syed Ghulam Sarwar Shah

S G Sarwar Shah[1], *David Nogueras*[2], *Hugo van Woerden*[3], *Vasiliki Kiparoglou*[1]

[1]NIHR Oxford Biomedical Research Centre, Oxford University Hospitals NHS Foundation Trust, John Radcliffe Hospital, Oxford, UK

[2]DNM Consulting, 7, 2 London Bridge Walk, London, UK

[3]Centre for Health and Science, University of the Highlands and Islands, Old Perth Road, Inverness, UK

Contact: Sarwar.Shah@ouh.nhs.uk

Background:

Loneliness is an emerging public health issue and its burden is increasing in developed countries. Loneliness is associated with social, emotional, physical and mental health issues. Tackling loneliness is important to reduce its adverse impacts on individuals with loneliness and their families. Various digital technology-based interventions are used to tackle loneliness. Assessing the effectiveness of these interventions is important from the health, social care and public health perspectives.

Aim:

To undertake a systematic review of published primary research on digital technology interventions to reduce loneliness in adults.

Methods:

Databases searched: PubMed, Medline, CINAHL, EMBASE and Web of Science. Inclusion criteria: empirical research articles involving the application of digital technology interventions for tackling loneliness; participants aged ≥ 18 years and publication in the English Language from 1 January 2010 to 14 January 2019. Two researchers systematically screened articles and data were extracted from shortlisted articles applying a population, intervention(s), comparator(s) and outcome(s) (PICO) framework.

Results:

We selected 14 studies mostly from developed countries such as the US (n = 5) and Sweden (n = 3). We found a wide variation in the sample sizes (range 5-591 participants), participants' age (range 32-90, average 66.4-82.5 years) and the follow-up measurement period (6 weeks-12 months) in the selected studies. Digital technology interventions tested were Internet-based social activities and networking through video or phone calls (using Skype (n = 6) and Facebook (n = 2)), communicating via emails (n = 2). Most of the studies used the UCLA loneliness scale (n = 9) and reported reductions in loneliness in follow-up measurements compared to baseline measurements.

Conclusions:

Digital interventions are associated with reduced loneliness in adults; however, further studies such as clinical trials involving larger sample sizes are needed.

Key messages:

- Loneliness is associated with social, emotional, physical and mental health problems and the burden of loneliness is increasing, especially in developed countries.
- Digital technology interventions help in reducing loneliness in adults but further research including clinical trials involving large sample sizes and longer follow-up periods are required.

The psychometric properties of a short version of the General Self-Efficacy Scale: A Rasch analysis

Anne Mari Steigen

AMS Steigen[1], *HSF Finbråten*[1], *ALK Kleppang*[2]

[1]Health and Nursing Sciences, Inland Norway University of Applied Sciences, Elverum, Norway

[2]Public Health and Sport Sciences, Inland Norway University of Applied Sciences, Elverum, Norway

Contact: anne.steigen@inn.no

Background:

Self-efficacy is important in adolescence and is found to affect adolescents' physical activity, risk-taking behaviour and health decisions. Self-efficacy describes a person's belief in own coping abilities. Having good measures of self-efficacy may contribute to more valid knowledge about the potential role of self-efficacy as a health promoting factor in adolescents lives. Several scales measuring self-efficacy exists. One of these is the General Self-Efficacy Scale comprising 10-items. However, there exists several short versions of the scale. In a large cross-sectional study among adolescents in secondary schools in Norway, five of the items from the General Self-Efficacy Scale are used. The aim of this study is to examine the psychometric properties of this short version of the General Self-Efficacy Scale applying Rasch measurement theory.

Methods:

This study is based on cross-sectional data from the Youth Data Survey. The data collection was carried out in lower and upper secondary schools in Norway during 2018. In total, 6646 adolescents responded to a web-based questionnaire. The data were analysed using the partial credit parameterization of the unidimensional Rasch model.

Results:

Preliminary results indicated that the short version had acceptable reliability (person separation index: 0.78). However, the targeting could have been better (mean person location: 1.441). All items had ordered thresholds. One under-discriminating item and three over-discriminating items were identified. Three items displayed differential item functioning with regard to gender and one item displayed differential item functioning for school level.

Conclusions:

Based on our preliminary findings this short version of the General Self-Efficacy Scale has the potential to measure self-efficacy among adolescents, but there are room for improvements. The scale has some shortcomings related to targeting and differential item functioning that needs to be further explored.

Key messages:

- The short version of the General Self-Efficacy Scale has the potential to measure self-efficacy in adolescents.
- The scale has some shortcomings that needs to be further judged.

Unexpected effect of smoking/drinking cessation among computed tomography lung screening consumers

Cheng-Che Chen

C-C Chen[1,2], W-C Wu[3], D-C Chan[4,5]
[1]Division of Psychiatry, National Taiwan University Hospital Chu-Tung Branch, Hsinchu, Taiwan
[2]Center of Medical Education and Research, National Taiwan University Hospital Chu-Tung Branch, Hsinchu, Taiwan
[3]Department of Health Promotion and Health Education, National Taiwan Normal University, Taipei, Taiwan
[4]Superintendent Office, National Taiwan University Hospital Chu-Tung Branch, Hsinchu, Taiwan
[5]Department of Internal Medicine, National Taiwan University Hospital, Taipei, Taiwan
Contact: hugocc@gmail.com

Background:

Low-dose computed tomography (LDCT) screening is an innovated tool for lung cancer prevention. The findings of LDCT trials indicated that the screening could increase the motivation of smoking cessation for high-risk groups. However, none studies have investigated the associations between commercial LDCT lung screening and unhealthy behaviours among those customers.

Methods:

We established a prospective observational study at a community hospital in Taiwan. In total, 1326 customers of the commercial LDCT lung screening without lung cancer history were recruited. At the day of screening, interviewers collected their baseline demographic information and smoking/drinking habits. Only 605 participants completed two follow-up surveys at the 3rd and 12th month. Screening findings were defined as 'normal' if there were no nodules or only definitely benign nodules and as 'abnormal' if any lung nodule or ground-glass opacity were found. We applied the generalised linear mixed model to estimate the effects of time and screening findings on daily smoking and weekly drinking.

Results:

The rates of daily smoking (weekly drinking) decreased from 13.1% (15.5%), to 10.9% (12.9%) in the 3rd month, and 7.9% (12.4%) in the 12th month. The associations between abnormal screening findings and smoking (-0.25, 95% CI: -0.77,0.28) or drinking (0.13, 95% CI: -0.29, 0.56) cessation are not significant. The time effect on smoking cessation was persistent (-0.23 and -0.62 at the two periods, 95% CI: -0.39, -0.07 and -0.85. -.038), and the effect on stopping drinking was relatively small (-0.23 and -0.28 at the two periods, 95% CI: -0.43, -0.04 and -0.52, -0.04).

Conclusions Commercial LDCT screening would decrease the rates of smoking more than drinking among these consumers, and the abnormal finding was not further associated with cessations. It implies that commercial screenings may be beneficial for decreasing unhealthy behaviours as a teachable occasion.

Key messages:

- Commercial LDCT lung screening program may have benefits for decreasing smoking and even drinking behaviours among the non-specific high-risk population.
- It might be a good moment for health providers and practitioners to conduct cancer-related health education during commercial screening programs.

The Villeneuve renovation program Health Impact Assessment

Lucie Anzivino

L Anzivino[1]
[1]Observatoire Régional de la Santé, Lyon, France
Contact: lucie.anzivino@ors-auvergne-rhone-alpes.org

We conducted a health impact assessment (HIA) on a french urban renovation program in a disadvantaged neighborhood: the Villeneuve, symbol of the architecture of the great ensembles of the 1970s. The ambitions of this new program are opening to the city, simplification of traffic, requalification of the housing stock, creation of living spaces renovation of public facilities enhancement green spaces ... so many challenges to be met for the attractiveness of the territory and its inscription in the heart of the Metropole. The HIA was conducted collaboratively with the services of the city of Grenoble, Echirolles, and the Metropole.

The information used to inform the assessment included profiling the community of the Villeneuve, a comprehensive literature review focussing and semi-structured interviews. Many components of the project were evaluated: access to good quality of green and public spaces; urban design; mobility; access to shops and services and social cohesion.

The HIA shows that the urban renovation program is likely to have a mix of negative and positive impacts on health, mental health, wellbeing and social cohesion. In particular on the living environment, the attractiveness, the perception of the neighborhood, on physical security and sense of security, opening of neighborhoods, mix functionality, opportunity for leisure and sports practices. In addition the program provides an opportunity to specifically target reducing health inequalities in the area.

The HIA working group has co-built 47 recommendations. These recommendations were than hierarchized according to four criteria: political portability - cost- technical feasibility - temporality.

This HIA is a structured approach that allowed the renovation program to be observed with a holistic vision of health around the determinants of health and encouraged partnerships and anticipate health issues as early as possible in the decision-making process of urban programs.

Key messages:

- The HIA is a structured approach that allows urban projects to be observed with a holistic vision of health around the determinants of health.
- The HIA encourage partnerships and anticipate health issues as early as possible in the decision-making process of urban programs.

Breast Cancer Screening (BCS) by Mammography Tomosynthesis

Maria Filomena Correia

M Correia[1,2], F Aleixo[3,4], A Lagoa[5], D Ferrinho[1], R Pereira[1], L Vale[1], C Cardoso[1], M Faria[3]
[1]Regional Screening Department, ARS Algarve, Faro, Portugal
[2]Public Health, ARS Algarve, Faro, Portugal
[3]Radiology Department, Algarve Onchologic Association, Faro, Portugal
[4]Radiology Department, CHUA, Faro, Portugal
[5]Gynecology Department, CHUA, Faro, Portugal
Contact: filomenahcorreia@gmail.com

Issue:

Breast cancer is the 2nd cause of death for women in Portugal and 6000 new cases are detected annually. The prognosis is better for women whose cancers are detected earlier.

Description:

Algarve BCS begin in 2005 using a digital mammography with 2 incidences/breast with double reading and consensus by a 3rd radiologist. Each 2 years women age 50 to 69, are invited to a Mobile Unit to do the mammography, a partnership with Algarve Oncologic Association. In 2017, direct digital mammography with Tomosynthesis(DDMT)was implemented. This technique increase cancer detection, reduction of false positives, false negatives and radiation dose. Diagnostic accuracy is better and also improves accessibility to the most vulnerable population groups to this technology.

Results:

BCS covers 100% of the region and the mobile unit is user friendly for women with mobility impairment. Adhesion rate is > 62%. Is the 1st screening using Tomosynthesis in Portugal.Preliminary results show that the confirmation rate increased (10 %), the detection rate per 1.000 women also increased and the positive predictive value >95%.

Costs associated with the program decrease and less number of women called for false positives is observed. The number of positive mammograms increased, due to diagnostic acuity, with better visualization of the breast, namely in the patterns of greater mammary density; which leads to an improvement in further assessment rates.

Lessons:

The technique increases the adhesion rate, with the same human resources. The decrease of the false positives improves the number of women send to further assessment and Senology Center. Earlier diagnoses, less aggressive treatments, and a higher survival rate are also expected.

Messages- Using this technology is expected that cancer diagnosis will be earlier, more reliable and wiht higher survival rate for this disease. The possibility of a population based screening with DDMT is an opportunity to reduce inequalities in the region.

Key messages:

- Mammography Tomosynthesis is expected that cancer diagnosis will be earlier, more reliable and wiht higher survival rate for this disease.
- The possibility of a population based screening with Mammography Tomosynthesis is an opportunity to reduce inequalities in the region.

Evaluation of the Health impact assessment (HIA) deployment process in a French region

Francoise Jabot

F Jabot[1,2]*, J Romagon*[1]*, G Dardier*[1]
[1]Department of Human and Social Sciences, EHESP, Rennes, France
[2]UMR 6051, Arènes Research Unit, Rennes, France
Contact: francoise.jabot@ehesp.fr

Background:

Health impact assessment is a method aimed at identifying the potential health impacts of policies and projects before their implementation and suggesting proposals in order to mitigate negative impacts and enhance positive ones. HIA is growing in France mainly at the local level. The Pays de la Loire Regional Health Agency (PDL-HRA) took an early interest in HIA and supported three experiments proposed by the town councils. An assessment was performed to judge its added value, identify success factors and draw lessons for the development of the practice.

Methods:

An evaluation framework was built based on standards and literature. Using a qualitative multiple case study design, a cross-sectional analysis of the HIAs was carried out in order to compare the implementation process in their respective contexts, the governance arrangements and the changes introduced as a result of the HIA. Evaluation draws upon HIA reports, workshops, field observation and 40 interviews that were analysed with NVivo.

Results:

While the conduct of HIAs is generally in line with standards of practice, the analysis of the relevance of HIA and impact characterization remain insufficiently documented. Implementation and success factors depend on the political context, the culture of institutions, actors and the purpose of HIA. Recommendations have been taken into account and changes are emerging. The stakeholders indicate their interest in HIA insofar as it is a meeting point between the concerns of institutions regarding health equity and democracy and it provides tools for action.

Conclusions:

Although the approach is unanimously valued, it faces time, resource and competition with other activities. The continuation of the approach depends on the HRA policy specifying the aims, resources, fields of application and positioning with regard to the partners.These findings are consistent with other French work and literature data. French experience coulfd benefit from that of other countries.

Key messages:

- Skills of professionals have to be reinforced in order to make appropriate and quality HIAs.
- Evaluation is useful for understanding the development of an emerging practice and for supporting a decision-making in terms of scaling up, integration, role assigned to the health sector.

Different designs of additional payments for new technologies: The approach of Germany and the USA

Cornelia Henschke

C Henschke[1,2]
[1]Department of Health Care Management, Technische Universität Berlin, Berlin, Germany
[2]Margolis Center for Health Policy, Duke University, Durham, USA
Contact: cornelia.henschke.1@tu-berlin.de

Background:

Health systems have to balance access to technologies, ensure safety and quality, and manage expenditures. As payment rates of prospective payments do not reflect higher costs of technologies, additional payments were implemented. The study aims at comparing the principles of Medicare's New Technology Add-on Payments (NTAP) and payments for new diagnostic and treatments methods in Germany (NUB), and analyzing the development of additional payments over time.

Methods:

A literature review was conducted using public domains of regulatory bodies and databases to compare payment approaches according to a) technologies' eligibility criteria, b) their designs, c) implemented reforms, and d) conducted evaluations. Published data of responsible institutions was used to descriptively analyze the number of technologies authorized for additional payments in hospitals (2005-2018).

Results:

Major differences between payment approaches were identified. The design differs regarding application and payment processes. While in Germany, a single hospital wishing to use the technology has to request for authorization, in the US the manufacturer starts the application process. The NUB-approach allows for payment negotiations per technology between insurers and a certain hospital, the amount of NTAP-payments is calculated per case using a calculation scheme based on real hospital costs. Hospitals, thus, may only be partially compensated for the higher costs of technologies. Only limited evidence exists on the effects of these payments.

Conclusions:

Both approaches improve access to technologies compared to prospective payments. However, different designs indicate different incentive structures, which can affect patient's access. Implicitly, both designs seem to limit excessive technology utilization. Further studies are necessary to evaluate the impact of additional payments on real utilization rates, outcomes and expenditures in order to optimize the design of those payments.

Key messages:

- Additional payments can improve access to technologies compared to prospective payments, but seem to limit excessive technology utilization at the same time.
- Different designs come along with different incentive structures to use technologies. Further empirical research is needed to analyze effects on real utilization rates, outcomes and expenditures.

Quantitative Health Impact Assessment Methodology for Societal Initiatives: A Scoping Review

Laurens Reumers

LM Reumers[1], MPM Bekker[2,1], MWJ Jansen[1,3], HBM Hilderink[4], D Ruwaard[1]
[1]Health Services Research, Maastricht University, Maastricht, Netherlands
[2]Department of Social Sciences, Wageningen University & Research, Wageningen, Netherlands
[3]Dutch Community Health Services Zuid-Limburg, Heerlen, Netherlands
[4]Public Health Foresight, Netherlands Environmental Assessment Agency, Bilthoven, Netherlands
Contact: l.reumers@maastrichtuniversity.nl

Background:

Promoting health rather than treating disease is gaining popularity and promotion initiatives are increasingly situated in the societal domain. In this scoping review, the literature on quantitative health impact assessment (HIA) practice and methodology is explored in order to provide an overview of methods that have been used or proposed for estimating societal initiatives' health outcomes.

Methods:

Systematic searches were done in PubMed and Web of Science in order to identify relevant literature. A set of selection criteria ensured that studies held useful quantitative HIA methodology and a societal approach. Reference lists of all selected studies were then examined for other studies. After literature selection, quantifiable features of interest were recorded and general observations on the composition of the current literature were made.

Results:

The literature selection process yielded 54 included studies, most of which focus on lifestyle-related determinants. Of different health outcome measurements, deaths (averted) was most frequently used, followed by life years and quality- and disability-adjusted life years. Equity is frequently mentioned, but not often estimated. Most studies made estimates based on simulation models, notably with Monte Carlo, Markov and system dynamics models (simulation period mean 46 years; median 50 years). Inputs for the models such as relative risks, transition probabilities and price elasticities were taken from census and register data, survey data, evidence from previous (scientific) studies and outcomes from stakeholder sessions.

Conclusions:

HIA holds a wide range of practices with some overlap. Different methods' strengths and weaknesses partly depend on the phenomenon of interest. Some policy types have standard approaches, but there is no one universal optimal method and therefore having a grasp of multiple methods is useful. Furthermore, estimating health effect distributions could make an important addition to HIA.

Key messages:

- Quantitative HIA can be conducted using various methodological bases and most studies use some form of simulation modelling. Different simulation methods are distinct, but do show some overlap.
- Quantitative HIA topics often relate to individual behaviour (micro-level proximal determinants). There is room for HIA method development for determinants with indirect connections to the individual.

Hospital contextual factors affecting the use of health technologies: a systematic review

Adriano Grossi

A Grossi[1], I Hoxhaj[1], I Gabutti[2], E Carini[1], AM Pezzullo[1], P Cacciatore[1], ML Specchia[1,3], A Cicchetti[2], S Boccia[1,3], C de Waure[4]
[1]Sezione di Igiene, Istituto di Sanità Pubblica, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Alta Scuola di Economia e Management dei Sistemi Sanitari, Università Cattolica del Sacro Cuore, Rome, Italy
[3]Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy
[4]Department of Experimental Medicine, University of Perugia, Perugia, Italy
Contact: adriano.grossi@yahoo.it

Background:

Healthcare systems are facing great challenges due to increased share of aging population, growing health needs and economic restraints. To keep a high quality of assistance it is important to invest in health technologies (HTs) that have the potential of improving health outcomes. Even though a lot of guidance does exist on how HTs should be introduced, used and dismissed, there is a surprising gap in literature concerning the awareness of hospitals in the actual utilization of HTs, namely utilization in daily practice after formal adoption.

Methods:

We performed a systematic literature review of qualitative and quantitative studies aimed at investigating hospital contextual factors that influence the actual utilization of HTs at hospital level. PubMed, Scopus, Web of Science, Econlit and Ovid were searched to retrieve studies published in English from 1st January 2010 to 31st May 2018.

Results:

A total of 33 studies were included mostly addressing information and communication technologies (ICTs). Findings suggest that contextual factors that impact on actual utilization of HTs at hospital level are ascribable to four main families: financial factors, leadership styles, human resource management and hospital infrastructure. It emerges also that involving professionals at all levels and planning people's work and competencies are major determinants of HTs actual utilization.

Conclusions:

The evidence suggests that several contextual factors play a major role in HTs actual utilization at hospital level even though data are mostly referred to ICTs being the other HTs unexplored. Indeed, findings from this study suggest that numerous items should be evaluated when considering to use a new HTs at hospital level. Nevertheless, evidence regarding actual utilization of medical and surgical HTs is still lacking and future research is needed.

Key messages:

- Financial factors, leadership styles, human resource management, hospital infrastructure are relevant determinants of actual utilization of new HTs at hospital level.
- The evidence on contextual factors that influence actual utilization of HTs is mostly referred to ICTs and further research is indeed deserved.

DK Health at work, Social security

Usefulness of the results of a surveillance program for uncompensated work-related diseases in France

Maëlle Robert

M Robert[1], A Fouquet[1], S Rivière[1], P Delezire[1], J Homère[1], L Garras[1], J Chatelot[1]
[1]Environment and Occupational Health Division, Santé Publique France, Saint-Maurice, France
Contact: Maelle.ROBERT@santepubliquefrance.fr

Background:

French employees receive compensations for diseases officially recognized as professionnal disease. Reimbursment data are thus used to produce statistics. Such data do not integrate uncompensated work-related diseases (UUWRD) defined as likely to be of occupational origin but not recognized as well. In 2003, the National Public Health Agency implemented a surveillance program on UWRD. This program is a complement to the compensation system for occupational diseases.

This communication presents results UWRD program can provide.

Methods:

Twice a year, a network of volunteer occupational physicians (OP) reports ill health and associated work exposures of employees. Employee sociodemographics are notified. In 2018, half of French regions are integrated in the program.

Prevalence rates are calculated for UWRD. Chi-squared tests are used to compare prevalence rates between groups. Multivariate logistic regressions are conducted to evaluate:1- risks to report UWRD between groups, 2- prevalence rates trends. Underreporting rates of UWRD are approximated using an indicator capturing differences between figures produced by UWRD program and the compensation system.

Results:

Over the 2009-2014 period, women working in mass food retail were observed at higher risk to present musuculoskeletical disorders than women of other sectors (ORa = 2.0). Same results were noted for men (ORa = 1.3). In mass food retail, decreases in musculoskeletal disorder prevalence rates were reported. Estimated average annual change rates were of 7.0 % for women and 11.0% for men. In 2011, UWRD data highlighted that between half and three-quarter of work-related musculoskeletal disorders were unreported by the compensation system.

Conclusions:

UWRD data are used to identify vulnerable groups, analyse temporal trends and evaluate underreporting of professionnal disease.

Key messages:

- URWD program is a complement to the compensation system and let to better monitor health status of communities.
- Such informations are of interest to guide prevention policies.

Emotional demands at work and risk of depressive disorder: A nationwide Danish cohort study

Ida EH Madsen

IEH Madsen[1], AC Svane-Petersen[1], E Framke[1], JK Sørensen[1], R Rugulies[1,2]
[1]National Research Centre for the Working Environment, Copenhagen, Denmark
[2]Section of Epidemiology, Department of Public Health, University of Copenhagen, Copenhagen, Denmark
Contact: ihm@nrcwe.dk

Background:

Studies suggest that high emotional demands at work are associated with increased risk of depression. However, most previous studies have measured emotional demands using self-report and estimates may be inflated due to reporting bias. Furthermore, no study has yet accounted for the potential selection of individuals with increased risk of depressive disorder into occupations with high emotional demands.

Methods:

We analyzed data from two separate nationwide register-based Danish cohorts, The Danish Work Life Course Cohort (n = 955,712; person-years = 6.99 mill.), and the JEMPAD study (n = 1,680,214; person-years = 21.73 mill.). We measured emotional demands annually by job exposure matrices, and depressive disorder using registers on psychiatric hospital treatment. Emotional demands were categorized as quartiles. To account for selection into jobs with high emotional demands, we adjusted for numerous confounders, including health services use before workforce entry, parental socioeconomic position, and psychiatric and somatic diagnoses. The present abstract reports preliminary results based on a subset of the study population used as a development sample (n = 16,163, person-years = 168,889). Final results will be available for the conference.

Results:

Preliminary findings showed a tendency towards an increased risk of depressive disorder for employees in occupations with the highest level of emotional demands (hazard ratio: 1.20 (95% CI: 0.85-1.69). The association was similar with and without adjustment for confounders and was not explained by selection into occupations with high emotional demands.

Conclusions:

If confirmed in analyses of the full study population, our results suggest that high emotional demands at work may be associated with increased risk of depressive disorder, and that this association is explained by neither reporting bias nor a selection of individuals vulnerable to depression into occupations with high emotional demands.

Key messages:

- Emotional demands may be associated with an increased risk of depressive disorder.
- Further research is needed to explore the potential for workplace prevention of high emotional demands.

Cardiovascular and respiratory diseases and neoplasms in seafarers and farmers in Denmark

Kimmo Herttua

K Herttua[1]
[1]University of Southern Denmark, Esbjerg, Denmark
Contact: kherttua@sdu.dk

Background:

Seafaring is a very specific occupational environment and seafarers are exposed to many health risks. On the other hand, regular medical examinations are obligatory to get permission for working onboard. We sought to estimate relative risk of hospital contacts due to neoplasms, cardiovascular and respiratory diseases among seafarers compared to farmers, as a relevant land-based trade.

Methods:

The participants were all seafarers and all farmers aged 18-65 year at the baseline and residing in Denmark. Two cohorts with baselines in 2002 (n = 56,216) and 2012 (n = 42,000) were linked to records from Danish health registers. We calculated the hazard ratios of hospital contacts using Cox regression models separately for men and women.

Results:

In all disease categories, the risk for hospital contact was greater among male seafarers compared with male farmers. The adjusted hazard ratios (HR) for the 2012 cohort for neoplasms, cardiovascular and respiratory diseases were 1.36 (95% CI: 1.17 to 1.58), 1.16 (1.01 to 1.32), and 1.51 (1.28 to 1.78), respectively. Among female seafarers, the HR for the 2012 cohort for respiratory diseases was 1.58 (1.18 to 2.10), but for cardiovascular diseases 0.73 (0.54 to 0.99). Differences for neoplasms were marginal among women. The incident rates and differences decreased in cardiovascular diseases and increased in neoplasms and respiratory diseases, particularly in men.

Conclusions:These data suggest that seafaring is associated, compared with farmers, with a substantially increased risk of neoplasms, cardiovascular and respiratory diseases among men.

Key messages:

- Seafaring is associated, compared with farmers, with a substantially increased risk of neoplasms, cardiovascular and respiratory diseases among men.
- The incidence rates were highest for CVD in men and for neoplasms in women.

Social validity for work ability assessments and official decisions – clients' experiences

Elin Karlsson

E Karlsson[1], J Sandqvist[2], C Ståhl[1]
[1]Department of Medical and Health Sciences (IMH), Linköping University, Linköping, Sweden

[2]Department of Social and Welfare Studies (ISV), Linköping University, Norrköping, Sweden
Contact: elin.a.karlsson@liu.se

Background:

Professionals need to be able to express what is at stake during the decision-making process and the discrepancy between formal rules and practical rationality need to be bridgeable and transparent for outsiders. Investigations of social validity for work ability assessments are rare. However, the concept can provide valuable information upon the acceptability and comprehensibility of procedures and how professionals can increase clients' participation.

The purpose of this study was to investigate social validity for work ability evaluations within the sickness insurance system and the official decisions they lead to.

Methods:

This was a longitudinal qualitative study using telephone interviews and files from the Swedish Social Insurance Agency. Clients (n = 30) were interviewed after their participation in a work ability evaluation as well as after receiving an official decision upon eligibility for sickness benefits. Data was analyzed using a deductive content analysis.

Results:

Preliminary findings show that clients' comprehensibility of the different tests and their composition were depending on whether the specific tests were perceived as clearly related to the clients' difficulties and what information they had received. In order to receive a fair description of the client's work ability, clients state that the work ability evaluation needs to be individually adapted and that the standardized structure is not relevant for all. What is acceptable and fair to one client could be unacceptable to another, depending on what arguments and information case-managers and evaluation professionals provided.

Conclusions:

Authorities need to express and motivate the reasons for a diverse range of steps during clients sick-leave process, not only regarding official decisions. Social validity for work ability evaluations is depending on the provided information and the applicability to the clients' situation.

Key messages:

- Social validity is depending on the provided information and the applicability to the clients' situation.
- Authorities need to communicate clearly with clients through the whole sick-leave process.

Longitudinal analysis of work-family conflict and self-rated health among working parents in Germany

Lea-Sophie Borgmann

LS Borgmann[1], P Rattay[1], T Lampert[1]
[1]Department of Epidemiology and Health Monitoring, Robert Koch-Institute, Berlin, Germany
Contact: borgmannl@rki.de

In the wake of a rising labor market participation of women and changing and family arrangements, parents are increasingly faced with the challenge of reconciling work and family life, which can lead to work-family conflicts (WFC). The present study examined the longitudinal effect of WFC on self-rated health among working parents in Germany.

The data was drawn from wave 6 (2013) and wave 8 (2015) of the pairfam family and relationship panel. It included working persons living together with at least one child (662 mothers and 529 fathers). Pairfam is a random sample of about 12,000 persons drawn from German habitants in private households. Data was collected via computer-assisted personal interviews with yearly follow-ups. The drop-out rate of the panel from wave 1 to wave 8 is 62%. Self-rated health was measured as a single item with five response options. Using logistic regressions, we estimated the longitudinal effects of the effect of WFC in wave 8 on self-rated health. Moderating effects of education and household income were considered. The analyses were adjusted for self-rated health in wave 6.

The odds ratio for poor self-rated health for mothers who developed WFC in wave 8 compared to mothers who did not report a conflict in both waves was 2.6 (95% CI: 1.47-2.41). For fathers with newly emerged WFC in wave 8, the odds ratio was 2.1 (95% CI: 1.08-3.80). Interaction of WFC with education and household income showed a weak non-significant effect on the self-rated health of mothers and fathers. The health of parents who reported a conflict in wave 6 but not in wave 8 was on a similar level as the health of parents with no conflict in both waves.

The results point out that WFC can lead to a decline of self-rated health. Further investigations should be carried out to determine groups who are particularly affected by health-related outcomes of WFC. It also remains to be discussed how self-rated health can be improved e.g. through reconciliation policies.

Key messages:

- Work-family conflict leads to a poorer self-rated health of working parents in Germany.
- The health of working parents with lower education and income is affected more severely by work-family conflict compared to parents with higher education and income.

Work-related diseases in temporary workers in France between 2009 and 2014

Stéphanie Rivière

S Rivière[1], V Tassy[2], I Bonmarin[3], J Chatelot[3]
[1]Department of Region, Public Health France, Saint Maurice, France
[2]Work Medical Inspection, Regional Directorates for Businesses, Competition Policy, Consumer Affairs, Labour and Employment (DIRECCTE), Nantes, France
[3]Department of Occupational Health (DST), Public Health France, Saint Maurice, France
Contact: stephanie.riviere@santepubliquefrance.fr

Background:

The percentage of temporary workers in the workforce has increased in many European countries. The working environments of temporary workers are often characterized by job insecurity and exposure to hazardous working conditions. Studies have investigated the health status of this population but few of them have specifically investigated work-related diseases. The aim of this study is to compare the risk of uncompensated work-related diseases (UWRD) in temporary workers with permanent contract workers in France between 2009 and 2014.

Methods:

UWRD and suspected associated exposure factors were notified by occupational physicians involved in French UWRD surveillance programme. Sociodemographic and professional characteristics were recorded for all salaried workers consulted by occupational physicians. We analysed musculoskeletal (MSD) disorders (elbow, hand/wrist, shoulder, back) and mental health disorders (MHD) according the type of consultation (periodic check-up, hiring...) using logistic regression. The distributions of notified exposure factors for MSD and MHD were compared between temporary and permanent workers.

Results:

Of the 433 148 salaried workers consulted as part of the surveillance programme, 5.3% and 80.2% had temporary and permanent contracts, respectively. Temporary workers were as likely to have work-related shoulder, elbow and hand/wrist MSD as permanent workers. The former had a lower risk of MHD irrespective of the type of consultation ([OR] = 0.4, 95 % CI 0.3-0.5) and a lower risk of back MSD during on-demand/return-to-work consultations ([OR] = 0.2, 95% CI 0.1-0.5) and during periodic check-ups ([OR] = 0.3, 95% CI 0.2-0.7).

Conclusions:

Temporary workers were not at a higher risk of UWRD (MSD and MHD) than permanent workers. This suggests that the generally poor health status found in temporary workers in previous studies may be linked more to their general health status and perceived job insecurity than to poorer working conditions.

Key messages:

- In our study, the risk of work related musculoskeletal disorders and mental health disorders in temporary workers was no greater than that in permanent workers.
- Poor general health known in temporary workers, may be linked more to their general health status, job insecurity and decreasing career trajectory than to poorer working conditions.

High mortality in manual occupations and the role of alcohol in 2001-2015 in Finland

Hanna Rinne

H Rinne[1], *M Laaksonen*[2], *V Notkola*[3]
[1]Rehabilitation Foundation, Finland, Helsinki, Finland
[2]Finnish Centre for Pensions, Helsinki, Finland
[3]University of Eastern Finland, Kuopio, Finland
Contact: hanna.rinne@kuntoutussaatio.fi

Background:

High mortality is concentrated in low socioeconomic positions which may largely be explained by excessive use of alcohol. The aim was to identify specific manual occupations with high mortality and to examine whether there are differences in the role of alcohol in explaining the excess mortality among manual occupations with high all-cause mortality.

Methods:

A register-based study of employees aged 30-64, followed for mortality 2001-2015. Age standardized mortality ratios (SMR) were calculated to compare the mortality rates of manual occupations. The contribution of alcohol related mortality to excess mortality was obtained by comparing the excess mortality in all deaths and deaths not related to alcohol.

Results:

Men had 31 and women 11 manual occupations with SMR statistically significantly over 120 compared to all employees. Mortality rates were highest among building construction labourers (SMR 180, 95% CI 163-199) among men and building caretakers (SMR 155, 95% CI 135-179) among women. With few exceptions, high mortality was a combination of high alcohol-related and high non-alcohol-related mortality. Among men, the contribution of alcohol-related mortality to the excess all-cause mortality compared to all employees was over 10% in half of the high mortality occupations. Among women excluding the alcohol-related deaths had a minor effect on all-cause mortality.

Conclusions:

Diminishing the alcohol-related mortality would level excess mortality of high mortality manual occupations but not eliminate it. Targeting the improvement of working conditions and occupational health care to certain occupations would diminish the mortality differences between occupations and social classes.

Key messages:

- To prevent the high mortality of manual occupations, improvements should be targeted to several different aspects of working conditions.
- Occupational health care of manual occupations with high mortality should be improved and provide with early interventions towards risky alcohol behaviour.

Effects of sickness absence on disability pension risk: Finnish register study of two native groups

Kaarina Reini

K Reini[1], *J Klein*[1], *J Saarela*[1]
[1]Demography Unit, Åbo Akademi University Vaasa, Vaasa, Finland
Contact: kaarina.reini@abo.fi

Background:

Sickness absence and disability pension have a close connection and both describe the health of working-aged populations. The aim of this paper was to study if Swedish and Finnish speakers differ in the risk of disability pension after first-time sickness absence. This may reveal new aspects how to support health and work ability promotion activities.

Methods:

The longitudinal register data used come from Statistics Finland. They consist of random samples of 5 % of all Finnish speakers and 20 % of all Swedish speakers, observed throughout the period 1989-2010. The analyses concerned non-retired individuals aged 16-60 years who were under risk of first-time sickness absence that extended 10 days. Discrete-time hazard models were estimated to both language groups to evaluate how first-time sickness absence, time since absence, length of absence, and various socio-economic control variables affected the disability pension risk.

Results:

The disability pension risk was extremely high immediately after the sickness absence receipt and remained elevated thereafter approximately 20 times higher as compared to non-recipients. A strong interrelation between first-time sickness absence and the risk of subsequent disability pension was found for both language groups and the risk was persistent in the very long term. The risk pattern looked similar to both Swedish and Finnish speakers and we did not observe any differences between women and men.

Conclusions:

Paid sickness absence is illustrative of strong health selection and a notable risk for reduced work ability even in the more distant future. The currently implemented policies in Finland, which require statements about rehabilitation plans soon after individuals have entered a sickness spell, can be considered beneficial for both the individual and society. Comparison of the language groups shows that the disability pension process after sickness absence is operating similarly to both groups.

Key messages:

- Sickness absence requiring medical certificate is an indicator of possible long-term work disability.
- Timing of rehabilitation process during the sickness absence is critical.

Individual- and company level determinants of vocational rehabilitation: a multilevel study

Mikko Laaksonen

M Laaksonen[1], *J Rantala*[1], *J Liukko*[1], *A Polvinen*[1], *J Varis*[1], *M Kesälä*[1], *S Kuivalainen*[1]
[1]Finnish Centre for Pensions, Helsinki, Finland
Contact: mikko.laaksonen@etk.fi

Backround:

Vocational rehabilitation (VR) is considered an important means to combat work ability problems and enable people to continue working despite health problems. We examined the magnitude of company level variation in VR and determined which individual- and company level characteristics are associated with access to VR due to mental disorders, musculoskeletal diseases, and other somatic diseases.

Methods:

A 30% random sample of all Finnish private sector companies with more than 10 employees aged 25-62 years at the end of 2010 (5.567 companies with 300.601 employees) was followed up for incident VR for six years. Company size and industry, as well as gender, age, education, social class and sickness absence measured both at the individual- and company level, were used as explanatory variables in multilevel logit models.

Results:

After controlling for the individual level covariates, companies accounted for 12% of the variance in VR. The proportion was largest in VR due to musculoskeletal diseases. VR was more common among women, older employees (except the very oldest age group), those with low education (particularly due to musculoskeletal diseases), low social class, and previous sickness absence. VR was more common in larger companies, and in construction and in health and social work, and less common in professional activities. VR was more common in companies with low proportion of highly educated employees and with higher sickness absence rates.

Conclusions:

Company level variation in VR was substantial after controlling for individual level characteristics of the employees. The employer may have an important role in the prevention of work disability through vocational rehabilitation.

Key messages:

- Company level variation in vocational rehabilitation was substantial after controlling for individual level characteristics of the employees.
- The employer may have an important in the prevention of work disability through vocational rehabilitation.

Physicians' use of information from sickness certification guidelines: A nationwide Swedish survey

Veronica Svärd

V Svärd[1]*, K Alexanderson*[1]
[1]Division of Insurance Medicine, Karolinska Institutet, Stockholm, Sweden
Contact: veronica.svard@ki.se

Background:

Sickness certification guidelines, introduced in Sweden 2007, are to support physician's work with sickness certification of patients. Our aim was to explore the clinical importance of the guidelines, by studying what kind of information from guidelines the physicians use, and if this differ between type of clinics.

Methods:

Data from a questionnaire sent to all 34 718 physicians in Sweden in 2017 were used (54% response rate). The study is based on answers from the 13 750 physicians who had sick-leave consultations.

Results:

Half of the respondents used the guidelines at least once a month, and this was most common in primary healthcare (72%), occupational health services (64%) and psychiatry (61%). The type of information used differed; 53% used recommendations about suggested sick-leave duration and 29% about degree (full- or part-time) of sickness absence. Using information about function respectively work capacity was more common within psychiatry (42 and 42%), primary healthcare (37 and 38%) and occupational health services (35 and 41%) and less common among physicians in surgery and orthopaedic clinics (12 and 12%) who more often used information about duration (48 and 53%). In total, 74% reported that the guidelines to some extent were problematic to apply while 29% reported that they improved the quality of how they handled sickness certification tasks. Half (47%) experienced that the guidelines facilitated their contacts with patients.

Conclusions:

The use of sickness certification guidelines varied between type of clinic and a majority experienced to some extent that the guidelines were problematic to apply. Further studies are needed to assess what information physicians in different settings need and what developments of the guidelines that are warranted.

Key messages:

- Half of the physicians used the sickness certification guidelines every month, but the type of information used varied with type of clinical setting.
- As many as half of the physicians stated that the sickness certification guidelines facilitated their contacts with patients, but a majority found them somewhat problematic to apply.

Determinants of managerial preventive actions in relation to common mental disorders at work

Iris van de Voort

IWH van de Voort[1]*, A De Rijk*[1]*, G Hensing*[2]*, M Bertilsson*[2]
[1]Department of Social Medicine, Maastricht University, Maastricht, Netherlands
[2]Institute of Medicine, Epidemiology and Social Medicine, University of Gothenburg, Gothenburg, Netherlands
Contact: i.vandevoort@alumni.maastrichtuniversity.nl

Background:

Managers may prevent Common Mental Disorders (CMDs) among their subordinates due to their authority to influence the work environment. Yet, their perspective has received only limited attention in research. This study aims to increase managers' capacity to contribute to the prevention of CMDs by exploring the determinants of two managerial preventive actions: 'reviewing assignments and the work situation' (MPA-review) and 'taking initiative to talk about depression and anxiety at work' (MPA-talk).

Methods:

An online survey was sent to 4,737 Swedish managers, aged 20-65 years (71% participated, n = 3,358) in 2017, of which 2,921 were included as they answered the MPA-items. Ten possible determinants of MPAs, comprising person-, work-, and competence-related characteristics of managers were related to performing MPAs (yes or no). Bivariate and multivariate binary logistic regression was performed to test associations (OR with 95% CI) between each determinant and MPAs. We have adjusted for experience-related characteristics of managers and company size.

Results:

50% of managers initiated MPA-review and 57% MPA-talk. Managers had a higher odds to initiate respectively MPA-review and MPA-talk when being female (OR 1.42, 95% CI 1.17-1.73; OR 1.33, 95% CI 1.08-1.64), working in organizations offering lectures on CMDs (OR 1.36, 95% CI 1.01-1.83; OR 1.84, 95% CI 1.30-2.60) or stress counselling (OR 1.79, 95% 1.46-2.20; OR 1.53, 95% CI 1.22-1.91), having responsibility for the work environment (OR 1.42, 95% CI 1.15-1.74; OR 1.44, 95% CI 1.16-1.79), or having had received training on CMDs (OR 1.56, 95% CI 1.27-1.93; OR 1.61, 95% CI 1.28-2.03).

Conclusions:

Managers report taking more actions to prevent CMDs in their workforce when they are female, have received training on CMDs or work in organisations where CMD preventive measures have been implemented.

Key messages:

- Organizations could invest in company-wide preventive measures and training to enable MPAs.
- Managerial education should include information on CMDs in order to improve managers' preventive capacity.

Gender differences in managers' attitudes toward depressed employees: a cross-sectional study

Ilaria Mangerini

I Mangerini[1]*, M Bertilsson*[2]*, AE de Rijk*[3]*, G Hensing*[2]
[1]Maastricht University, Maastricht, Netherlands
[2]Institute of Medicine, Epidemiology and Social Medicine, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden
[3]Department of Social Medicine, Research Institute Primary Care and Public Health (CAPHRI), Faculty of Health, Medicine, and Life Sciences, Maastricht University, Maastricht, Netherlands
Contact: ilaria.mangerini@hotmail.it

Background:

Depression is known to carry negative attitudes within society and organisations. In the workplace, managers are responsible for the psycho-social work environment and attitudes to depression will likely affect that environment. The few studies performed among managers have found that female, more educated and managers working in the public sector were less likely to report negative attitudes. However, these studies did not take organization characteristics into account. The aim was to investigate the association between gender and negative attitudes toward employees with depression controlling for individual and organisational factors.

Methods:

A cross-sectional web-survey was sent to 4737 Swedish managers, aged 20-65 years in 2017, response rate 71%; We included those answering the "Managerial stigma toward employee depression" instrument, n = 2663 (901 women, 1762 men), consisting of 12 items tapping negative attitudes towards depression. The 3rd quartile was used as a cut-off. Multivariate logistic regression analyses on attitudes towards depression were performed (95% CI) to generate odds ratios (OR) adjusted for co-variates (individual and organisational characteristics).

Results:

Male managers were more likely to report negative attitudes compared to female managers (OR 1.64, 95% CI 1.28 - 2.10) irrelevant of individual (age, education, current workplace management experience, lifetime experience in management, managerial position) or organisational (work sector, staff gender composition, presence of staff members with Common Mental Disorders) characteristics.

Conclusions:

A gender difference in reporting negative attitudes was appraised regardless any of the co-variates included. To manage depression within the workplace, companies should also address managers' attitudes towards depression.

Key messages:

- Important to heed managers' attitudes to CMDs and their impact on RTW processes.
- Gender-tailored approach in managers' training is suggested for awareness and knowledge on mental health.

Occupational diseases in self-employed workers in France

François Latil

F Latil[1], *B Neme*[1]
[1]Service Medical, Assurance Maladie des Travailleurs Independants, Saint Ouen, France
Contact: fralatil@numericable.fr

Background:

In France, self- employed workers receive disability benefits, but are outside of the specific legislation protecting employees from occupational accident and diseases. Physicians are generally not aware of this shortcoming and ask for occupational diseases benefits, as they do for salaried employees. The health fund of independent workers (HFIW), dismiss the application, which is uphold by law, but can be a threat to the patient, if it shutters hope for other available benefits. Our aim was to see if the request for occupational diseases was related to significant disability in self-employed workers, and if such a disability could be handled by available benefits from HFIW. This survey could be instructive for countries without occupational diseases frame for self-employed workers.

Methods:

A prospective study was conducted on self-employed claimants applying for occupational disease, from June 2015 to September 2017, with an 18 month period follow-up, in the Ile- de- France region. A questionnaire was sent to the claimant and the data were completed through a phone call or appointment. The main outcome was the number of claimants qualifying for disability benefit available at the HFIW.

Results:

148 claimants were identified and 141 (95%) matched with the occupational diseases legal setting. The causative agents were close to those observed in employed workers: musculoskeletal, asbestosis. Disability allowance, complete or partial, could be provided by the HFIW because his criteria were met in 38 claimants(27%);benefits for asbestosis exposure were possible through a specialized body in 16 claimants(11%).

Conclusions:

The occupational disease request from self-employed workers matched with medical conditions granted by the HFIW, or external social bodies. This screening should be routinely implemented by nurses or any insurance officer.

Key messages:

- Self-employed workers are outside of the specific legislation protecting employees from occupational accident and diseases but 27% of them may apply for other disability benefits.
- The occupational disease request from self-employed workers dismiss an application but match with available disability benefits from the Independent health fund and should be routinely screened.

Manager perspectives on workers' return to work after cancer treatment

Steffen Torp

S Torp[1], *Å Valle-Olsen*[1], *B Bruslettto*[1]
[1]Department of Health, Social and Welfare Studies, University South-Eastern Norway, Borre, Norway
Contact: steffen.torp@usn.no

Background:

Due to improved cancer treatment, the survival rate of cancer is increasing Unfortunately, many cancer survivors suffer from serious late effects because of this treatment. Therefore, more and more cancer survivors with reduced work ability are, and will in the future be, in work. To include this group of workers in working life is a challenge for the society in general and for the enterprises in particular. The aim of this study was to investigate managers' experiences regarding cancer survivors' return to work (RTW).

Methods:

We performed qualitative individual in-depth interviews with nine managers who had experience with workers who needed adaptations at work after cancer treatment. The interviews were transcribed in verbatim and thematically analyzed in accordance with guidelines for stepwise deductive-inductive analysis (Tjora, 2016).

Results:

All managers emphasized the importance of taking good care of workers with serious diseases and to adapt work according to their work ability. The managers tried to follow the Work Environment Act and guidelines given by the Norwegian Labor and Welfare Administration but they experienced that the guidelines did not fit well with the needs of the cancer survivor and/or the enterprise. A good RTW process was dependent on an open dialog that was initiated early in the RTW trajectory to establish a sense of safe situation for both the cancer survivor and the company. A good RTW process could only be established if the colleagues of the survivor gave their support to both the survivor and the manager. In addition, it was of great importance that the needs of the cancer survivor had to be balanced by the production needs of the enterprise.

Conclusions:

Managers need support from health personnel and social security agencies to support cancer survivors to retain work.

Key messages:

- Cancer survivors need adaptations at work.
- Managers are crucial in securing a successful vocational rehabilitation of cancer survivors.

Topic modeling to mind illegal compensation for occupational injuries

Sung-Hee Song

SH Song[1], *JY Min*[2], *HJ Kim*[1], *KB Min*[1]
[1]Preventive Medicine, Seoul National University, Seoul, South Korea
[2]Health and Environment, Seoul National University, Seoul, South Korea
Contact: clastro@snu.ac.kr

Background:

Accurate reports of occupational injuries are important to monitor workplace safety and health initiatives. In South Korea, media reports, experts, and workers have been constantly raising the issue of underreporting. Supposedly it is because employers have strong market "incentives" by underreporting their employees' injuries. A critical way to underreport or cover-up is illegal compensation (in Korean called "gong-sang"). Unfortunately, "gong-sang" is not counted as official occupational injury statistics. The aim of this study was to analyze the social media data using topic modeling and to explore issues surrounding "gong-sang".

Methods:

We used web scraping technology and collected 2,210 social media data from Web search engines. Data was processed to transform unstructured textual documents into structured data using the Python and applied Latent Dirichlet allocation (LDA) in the Python library, Gensim, for topic modeling.

Results:

Based on the LDA method from ''gong-sang''- related documentation, 10 topics were identified. Topic 1 was the greatest concern (60.5%), with keywords implying the choice between illegal compensation (''gong-sang'') and legal insurance claims. The next concern was Topic 2 including keywords associated with claims for industrial accident insurance benefits. The rest topics (topic 3-10) showed the monetary issue, precarious employment, and vulnerable body parts to ''gong-sang''.

Conclusions:

We explored web-based data and identified the salient issues surrounding ''gong-sang''. LDA topics may be helpful to ensure efficient occupational health and safety scheme to protect vulnerable employees from ''gong-sang'' practices.

Key messages:

- The topics formulated by LDA included queries about legal insurance claims.
- Legal insurance claims including private or social insurance, monetary compensation, injured body parts, and the type of jobs vulnerable to ''gong-sang''.

Work capacity assessments – reviewing the what and how of physicians' clinical practice

Paula Nordling

P Nordling[1,2]
[1]Department of Public Health and Community Medicine, University of Gothenburg, Gothenburg, Sweden
[2]Primary Health Care, Region Västra Götaland, Gothenburg, Sweden
Contact: paula.nordling@gu.se

Background:

Although a main task in the sickness certification process, physicians' clinical practice when assessing work capacity has not been thoroughly described. Increased knowledge on the matter is needed to support a better and more reliable certification process. In this review, we aimed to synthesise existing evidence to provide a clearer description of the work capacity assessment as practiced by physicians.

Methods:

Seven electronic databases were searched systematically for qualitative studies examining what and how physicians do when they assess work capacity. Data was analysed and synthesised using qualitative manifest content analysis.

Results:

Twelve articles were included in the review. Results show that physicians seek to form a knowledge base including understanding the condition, the patient and the patient's workplace. They consider both medical and non-medical aspects to affect work capacity. Accordingly, to acquire and process the information they use both medical and non-medical skills, methods and resources. Medical competence is an important basis, but not enough. Time, trust, intuition and reasoning are also used to assess the patient's claims and to translate the findings into a final decision. The depth and focus of the information seeking and processing vary depending on several factors.

Conclusions:

The work capacity assessment is a complex task where physicians rely on their non-medical skills to a higher degree than in ordinary clinical work. These skills are highly relevant but need to be complemented with methods to better understand the patient's work place, as well as theoretical knowledge regarding the intricate associations between health, work and social security. This would further enhance physicians' competence and confidence, and promote better experiences and practices of the work capacity assessment.

Key messages:

- In the complex task of assessing work capacity physicians rely on their non-medical skills to a higher degree than in ordinary clinical work.
- A better understanding of the patient's work situation and the intricate associations between health, work and social security would enhance physicians' competence and promote better assessments.

The effects of skill-based team learning curriculum in workplace violence prevention for nurses

Min-Chien Tsai

F-L Chen[1], *P Chen*[2], *T-Y Kuo*[1], *S-Y Chiou*[3]
[1]Department of Public Health, Fu-Jen Catholic University, New Taipei City, Taiwan
[2]Department of Psychology, Auburn University, Auburn, USA
[3]Department of Leisure Industry and Health Promotion, National Ilan University, Ilan, Taiwan
Contact: mctsai.cc@gmail.com

Background:

Workplace violence, faced by health care workers, is a severe occupational safety and health hazard, and has received global attentions in research and in practice. The aim of this study was to design, implement, and evaluate a skill-based team learning curriculum of violence prevention for clinical nurses.

Methods:

78 clinical nurses were purposively selected including 41 nurses of treatment group, and 37 nurses of control group. Each treatment group received the training curriculum which included three sessions: (1) 50-minutes workplace violence lecture and video to illustrate the various workplace violence situations, (2) 50-minute team group discussion to design effective violence prevention skills for a hospital violence situation, (3) 60-minute interactive skills training curriculum focusing on role play, rehearsal and feedback. The control group only received a self-learning violence prevention manual. Generalized Estimating Equation (GEE) model was used to examine the program effects.

Results:

The results for the GEE statistics indicated a significant time effect. The pretest-posttest and after the posttest results that treatment group showed significant improvement in preventive skills ($\beta = 1.828$, $\beta = 1.330$; $p<0.001$) and self-efficacy($\beta = 4.123$, $\beta = 5.363$; $p<0.001$) compared to the control group. Besides, the experimental group significantly decreased incidents of verbal violence ($\beta = -1.140$, $p < 0.05$) compared to the control group.

Conclusions:

The study showed integration of skill-based teamwork learning in clinical nursing training provides an additional venue to prevent and reduce workplace violence. This shall be a feasible module and significant reference in junior or pre-service health care workers training in the future.

Key messages:

- The study demonstrates the feasibility of implementing the team learning curriculum for clinical nurses.
- The present study provides empirical evidence of the skill-based team learning training curriculum in workplace violence program for clinical nurses.

Psychosocial working conditions and future sick leave and disability pension trajectories in Sweden

Laura Salonen

L Salonen[1], *K Alexanderson*[2], *R Rugulies*[3], *E Framke*[3], *M Niemelä*[1], *K Farrants*[2]
[1]Sociology, Department of Social Research, University of Turku, Turku, Finland
[2]Division of Insurance Medicine, Department of Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden
[3]National Research Centre for the Working Environment, Copenhagen, Denmark
Contact: lksalo@utu.fi

Background:

Psychosocial working conditions such as job demands and job control have been found to be associated with employee health and well-being, but studies on the associations with sickness absence (SA) and disability pension (DP) are scarce. We examined 11-year SA/DP trajectories and the association between psychosocial working conditions and subsequent SA/DP trajectories in the Swedish workforce.

Methods:

Using a prospective cohort study with microdata we explored SA/DP trajectories among female and male employees, respectively, aged 30-53 years in 2001 in Sweden (1,076,042 women; 1,102,721 men). Group-based trajectory analysis was used to model annual mean SA/DP net days trajectories in 2002-2012. Based on a Swedish Job Exposure Matrix (JEM), individuals were assigned an age-, sex- and occupation-specific mean score for demands and control, respectively. Mean scores were categorized into tertiles and categorised into 3x3 combinations of exposure categories. Using multinomial regression we predicted trajectory group memberships for the JEM.

Results:

The highest rate of women were in occupations with low demands and control (24.8%), while the highest rate of men (22.9%) was in occupations with high demands and control. We found three SA/DP trajectories for women (low, medium, high increasing) and two for men (low, high increasing). In fully adjusted models, those in occupations with low demands and low control were at higher risk of belonging to the high increasing SA/DP trajectory compared to those in occupations with high job demands and control in both women (OR 3.86; 95% CI: 3.75-3.97) and men (OR 3.0; 2.99-3.16).

Conclusions:

Low job demands and low job control were associated with more high increasing future SA/DP trajectories compared to high job demands and job control in both women and men.

Key messages:

- In Sweden, women are more often in occupations characterized by low job demands and low job control and men are more often in occupations with high job demands and high job control.
- Occupations with low job demands and low job control were associated with more adverse SA/SP trajectories compared to occupations with high job demands and high job control in both women and men.

Approach for Compensation System of Asbestos-Related Lung Cancer

Yuka Nishina

Y Nishina[1,2], *M Niino*[1], *T Higashi*[1]
[1]Division of Health Services Research, National Cancer Center Japan, Tokyo, Japan
[2]Health Division, Employment, Labour and Social Affairs, Organisation for Economic Co-operation and Development, Paris, France
Contact: yukayuka0510@gmail.com

Background:

The health hazards of asbestos have been globally recognized, especially those among industrial workers with long-term exposure. Lung cancer is one such asbestos-related disease. It occurs not only among workers but also among residents with environmental exposure to asbestos. Patients with work-related exposure can receive occupational compensation, and patients with non-occupational exposure are supported by a separate compensation system in Japan. However, the latter is not well-known among clinicians, and a substantial number of patients may have been left out. We need an effective way to find patients eligible to receive benefits by better understanding the clinical conditions that characterize patients with asbestos-related lung cancer.

Methods:

We conducted two types of research: 1. Comparison of clinical characteristics between compensation system recipients (N = 65) and general lung cancer patients diagnosed in 2015, using Japan's National Database of Hospital-Based Cancer Registry.

2. Estimation of the frequency of pleural plaques among lung cancer patients by double-checking CT scan images of a random sample of lung cancer patients obtained from the HBCR national database (N = 3585).

Results:

1. Patients with squamous cell carcinoma are twice as likely asbestos-induced as patients with other histology overall after adjusting for age, sex and cancer stages, but not smoking status and history.
2. As many as 20% of the CT images were read inconsistently between two radiologists or respiratory disease doctors and we could not obtain the accurate rate of candidacy for the compensation system.

Conclusions:

We require more accurate information about pathological characteristics by controlling for smoking status and history among compensation recipients. For radiologic interpretation, more effective education is needed for the radiologists and respiratory disease doctors who treat lung cancer patients.

Key messages:

- Specific information about asbestos-related lung cancer would lead clinicians to correctly identify asbestos-related lung cancer.
- Educational system for clinicians would help patients to receive the benefit of compensation.

Predicting occupational exposure to trace metals from welding by non-air monitoring based models

Fatma Omrane

F Omrane[1,2], *I Gargouri*[1,3], *M Khadhraoui*[1], *B Elleuch*[1], *D Zmirou-Navier*[2,4]
[1]Laboratory of Environmental Engineering and EcoTechnology, University of Sfax, Sfax, Tunisia
[2]Medical School, Lorraine University, Vandœuvre-les-Nancy, France
[3]Medical School, University of Sfax, Sfax, Tunisia
[4]U1085, INSERM, Rennes, France
Contact: fatma.omrane@eleve.ehesp.fr

Mathematical models for estimating occupational exposure to chemicals were developed as a promising alternative to air monitoring that is pricey and sometimes unavailable. Still, models parameters are derived from former air monitoring. Contrarily, our study aims to calculate all parameters independently of monitoring data. We implemented this approach to assess exposure in welding plants. Then, prediction abilities are evaluated by comparison with air measurements.

The Near Field-Far Field (NF-FF) model seeks to give accurate exposure estimation near an emission source. One workplace includes Shielded Metal Arc Welding (SMAW) worker T1 who is in the NF. The other contains induction welding (IW) T2 and packaging workers T3 who are in NF and FF, respectively. The emitted metals are identified from materials compositions. Ventilation rates are calculated by the anemometer technique. Emission rates are calculated using the emission factor method for SMAW and mass balance method for IW, solely based on literature, materials quantities and their compositions. To evaluate the match between measured (6 replicates) and predicted levels, we checked their correlations and tested the mean differences of paired values.

T1 is exposed to Al, Cu, Ni, Cr and Pb, while T2 and T3 are exposed to Al, Cu, Ni, Cr and Zn. A strong correlation was found ($r = 0.78$, $p = 0.008$) for NF predictions and air measurements. The T-test was significant, confirming that NF predictions and measured levels are quite close.

In contrast, our approach did not succeed to predict the FF exposure (insignificant correlation), which is probably due to the mobility of T3.

Non-air monitoring based models showed good effectiveness to predict the exposure levels close to emission sources for SMAW and IW processes. Thus, to assess health risks or to evaluate compliance with workplace air standards, our modeling approach that is time and cost saving, can be adopted as a support tool or even an alternative to air monitoring.

Key messages:

- With a view to assess occupational exposure, non-air monitoring based models, that are time and cost saving tools, showed good prediction abilities for trace metal levels near welding emission sources.
- The use of non-air monitoring based models would help to control the working environment of occupationally exposed populations to welding fumes, which is useful to comply with air quality standards.

An investigation of putative exposure of staff to novel psychoactive substances in a prison

Kate Mark

K Mark[1], C Waugh[1], D McCormick[1], J Joyce[2]
[1]Health Protection Team, NHS Lothian, Edinburgh, UK
[2]Justice Services, Sodexo, Edinburgh, UK
Contact: kate.mark@nhslothian.scot.nhs.uk

Issue:

In a prison in Scotland, an increasing number of incidents occurred where staff became unwell secondary to potential exposure to novel psychoactive substances (NPS) smoked by prisoners. There were high levels of concern for the safety of individual staff, and for establishment staffing. NPS use is a significant problem in custodial settings, and impacts individuals and establishments.

Methods:

HMP and HPT led an incident response: HMP focused on prevention and direct management of incidents; HPT focused on exposure circumstances, clinical presentation and toxicological testing of symptomatic staff. A protocol was agreed between all agencies involved. Over 8 months, all incidents' initial assessment and any subsequent clinical and toxicological results were collated and analysed by HPT.

Results:

There were 19 incidents involving 16 staff members. Cases presented in clusters, in one instance 13 people presented over 5 days. Five presented in early 2018.

Individuals reported a wide range of non-specific physical and psychological effects; some cases experienced severe impairment of day-to-day function. The most common effects were headache and fatigue but some reported sleep disturbance and confusion lasting up to 72 hrs. There were no significant clinical observations at hospital, and the 3 tests for toxicology were negative.

Lessons:

The individuals affected by these incidents experienced physical and psychological distress, and impairment of daily functioning which impacted on the safe function of the establishment. It is unlikely staff presentations were due to toxicological effects from substances used by prisoners. It is possible their symptoms were psychosomatic. This could be further investigated, and consideration given to supportive intervention for staff affected by exposure to NPS. The investigation demonstrated excellent collaborative work between the prison, health services, and forensic laboratories in a novel investigation into NPS exposure in prisons.

Key messages:

- NPS use, and subsequent exposure to staff, is a growing issue in custodial settings.
- A combination of supportive interventions for staff, including reduction and mitigation of risk of exposure to NPS, plus control of substances use in prisons can help.

Life style habits of truck drivers in France

Virginie Bourdin

V Bourdin[1], G King[2], L Josseran[1,3]
[1]Public Health Department, AP-HP, Raymond Poincaré Hospital, Garches, France
[2]Department of Behavioral Health, Pennsylvania State University, State College, PA, USA
[3]UFR Simone Veil, Versailles-Saint Quentin University, Montigny-le-Bretonneux, France
Contact: virginie.dufauret@gmail.com

Background:

European truck drivers' (TD) lifestyle behaviors is a topic of great interest but not frequently studied. Unhealthy behaviors such as smoking, alcohol consumption, drug abuse or a lack of physical activity infer a greater risk for cardio-vascular diseases and road accidents. This study aimed at describing life TD habits.

Methods:

A prospective cross-sectional study was conducted in April 2018 on 4 rest areas with the support of the nonprofit organization ''Fondation VINCI Autoroutes pour une Conduite Responsable''. 515 TD were interviewed randomly at 4 highway rest stops. Life habits data were collected and analysis was conducted using univariate statistics.

Results:

38.6% (n = 199) declared to be daily smokers, with no significant difference when reported to nationality or age. 24.6% (n = 126) are normal weighted, while 72.4% (n = 373) have a BMI superior to 25. 58.8% (n = 303) of the TD drink alcohol on a regular basis, and 8.5% of them (n = 26) on a daily basis. High blood pressure is significatively associated with alcohol consumption (5.2% vs. 12.9%, $p < 0,05$) and obesity (19.4 % vs. < 10%, $p < 0,001$). 2.5% (n = 13) of the TD consume psychoactive drugs, most of them cannabis. As concerns diet: 32.8% (n = 169) consider it as balanced, 32.6% (n = 168) not balanced, and 34,6% can't qualify it. When TD think their diet is unbalanced, they judge it too fat (75.6%), too sweet (61.9%) or too salty (50.6%).

Conclusions:

The most striking results concern TD expectations, since 41.7% of the daily smokers and 5.3% of the alcohol consumers would be interested in help measures to stop. TD with the highest BMI are the most demanding for a diet help. Motorway operators, unions and compagnies should fulfill these expectations, since TD in better health are less frequently involve in road accidents. TD spend a lot of time on rest area and this offers interesting periods of time to develop health education specifically for them.

Key messages:

- Many truck drivers prove to be daily smokers and/or with excess weight, and/or eating an unbalanced diet. High blood pressure is significatively associated with alcohol consumption and obesity.
- Expectations are high as concerns help measures to reach healthier behaviors and live a better life.

Lung cancer screening by low-dose CT among asbestos-exposed workers: first results of a pilot program

Jan Heidrich

J Heidrich[1], C Wolff[2], A Centmayer[2], T Wiethege[3], M Duell[4], D Taeger[3], V Harth[1]
[1]Institute for Occupational and Maritime Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany
[2]Gesundheitsvorsorge (GVS), Augsburg, Germany
[3]Institute for Prevention and Occupational Medicine, German Social Accident Insurance (DGUV), Institute of the Ruhr-University, Bochum, Germany
[4]Insurance Law, German Social Accident Insurance (DGUV), Berlin, Germany
Contact: jan.heidrich@bgv.hamburg.de

Background:

Occupational asbestos exposure (OAE) is a risk factor for lung cancer (LC) and can cause malignant diseases decades after exposure. Lung cancer screening with low-dose computed tomography (LCS) in heavy smokers has shown LC-mortality reductions in two large trials. Recent guidelines advocate LCS in high-risk populations with OAE and additional smoking history.

Methods:

A structured pilot program on LCS in three German regions has been implemented from 2014 to 2018. Eligibility criteria are: OAE $\geq$10 years starting before 1985 or diagnosis of OAE-related lung disease other than cancer, age $\geq$55 years and smoking history $\geq$30 pack years. Eligible persons are centrally invited for LCS on a voluntary basis in 12 months intervals. All persons willing to participate receive obligatory physician counselling before LCS. CT scans are performed according to a standardized protocol. The program provides technical quality assurance as well as independent double reading of all suspicious findings and of a random sample of all CT scans.

Results:

Of 2715 and 1534 persons invited to first and second LCS, 1571 (57.9%) and 715 (46.6%) agreed to participate, respectively. Main reason for disagreement was principal refusal of LCS (15.5% in first and 22.2% in second LCS), whereas 8.5% and 6.9%, respectively, refused after counselling. Additionally, 12.9% and 5.7% did not respond at all. Effectively, 68.8% and 70.6% of those who initially agreed, received first and second LCS, respectively. Variations between regions were observed (range 61.0% to 79.8%). First preliminary outcome assessment shows detection rates of 0.019 and 0.011 in first and second LCS, respectively.

Conclusions:

A substantial group of eligible persons with OAE participated in LCS after physician counselling. Participation remained stable over two screening rounds. First results show detection of LC in the expected range. The effectiveness of early detection of LC in OAE needs to be evaluated further.

Key messages:

- Participation over the first two screening rounds in structured lung cancer screening remained stable among eligible persons with OAE and smoking history who were counselled by physicians.
- Detection of lung cancer in a structured pilot screening program in three German regions seems to be within the range to be expected from previous research.

The barriers of workplace safety and health management: from the supervisor's perspective

Min-Chien Tsai

M Tsai[1], *F Chen*[2], *P Hsu*[2], *C Chen*[2]
[1]Department of Psychology, Fu Jen Catholic University, New Taipei City, Taiwan
[2]Department of Public Health, Fu Jen Catholic University, New Taipei City, Taiwan
Contact: mctsai.cc@gmail.com

Background:

Previous researches demonstrated that workplace safety and health (WSH) management plays a major role in promoting worker's health and well-being. However, organizational factors hinder promoting WSH management program. The main aim of this study is to explore the probable existence of barrier from WSH supervisor's perspective.

Methods:

This study employed a qualitative design to gain an in-depth and holistic understanding of WSH from the supervisor's perspective. Eight focus groups were conducted in Taiwan. A total of 81 supervisors (employer, human resource section, environmental safety section) from the manufacturing industry, construction industry, and service industry participated in this study. All interview contents were transcribed and coded. Matrices were constructed to identify themes and evolving concepts.

Results:

Three main barriers were identified1. Lacking of top management commitment and support (e.g., top management focused more on employees' work performance than their safety and health, top management commitment was just a declaration but with no action, and top management only conducted the traditional occupational hazards control to fit the minimum standards of national policy, and ignored employees' mental health and well-being); 2.Lacking of employee's safety awareness (e.g., employee lacked the motivation to attend training program; 3.Organizational resources were not enough to implement occupational safety and health management (e.g., the supervisor lacked professional skills in promoting WSH program).

Conclusions:

The study findings provide an integrated basis for practical application and further research. The workplace supervisor should be trained the professional skills in workplace safety and health management. Then, the workplace psychosocial safety climate can be built while top management and employee have higher workplace safety and health awareness.

Key messages:

- This study contributes to occupational health research from the supervisor's perspective.
- This study also hints at the potential role of top management promoting employee's health and well-being.

Sexual harassment at work: Design of a new questionnaire to measure sexual harassment

Maj Britt Dahl Nielsen

MBD Nielsen[1], *IEH Madsen*[2], *T Clausen*[2], *SS Skov*[1], *S Kjær*[3], *LV Kvorning*[4], *PT Aldrich*[5], *R Rugulies*[2], *AP Folker*[1]
[1]National Institute of Publich Health, University of Southern Denmark, Copenhagen, Denmark
[2]The National Research Centre for the Working Environment, Copenhagen, Denmark
[3]Arbejdspsykologisk Praksis, Herlev, Denmark
[4]COWI, Kongens Lyngby, Denmark
[5]NIRAS, Allerød, Denmark
Contact: mbdn@si-folkesundhed.dk

Background:

Sexual harassment is a complex phenomenon and our knowledge is hampered by a lack of consensus on the definition and measurement. However, workplaces need reliable instruments that provide a nuanced understanding of sexual harassment and input for action to mitigate negative consequences. The aim of this project is to help workplaces prevent and manage sexual harassment, which include developing a new and comprehensive instrument to monitor sexual harassment (Inventory of Workplace Sexual Harassment). In this abstract, we explain the process of designing the questionnaire.

Methods:

The design process follows three steps: (1) Identification of a theoretical and conceptual framework, (2) item development and (3) field testing. First, we identified relevant theoretical and conceptual frameworks, which we discussed with an expert group consisting of researchers and stakeholders (employer and trade unions). Second, we developed items based on expert inputs and previous surveys. We adapted the first version of the questionnaire following a feedback round with the expert group. Third, we will complete field testing in 2019-2020. Field testing encompasses cognitive interviews (n = 15) and in-depth interviews with men and women exposed to sexual harassment to assess clarity and relevance (in 2019), and a pilot study at 15 workplaces to assess prevalence and usability (in 2020).

Results:

Based on the theoretical and conceptual model from Fitzgerald et al, we developed a preliminary version, consisting of 22 items that cover three domains: (1) unwanted sexual attention, (2) gender harassment and (2) sexual coercion. The survey draws on questions from SEQ-DoD and Bergen Sexual Harassment Scale. Results from field testing will be available for the conference.

Conclusions:

The Inventory of Workplace Sexual Harassment will provide a comprehensive and validated measurement of workplace sexual harassment and will help workplaces prevent and manage sexual harassment.

Key messages:

- Sexual harassment is a complex and multifaceted phenomenon, but our knowledge is hampered by a lack of consensus on the definition and measurement.
- This study contributes with a new instrument measuring the prevalence of workplace sexual harassment and tools for prevention and management of sexual harassment.

DK Health at work, Social security

Two step cluster analysis of burnout among preschool teachers

Jovana Todorovic

P Piperac[2], *Z Terzic-Supic*[1], *J Todorovic*[1], *A Maksimovic*[3], *S Karic*[3], *I Soldatovic*[4]

[1]University of Belgrade, Faculty of Medicine, Institute of Social Medicine, Medical Faculty, Belgrade University, Belgrade, Serbia
[2]University of Belgrade, Faculty of Medicine, Department of humanities, Belgrade, Serbia
[3]The college for preschool teachers, Sabac, Sabac, Serbia
[4]University of Belgrade, Faculty of Medicine, Institute for medical statistics and informatics, Belgrade, Serbia
Contact: jovana.todorovic@med.bg.ac.rs

Background:

The burnout is influenced by a variety of personal, work-related and client-related factors, which are included in different domains of Copenhagen burnout inventory (CBI). The aim of this study was to examine if there are different groups of preschool teachers which differ in scores on different domains of CBI.

Methods:

This was the analysis of the data from the survey on burnout on a National representative sample of 456 preschool teachers in Serbia. The study was conducted between October of 2018 and January 2019. The study instrument contained questions on socio-demographic characteristics, workplace environment characteristics, and Copenhagen burnout inventory. We used two-step cluster analysis in SPSS to segment the participants based on age and average scores on personal, work-related and client related domains of CBI.

Results:

Our participants clustered in three distinguished groups: participants aged 35.31 years, who worked in shifts, with personal burnout average of 29.46, work-related burnout average of 24.06 and client related burnout average of 19.46; participants aged 44.09 years, who worked in shifts, personal domain scores of 55.24, work-related burnout scores of 51.72, and client-related burnout scores of 51.13; and participants aged 43.01 years, who did not work in shifts, with personal burnout scores of 36.47, work-related burnout scores of 31.95, and client-related burnout scores of 32.08.

Conclusions:

Participants clustered in three different groups, and the group with the highest average age and with the shift work had higher scores on all three domains compared to other groups.

Key messages:

- Preschool teachers clustered in three groups with different scores on domains on burnout.
- The group with the highest average age had the highest scores on all three domains of burnout.

Occupational Eye Trauma: a major public health issue in Rabat, Morocco

Yassine El Harrak

Y El Harrak[1], *N Boutimzine*[1], *LO Cherkaoui*[1]

[1]Ophtalmologie A, Faculté de médecine et de pharmacie de Rabat, Rabat, Morocco
Contact: elharrak.yass@gmail.com

Occupational eye trauma is a global cause of visual morbidity. According to the WHO, 55 million ocular lesions occur each year, and 1.6 million cases of total blindness caused by trauma. Although common in Morocco, these traumas have not been the subject of recent and targeted investigations.

The objective of our work is to evaluate the frequency of occupational eye trauma per projectile, and to encourage the reinforcement of safety measures. This is a cross-sectional descriptive study, carried out in the Ophthalmic Emergency Department, at the University Hospital of Rabat, Morocco, and including all patients who presented to the same doctor's consultation, between December 2016 and December 2018. The study involved 914 patients, 406 women and 508 men, with an average age of 36. The average consultation time is 35 days after the onset of symptomatology.

In 2 years, and out of 914 people, 382 (42%) are victims of ocular trauma; and 167 are victims of projectile eye trauma during professional practice, an overall prevalence of 18%, or 51% of all trauma.

The average age was 32 years, 92% of males. The average consultation time was 2 days after the accident. In addition, 75% of consultants for occupational eye trauma have a similar history of trauma, 3 out of 4 people. As a consequence, the study shows that 85% of these patients had a superficial corneal foreign body; 11% presented with a corneal ulcer without individualization of a foreign body; while 4% of these had a corneal wound, an intraocular foreign body and posttraumatic retinal detachment. Therefore, eye trauma is a real public health problem. They account for 42% of consultations, half of which are associated with professional activities, mainly affecting young and active men. If they are benign in most cases, these traumas can nevertheless cause blindness in 4%.

The high number of recidivism (75%) highlights the lack of awareness of the target population for better prevention.

Key messages:

- The results of this work prove that occupational ocular trauma, avoidable circumstances, are however frequent in our context and can cause severe lesions, with a reserved prognosis.
- Workplaces with a high risk of eye trauma should strengthen their protective measures and training programs should be put in place for both workers and occupational physicians.

Diurnal rhythms of cortisol and melatonin in night eating and non-night eating male police officers

Jeppe Karl Sørensen

JK Sørensen[1], *MA Jensen*[1,2], *ÅM Hansen*[1,2], *R Rugulies*[1,2,3], *AH Garde*[1,2]

[1]The National Research Centre for the Working Environment, Copenhagen, Denmark
[2]Department of Public Health, University of Copenhagen, Copenhagen, Denmark
[3]Department of Psychology, University of Copenhagen, Copenhagen, Denmark
Contact: jks@nfa.dk

Background:

Working during the night has in previous studies been associated with behavioural changes and diseases. Disturbance between behavioural and biological circadian rhythms have been suggested as a possible mechanism linking night work with cardiovascular diseases and pre-diabetic changes. The aim of this study was to investigate if night eating during two, four and seven consecutive night shifts is associated with differences in the diurnal rhythms of cortisol and melatonin in male police officers in Denmark.

Methods:

We conducted an experimental study among 37 male police officers in Denmark who all collected data on the last night shift in three different work schedules with two, four and seven consecutive night shifts, respectively. Night eating was self-reported and defined as eating at least one main meal between midnight and early morning. Differences in the diurnal rhythms of concentrations of cortisol and melatonin in saliva were tested by phase changes and amplitude differences.

Results:

Sixteen (43.2%) police officers ate a main meal during the last night shift in all three work schedules. The timing of the lowest cortisol concentration was on average delayed with 2:10 hours (95% CI 0:24-3:56 hours) and the level of the lowest cortisol concentration was on average supressed with 66% (95% CI 47-94%) for night eaters compared to non-night eaters. There was no association with number of consecutive night shifts. The phase and amplitude of melatonin were not statistically significantly different between night eaters and non-night eaters.

Conclusions:

Night eating behaviour is associated with differences in the diurnal rhythm of cortisol in Danish male police officers working during the night. The difference in cortisol rhythm between night eaters and non-night eaters on night shifts is not affected by the number of consecutive night shifts.

Key messages:

- Night eating behaviour is associated with differences in the diurnal rhythm of cortisol.
- Future studies should focus on potential health outcomes of night eating behaviour among night workers.

Attitudes of Polish employers towards smoking/e-cigarette use in workplaces

Grzegorz Juszczyk

L Balwicki[1,2], G Juszczyk[2], A Dela[2], A Tyranska-Fobke[1]
[1]Department of Public Health and Social Medicine, Medical University of Gdansk, Gdansk, Poland
[2]National Institute of Public Health, Gdansk, Poland
Contact: dyrektor@pzh.gov.pl

Background:

For many years Poland has been undertaking initiatives aimed at reducing the problem of smoking among citizens. Many educational and legislative activities have been carried out. One of them was introduction of smoking ban in workplaces and other public places in 2010. The aim of the was to look for attitudes of Polish employers towards smoking and e-cigarette use in workplaces.

Methods:

The cross-sectional survey was carried out on representative group of 2,501 employers from Poland in July/August 2018. Respondents answered to the original questionnaire with help of Computer Assisted Telephone Interview (CATI) method. Questionnaire consisted of 19 questions regarding attitudes towards smoking and e-cigarettes use in their workplaces. Data were analyzed with the help of descriptive statistics, correlation analysis methods. Statistical significance was set at $p < 0.05$.

Results:

Only 44.9% employers agree they should not take care for creation conditions for smoking tobacco/e-cigarettes use during working hours. The majority of respondents (53.7%) believe that non-smokers (without going out to smoke) have fewer breaks in their work. In addition, 51.8% of respondents believe that smoking tobacco/e-cigarettes by employees brings economic losses to the company, and 55.0% think that smoking tobacco/e-cigarettes use during work spoils the company's image. At the same time, as many as 88.5% of respondents indicated that their workplaces did not carry out activities encouraging them to quit in the last two years and 52.8% do not believe in their effectiveness.

Conclusions:

Although respondents indicated the negative consequences for their companies because of tobacco smoking/e-cigarettes use by employees, the majority of employers do not take actions to reduce this problem. As big part of them sees also economical and image problems they should be supported in their activity to reduce the tobacco/e-cigarette use among employees.

Key messages:

- Employers see economical and image problems cause by smoking/e-cigarette using employees.
- Employers should be supported by public health professionals as they do not believe nor undertake effective activities to reduce tobacco smoking/e-cigarettes use.

A taxonomy of mechanisms underpinning the impact of welfare rights advice on health

Monique Lhussier

N Forster[1], M Lhussier[1], C Woodhead[2], A Barnes[3], SM Carr[1], K Haighton[1]
[1]Faculty of Health and Life Sciences, Northumbria University, Newcastle upon Tyne, UK
[2]Institute of Epidemiology & Health, University College London, London, UK
[3]School of Health and Related Research, University of Sheffield, Sheffield, UK
Contact: monique.lhussier@northumbria.ac.uk

Background:

Welfare rights advice has potential to help address the social determinants of health and reduce inequalities. Existing logic models identify the sequence of proximal to distal outcomes following welfare advice, but attribution remains challenging. This paper reports on the contextual influences and key mechanisms leading to health outcomes.

Methods:

We undertook comprehensive searches of the literature addressing the links between welfare advice and health. Titles and abstracts were screened first, then full text, using inclusion and exclusion criteria. Employing a realist logic of analysis, data extraction and synthesis focused on disentangling evidence of how and why advice improves (or not) health related outcomes, depending on the context. These insights were then paired with existing theory (either explicitly referenced or inferred by authors), in order to produce a robust explanatory model of when and how advice leads to improved health.

Results:

59 articles were included in the analysis. Preliminary findings point to the significance of target group in influencing the types of outcomes achieved. Fineman's (2013) typology of embodied, situational and structural vulnerability helped explain the differential impact of advice. Where people experience embodied vulnerabilities, such as life-limiting illness or disabling physical or mental health conditions, advice may increase quality of life, but is less likely to improve existing health status. Likewise, advice interventions alone are unlikely to alter health outcomes stemming from entrenched structural disadvantages such as poverty or discrimination, and appear to be most effective in addressing situational vulnerabilities generated more temporarily by difficult circumstances.

Conclusions:

The review provides a more nuanced understanding of how and why welfare advice may impact on health. These insights will help to more appropriately target, tailor and monitor the health impact of welfare advice.

Key messages:

- Welfare advice has differential impact, depending on specific client vulnerabilities.
- This highlights the importance of appropriate targeting, and selecting suitable measures of success.

Setting the agenda for further research on health and welfare

Monique Lhussier

M Lhussier[1], *N Forster*[1], *K Haighton*[1], *M Egan*[2], *C Woodhead*[3], *C Webb*[4], *L Poole*[5], *SM Carr*[1], *S Dalkin*[1], *H Brown*[6]
[1]Faculty of Health and Life Sciences, Northumbria University, Newcastle upon Tyne, UK
[2]Department of Health Services Research and Policy, LSHTM, London, UK
[3]Institute of Epidemiology & Health, University College London, London, UK
[4]Department of Sociological Studies, University of Sheffield, Sheffield, UK
[5]Advice Services Alliance, London, UK
[6]Institute of Health and Society, Newcastle University, Newcastle, UK
Contact: monique.lhussier@northumbria.ac.uk

Background:

Given the recognised relationship between poverty, welfare provision and health, welfare rights advice has emerged as a potentially key intervention in improving health and reducing inequalities. The generation of evidence in this area has proven difficult however, creating a need to take stock of existing research and develop an agenda for future work.

Methods:

A series of four workshops was convened involving researchers from four UK universities who had previously undertaken work examining the relationship between welfare advice and health, from a range of methodological perspectives. Run concurrently to a scoping of the literature, these workshops aimed to synthesise lessons from prior research; formulate outstanding research questions; and outline potential methodological approaches for addressing these. A survey was undertaken with professionals (from welfare or legal advice sectors, the health sector, commissioning, local government, and housing services, n = 50) to test out, refine and add to these research questions.

Results:

Key research questions developed from these workshops were:

- Are there inequalities in the impact and reach of advice services across social groups? How/ does advice delivery mode matter?
- What are the individual and system level impacts of the de-implementation of advice services?
- What are the impacts of changes to welfare provision on children, inter-generationally and throughout the life course?
- How do experiences of social welfare vary by social group, geographically and across generations? How do different identities combine to influence how social welfare is understood?

Conclusions:

While the collaborative process brought challenges in balancing research and practitioner expertise, this model of working has been successful in setting an agenda for further research with maximum utility to practice. Direct outputs from the projects have been the collaborative submission of a journal article and a research bid.

Key messages:

- The collaboration, which was supported by the NIHR School of Public Health Research, led to the establishment of a concise research agenda.
- Through extensive stakeholder consultation, this will have maximal utility for practice.

Trajectories of musculoskeletal pain among midlife employees

Subas Neupane

S Neupane[1,2], *T Lallukka*[2,3], *O Pietiläinen*[3], *O Rahkonen*[3], *P Leino-Arjas*[2]
[1]Unit of Health Sciences, Tampere University, Tampere, Finland
[2]Finnish Institute of Occupational Health, Helsinki, Finland
[3]Department of Public Health, University of Helsinki, Helsinki, Finland
Contact: subas.neupane@tuni.fi

Background:

We examined the developmental trajectories of multisite musculoskeletal pain to acquire the developmental patterns of musculoskeletal pain among midlife municipal employees and whether pain trajectories associate with common mental disorders or behaviors.

Methods:

Middle-aged (44 to 67 years) municipal employees from the city of Helsinki were studied. The baseline survey was conducted in 2000-02 (N = 8960) and two follow-up surveys in 2007 (N = 7332) and 2012 (N = 6809). Repeated measurement of musculoskeletal pain in four anatomical sites was obtained. Trajectories of number of pain sites (0-4) were modeled using latent class growth analysis (n = 6527). Common mental disorders were measured using the General Health Questionnaire 12-item version (GHQ-12). Information on behavior factors, morbidity, and the socioeconomic position was obtained from the questionnaire survey. Associations of baseline factors with pain trajectories were assessed by multinomial logistic regression.

Results:

We found four distinct trajectories of the number of pain sites: high (15%), increasing (24%), decreasing (20%) and low (41%). In multivariable multinomial regression model high, increasing and decreasing trajectories were strongly associated with higher odds with both medium and high common mental disorders. However, the magnitude of the association was much higher for high vs. low trajectory group due to medium (OR 3.70, 95% CI 2.81-4.89) and high (OR 5.37, 95% 4.36-6.61) common mental disorders. Mean score of common mental disorders was also highest for high trajectory group. High, increasing and decreasing trajectory group were also associated with poor behavior, having one or more musculoskeletal comorbidities and low socioeconomic position.

Conclusions:

Multisite musculoskeletal pain remain persistent among midlife employees and those high trajectories of musculoskeletal pain are associated with common mental disorders, behavior, and musculoskeletal comorbidities.

Key messages:

- Four distinct trajectories of number of pain sites was identified among midlife municipal employees.
- High common mental disorders and poor behavior, as well as low socioeconomic position and musculoskeletal comorbidities were strongly associated with pain trajectories.

DL Health services research

Direct access physiotherapy for patients with musculoskeletal disorders: a systematic review

Aurelie Bourmaud

A Demont[1], *A Bourmaud*[1], *A Kechichian*[2], *F Desmeules*[3,4]
[1]INSERM 1123 ECEVE, Faculty of Medicine, University of Paris-Diderot, Paris, France
[2]University of Sorbonne, Pierre and Marie Curie, Paris, France
[3]Physiotherapy School, University of Montreal Affiliated Research Center, Montréal, Canada
[4]Maisonneuve-Rosemont Hospital Research Center, Montréal, Canada
Contact: aurelie.bourmaud@inserm.fr

Background:

Although the benefits of physiotherapy is well supported in the literature, the impact of having direct access to physiotherapy is not well established. Update of the current available evidence is warranted. The aim of this systematic review was to update the current evidence regarding the impact of direct access physiotherapy compared to usual care for patients with musculoskeletal disorders.

Methods:

Systematic searches were conducted in 5 bibliographic databases up until May 2018. Two independent raters reviewed studies and used the Quality Assessment Tool for Quantitative Studies to conduct the methodological quality assessment and a data extraction regarding patient outcomes, adverse events, health care utilization and processes, patient satisfaction and health care costs.

Results:

Sixteen studies of weak to moderate quality were included. Five studies found no significant differences in pain reduction between usual family physician led care and direct access physiotherapy. However, three studies reported better clinical outcomes in patients with direct access in terms of function and quality of life. Five studies did not observe any adverse events with direct access physiotherapy. Three studies showed shorter waiting time and four studies reported fewer number of physiotherapy visits with direct access. Three studies showed that patients with direct access were less likely to have medication and imaging tests prescribed compared to usual care. Five studies reported higher levels of satisfaction for direct access. In terms of health care costs, four studies demonstrated that costs were lower with direct access and one study reported similar costs between both types of care.

Conclusions:

Emerging evidence, although of weak to moderate quality, suggest that direct access physiotherapy provides equal or better outcomes than family physician led care models for musculoskeletal disorders patients. More methodologically strong studies are needed.

Key messages:

- This review supports the efficacy, safety and cost-effectiveness of direct access PT, while increasing access to care with a more efficient use of resources.
- There is a need for more methodologically strong studies to evaluate the efficiency of direct access models of care of physiotherapy for patients with MSKD.

Mapping, guiding, and assessing social prescription services in the UK

Kerryn Husk

K Husk[1]
[1]University of Plymouth, Plymouth, UK
Contact: kerryn.husk@plymouth.ac.uk

Background:

The use of non-health service referral, or 'social prescribing' interventions have been proposed as a cost-effective alternative to help those with long-term conditions manage their illness and improve health and well-being. We are generating theory through review and primary data collection relating to the social prescribing system, how to maximise the benefits of this system and how it might be implemented.

Methods:

A realist synthesis and evaluation. Working with three UK case-sites who are all at various stages in the process of setting up social prescription services, we are conducting patient pathway analyses, focus groups, and interviews. An important component of this work is iterative, targeted reviews of the literature relating to these pathways and identified mechanisms to assess effectiveness and reach.

Results:

The study is ongoing; however, we are testing prototype theory generated in a previous realist review (presented last year) and elaborating on which mechanisms within each pathway relate to suitable population types and aspects of wellbeing.

Conclusions:

We aim to draw together service delivery practitioners, users, researchers and clinicians to create specified theory for setting up social prescription services. This guidance will be context sensitive and make recommendations for increasing acceptability and spread of complex system service delivery and interventions.

Key messages:

- We are building highly specified, context sensitive system specification and 'lessons learned' implementation guidance for social prescribing programmes in the UK.
- We are producing these outputs through collaborative partnerships with services delivering programmes as they develop, using realist evaluation and qualitative comparative methods.

Developing a Patient Advocacy Scale for Nurses

Ezgi Sermet

E Sermet[1], *H Kadioglu*[1]
[1]Public Health Nursing, Marmara University Health Sciences Institute, Istanbul, Turkey
Contact: sermet.ezgi@gmail.com

Background:

Patients can sometimes become defenseless. Patient advocacy is one of the most important roles of nurses in healthcare. No valid and reliable instrument that evaluates nurses' behavior as patient advocates has been encountered in the literature. The purpose of this study was to develop a patient advocacy scale for nurses.

Methods:

This methodological study was conducted in Istanbul over the period October - December 2018 with 500 nurses. Initially, a scale of 57 items was devised after discussions with 14 academic and clinical nurses. The scale was tested for content validity using the Content Validity Index and for construct validity with Exploratory Factor Analysis, after which the scale's reliability was evaluated for item-total correlations using Pearson's correlation analysis and for internal consistency with Cronbach's Alpha.

Results:

Content validity index for the scale was found to be .97. The first factor analysis resulted in a 10-factor construct, where the eigenvalue for the scale was greater than 1 and the construct explained 63.43% of total variance. At the end of the factor analysis, items with factor loadings of less than .30 and those that appeared in more than one factor with differences of less than %10 were removed from the scale one by one and the analysis was repeated 18 times. In the last factor analysis of the 39-item scale, a 7-factor construct was found with an eigenvalue greater than 1 that explained 61.3% of total variance. The scale's item-total correlations ranged between .42 - .75 and Cronbach's coefficient alpha was calculated to be .95.

Conclusions:

The newly developed instrument was found to be valid and reliable. The scale can be used to assess the patient advocacy behavior of nurses working in Turkey. Its intercultural adaptation for use with nurses working in other countries is recommended.

Key messages:

- The Patient Advocacy Scale for Nurses has been found to be valid and reliable.
- It can be used to assess nurses' patient advocacy behavior.

Infrequent patient-physician conversations about sexual health at an Austrian university hospital

Nikola Komlenac

N Komlenac[1], *M Hochleitner*[1]
[1]Gender Medicine, Medical University of Innsbruck, Innsbruck, Austria
Contact: nikola.komlenac@i-med.ac.at

Background:

Many physical diseases are associated with sexual health problems. Studies concerning physicians' barriers to patient-physician conversations concerning sexual health often fail to go beyond descriptive analyses of such barriers. The current study focused on finding those barriers that best predict the frequency of patient-physician conversations concerning sexual health.

Methods:

An online-questionnaire assessed physicians' sociodemographic information, frequency of holding a discussion on sexual health issues with their patients, and self-perceived barriers to asking patients about sexual health issues. The study was conducted at an Austrian university hospital. 102 physicians (53.9% women/46.1% men) participated. Logistic regression models were calculated to analyze associations between physicians' barriers and the frequency of patient-physician conversations concerning sexual health in everyday practice.

Results:

Of the physicians, 61.8% reported having a discussion on sexual health with their patients at least rarely in their everyday clinical practice. Physicians' barriers that predicted low frequency of patient-physician conversations concerning sexual health were: expecting the patient to initiate such a conversation, not feeling responsible for this health issue, fear of offending the patient, and one's own shame and discomfort.

Conclusions:

In contrast to other studies about physicians' barriers to patient-physician conversations concerning sexual health, in the current study time constrains were not a prominent barrier to such conversations. Future training should help physicians recognize the relevance of sexual health in one's medical discipline and they should be taught how to overcome their feelings of shame or how to cope with patients' negative reactions during patient-physician conversations concerning sexual health.

Key messages:

- University hospital physicians rarely address sexual health issues in patient-physician conversations.
- Physicians most often handed the responsibility to initiate such conversations to the patient.

The risk of emergency department visits in adults living in rural France

G Mercier

G Mercier[1,2,3], Victor Rodwin[5], Catherine Quantin[4], Michael Chernew[3], Michael Gusmano[6]
[1]DIM, CHU de Montpellier, Montpellier, France
[2]CEPEL, UM/CNRS, Montpellier, France
[3]Health Care Policy Department, Harvard Medical School, Boston, USA
[4]DIM, CHU de Dijon, Dijon, France
[5]Wagner School of Public Service, New York University, New York, USA
[6]Institute for Health, Health Care Policy and Aging, Rutgers University, New Brunswick, USA
Contact: gregoire_mercier@hotmail.com

Background:

Individuals living in rural areas have poorer health outcomes due to complex causal pathways related to socio-economic status, health behaviors and lower use of primary care. Emergency department visits without inpatient admission (hereafter ED visits) are an indirect measure of access to primary care.

Objective:

To analyze the determinants of ED visits among French adults living in rural areas.

Methods:

We analyze survey data from the CONSTANCES cohort study, a representative sample of French adults aged 18-69 years. These data on individuals' demographics, self-reported and physician-reported clinical indicators, and individual socio-economic status, are linked to France's claims database (SNIIRAM). We analyze the risk of having at least one ED visit, in 2016, using a multivariate logistic regression model.

Results:

Among 12,834 adults included in the study, 1,412 (11%) had at least one ED visit in 2016. After adjustment, the ED visit risk was associated negatively with female gender (OR = 0.87; $p < 0.01$), age (OR = 0.97; $p < 0.01$), secondary education (OR = 0.85; p = 0.03), higher use of GPs (OR = 0.99; p = 0.02); and positively associated with the number of comorbidities (OR = 1.1; $p < 0.01$), poorer self-reported health status (OR = 1.01; p = 0.02), a higher self-reported depression score (OR = 1.01; p = 0.02), and acute care inpatient admissions (OR = 2.4; $p < 0.01$).

Conclusions:

These results suggest that, among adults living in rural France, those with a lower educational level are at higher risk of ED visits.

Policy implications: To reduce health disparities among rural and urban areas, policymakers and primary care professionals should focus on targeted outreach strategies to identify high-needs individuals.

Key messages:

- The risk of emergency department visit varies significantly among adult living in rural France.
- Among adults living in rural France, those with a lower educational level are at higher risk of ED visit.

Health benefits through prevention: there is still a lot to be gained

Paul Van Gils

PF Van Gils[1], AWM Suijkerbuijk[1], N van der Vliet[1], JJ Polder[1,2], A de Blaeij[1], GA de Wit[1,3], B Staatsen[1]
[1]RIVM, Bilthoven, Netherlands
[2]Tilburg University, Tilburg, Netherlands
[3]Utrecht University, Utrecht, Netherlands
Contact: paul.van.gils@rivm.nl

Introduction:

In November 2018, the Ministry of Health, Welfare and Sports presented the National Prevention Agreement (NPA). Within this NPA, interventions targeting smoking, being overweight and problematic alcohol use were proposed to induce lifestyle changes. In addition to measures aimed at these three themes, there is also a range of interventions that are promising, either because they could be cost saving or cost-effective, or because they have a positive impact on burden of disease. We explored which preventive interventions are promising in the Dutch context and systematically quantified costs, savings and health effects.

Methods:

In a literature search via the website kosteneffectviteitvanpreventie.nl we selected interventions that: a) have not yet been introduced in the Netherlands; and b) were promising with respect to effectiveness and cost-effectiveness. All interventions, including health protection and environmental measures, were eligible. We estimated the number of people who are eligible and compliant, costs and possible savings related to the interventions and health effects in terms of DALYs avoided. Interventions were ranked with regard to possible savings and DALYs avoided.

Results:

Our exploration shows a number of preventive interventions that are cost saving or cost-effective. These interventions are aimed at anxiety and depression, heart disease, skin cancer, fractures, air quality and road safety. Examples of cost-saving or cost-effective interventions are a food tax on food and drinks with high fat/sugar content, screening an aneurysm of the aorta and fully subsidized sound insulation of homes.

Conclusions:

Our study shows that there are much more preventive opportunities than those presented in the NPA. The substantiation of the interventions is often based on foreign research and findings therefore cannot be simply translated to the Netherlands. However, the interventions identified in this study are promising and deserve further consideration.

Key messages:

- Health gain by environmental measures.
- Many interventions are not systematically implemented.

Societal Expenditure on Prevention

Paul Van Gils

P Van Gils[1], AWM Suijkerbuijk[1], GA de Wit[1,2], JJ Polder[3,4], MA Koopmanschap[4,5]
[1]RIVM, Bilthoven, Netherlands

[2]Utrecht University, Utrecht, Netherlands
[3]Tilburg University, Tilburg, Netherlands
[4]RIVM, Bilthoven, Netherlands
[5]Erasmus University, Rotterdam, Netherlands
Contact: paul.van.gils@rivm.nl

Introduction:

In 2015, Dutch healthcare expenditure exceeded 85 billion euros. But what about prevention? In this study we estimated national expenditure on prevention. A distinction was made between health protection, health promotion and disease prevention. In the estimation of prevention expenditures, this study is limited to universal, selective and indicated prevention, as healthcare-related prevention can hardly be distinguished from curative care. This study analyzed expenditure on preventive activities in the Netherlands in 2015 and took a societal perspective.

Methods:

We used various sources to investigate spending on prevention in 2015. Insofar as costs were part of healthcare expenditure, estimates were based on the Care Accounts of Statistics Netherlands. For the remainder, we estimated expenditure using annual reports and annual accounts of governments and other organizations. We included preventive activities by consumers, industry, NGOs, insurance companies, and government.

Results:

In 2015, an estimated € 12.4 billion (1.8% of the GDP) was spent on prevention: € 2.4 billion on disease prevention (19%), € 0.6 billion on health promotion (5%) and € 9.4 billion on health protection (76%). This is a decrease of 17% compared to 2007, the last year that a similar estimate was made. Within health promotion, the largest expenditure was for working conditions and safety: € 160 million. € 67 million was spent on mental disorders. The largest expenditure item within disease prevention was dental care: € 675 million. Within health protection, this was the sewer by more than € 3 billion.

Conclusions:

Spending on prevention is relatively low compared to total spending on healthcare. The largest part is targeted at health protection. In the coming years there may be an increase in expenditure, due to more governmental prevention policies such as the National Prevention Agreement.

Key messages:

- Spending on prevention is relatively low compared to total spending on healthcare.
- Relatively little money for health protection.

Used and foregone of primary care in French university students

Marie-Pierre Tavolacci

M Tavolacci[1,2], *P Habihirwe*[1], *P Déchelotte*[2], *J Ladner*[2,3]
[1]CIC 1404, Rouen University Hospital, Rouen, France
[2]INSERM 1073, Rouen Normandy University, Rouen, France
[3]Department of Epidemiology and Public Health, Rouen University Hospital, Rouen, France
Contact: Marie-Pierre.Tavolacci@chu-rouen.fr

Background:

University students tend to find it difficult to ask for help especially when it comes to health issues. The objective of the study was to determine the health issues of general practitioner and the reasons of primary care foregone in university students.

Methods:

A cross sectional study was conducted in 2018 in Normandy university students (France). The socio demographic characteristics of the university students were collected. The primary care seeking during the previous 12 months were assessed by the consultation to the general practitioner and categorized: acute physical issues (stomach aches, cough ...), chronic physical issues (asthma, diabetes...), mental health issues (stress, anxiety...) and preventive medicine (vaccine, certificate...). The foregone of primary care during the previous 12 months and the barriers to accessing primary health-care-seeking were also collected.

Results:

1179 university students (58.0% of women, age mean 20.4 years) were included. Frequency of health issues in the last 12 months were preventive issues (57.2%), acute physical issues (52.2%), chronic physical issues (16.7%) and psychological issues (18.4%). The foregone of primary care of the university students was reported by 20.5% of university students. The three main barriers reported by these students to accessing primary health-care-seeking behaviour were self-treatment (60.6%), lake of time (64.7%) and financial barriers (25.4%). Logistic regression showed that the foregone of primary care was positively associated with being female students AOR = 1.69 CI95% (1.21-2.36), grant holder AOR = 1.52 CI95% (1.10-2.02), and living in rented accommodation AOR = 1.47 CI95% (1.03-2.02).

Conclusions:

Half of university students consult the general practitioner for physical concerns and one fifth for psychological disorders. However with 20% of primary care foregone by university students, the access of primary care in the targeted population could be improved.

Key messages:

- One fifth of university students foregoes to primary care.
- Female students, grant holder and living in accommodation are the risk factors of foregone of primary care.

Evaluation designs of outpatient health centres focusing on vulnerable patient groups

Roman Winkler

R Winkler[1], *I Reinsperger*[1]
[1]Ludwig Boltzmann Institute for Health Technology Assessment, Ludwig Boltzmann Gesellschaft, Vienna, Austria
Contact: roman.winkler@hta.lbg.ac.at

Background:

Homeless and non-insured persons experience worse physical and mental health than comparable populations. Outpatient (public) health institutions, which are easily accessible, contribute considerably to the medical treatment of vulnerable patient groups. Sound evaluation methods, indicators and instruments are necessitated to target patients' needs and to enable strategic health and social policy planning.

Methods:

We conducted a systematic literature search in several databases (PubMed, EMBASE, PsycINFO etc.) for studies from 2000 to 2019 reporting on evaluations in outpatient health institutions for homeless and/ or non-insured patients. In addition, we contacted 5 Austrian public health/ research institutions dealing with complex interventions for relevant publications.

Results:

12 evaluation studies and 7 evaluation reports met our inclusion criteria. Evaluation designs mostly considered various target groups and nearly all assessments pursued a 'mixed-method' approach. 13 publications assessed socio-demographic data, 11 the use of health and social services and 7 patients' health status. Further indicators related to 'satisfaction issues' such as patients' satisfaction with the provided range of health and social services (n = 7). 6 publications reported on health economic indicators. In total, 7 out of 19 studies reported on evaluation instruments; most instruments (n = 6) were on patients' mental health status.

Conclusions:

Patients represented the major target group in the included evaluations. There is little research on evaluation indicators directing on health professionals. Evaluations focusing on the intersectional levels (e.g. the impact of health programmes for vulnerable groups on various institutions) are lacking.

Key messages:

- Evaluation designs involving 'hardly to reach populations' shall consider a 'participatory assessment approach' to avoid drop-outs and to create a trustworthy evaluation situation.
- Hence, evaluation indicators shall be commonly selected and adequately reflect patients' realities.

Healthcare providers' perceptions of difficulties related to frequent users of emergency departments

Véronique S Grazioli

V Grazioli[1,2], M Kasztura[1], O Chastonay[1], M Graells[1], E Schmutz[1], M von Allmen[1], M Lemoine[1], J-B Daeppen[2], O Hugli[3], P Bodenmann[1]
[1]Center for General Medicine and Public Health, Department of Vulnerabilities and Social Medicine, Lausanne, Switzerland
[2]Addiction Medicine, Department of Psychiatry, Lausanne, Switzerland
[3]Emergency Department, Lausanne University Hospital, Lausanne, Switzerland
Contact: veronique.grazioli@chuv.ch

Background:

Frequent users of emergency department (FUEDs; ≥ 5 ED visits/ year) are often vulnerable individuals cumulating medical, social and substance use problems. FUEDs often require complex and sustained care coordination generally unavailable in ED and are commonly considered contributing to ED crowding. In view of supporting ED health-care providers through specific training and interventions tailored to FUEDs, this study aimed to explore ED healthcare providers' perceptions of difficulties related to FUEDs.

Methods:

Participants (N = 208) were ED healthcare providers (i.e., nurses, physicians) from 75 university and community hospitals in Switzerland (71% of all EDs) who answered a questionnaire on FUEDs. They were asked to indicate the extent to which FUEDs represent a problem in their ED. Perceived difficulties related to FUEDs were elicited by an open-ended question. Conventional content analysis was used to extract common categories and themes.

Results:

Among the 208 participants, 134 (64%) reported that FUEDs represent a problem. Of those, 132 provided 1 to 5 answers to the open-ended question. Twenty-eight categories were identified and organized in 4 themes. First, participants reported difficulties related to FUEDs' characteristics themselves (e.g., problem's chronicity; behavioural difficulties) leading to healthcare complexity. Second, participants perceived negative consequences related to the presence of FUEDs in the ED (e.g., work overload, staff helplessness and fatigue). Third, ED healthcare offer was considered inappropriate and inefficient to respond to FUEDs needs and fourth collaborating with FUEDs' existing healthcare network was perceived as difficult.

Conclusions:

ED healthcare providers experience a wide range of difficulties related to the management of FUEDs. Providing training and implementing a case management intervention tailored to FUEDs might support ED health-care providers and contribute to address FUEDs' complex needs.

Key messages:

- ED healthcare providers perceive FUEDs to represent a problem.
- Perceived difficulties might decrease through training and case management support might contribute to better address FUEDs complex needs.

Is there an association between social determinants and care dependency risk?

Susanne Schnitzer

A Schneider[3], S Blüher[1], U Grittner[3], V Anton[1], E Schaeffner[2], N Ebert[2], P Martus[4], A Kuhlmey[1], S Schnitzer[1]
[1]Institute of Medical Sociology and Rehabilitation Science, Charité - Universitätsmedizin, Berlin, Germany
[2]Institute of Public Health, Charité - Universitätsmedizin, Berlin, Germany
[3]Institute of Biometry and Clinical Epidemiology, Charité - Universitätsmedizin, Berlin, Germany
[4]Institute of Clinical Epidemiology and Biometry, Universitätsklinikum Tübingen, Tübingen, Germany
Contact: susanne.schnitzer@charite.de

Background:

Despite a growing body of knowledge about the morbidities and functional impairment which frequently lead to care dependency, the role of social determinants is not yet well understood. The purpose of this study was 1) to examine the effect of social determinants on care dependency onset and progression, and 2) to analyse the effect of social determinants on various levels of care dependency.

Methods:

We used data from the Berlin Initiative Study (BIS), a prospective, longitudinal, population-based cohort study including 2069 older participants (≥70 years of age) with visits in 2009, 2011 and 2013. Care dependency was assessed if participants require substantial assistance in at least two activities of daily living for 90 minutes daily (level 1) or three hours+ daily (level 2). Social determinants were defined as partnership status, education, income, age and gender. Data were analysed with multi-state time to event regression modeling which simultaneously model several competing events, as well as not only first but also second or third event in one model.

Results:

During the study period, 556 participants (27.5%) changed their status of care dependency. Persons who reported having no partner at baseline were care-dependent more often than participants with a partner (43.7% 'no partner' / 27.1% 'with partner'). In the multiple model having no partner compared to having a partner was associated with a higher risk of transition from no care dependency to level 1 (HR: 1.25, 95%CI: 0.97-1.64), however failed significance. The significant association between care dependency and income and between care dependency and education ceased as well after adjustment for co-morbidities.

Conclusions:

Results indicate that older people without a partner tend to be on a higher risk of care dependency onset but not on a higher risk of care dependency progression. Inequality between education and income groups can be explained in terms of morbidity.

Key messages:

- The significant association between care dependency and income and between care dependency and education can be explained in terms of morbidity.
- Results indicate that older people without a partner tend to be on a higher risk of care dependency onset but not on a higher risk of care dependency progression.

Hospitalization patterns of uninsured as base for services and health need assessment

Silvia Florescu

M Ciutan[1], S Florescu[1], M Dosius[1], SG Scîntee[1], C Vlădescu[1]
[1]National School of Public Health, Management and Professional Devolopment, Bucharest, Romania
Contact: florescu.silvia@gmail.com

Background:

Solidarity is crucial for shifting from centralized to social health insurance model. Uninsured receive at least emergency and basic services free-of-charge. To which extent this policy really covers their health and services needs remains to be assessed.

Methods:

DRGNational database (457 hospitals) was interrogated for continuous hospitalization of uninsured, 2014-2018. Use patterns were identified by episodes, LOS, diagnose, admission criterion. Avoidable admissions were assessed according to OECD criteria.

Results:

Number of hospital episodes in uninsured varied annually, difference ranging from -13.5 to 6.3%; largest decrease in 2015 possibly due to day surgery implemented in 2014. About 2.5-3% of all episodes and hospitalization days were for uninsured. Use patterns identified: Most common admission criterion: Emergencies (95%) compared to Specific diagnosis&treatment, Births, Potentially endemic/epidemic diseases; Most frequent diagnosis: Emergency around birth,Mental disorders, Respiratory infections; Men 45 years old living in rural areas prevailed significantly; significant gender difference by age (9 years; t-test, $p < 0.05$); 3% of hospitalizations could be avoided by assistance in prehospital (asthma, COPD, CHF, Diabetes&utation).

Conclusions:

The use patterns identified show inequity in access and gaps in policy meant to ensure solidarity in health. Day surgery was inittially beneficial in reducing financial burden, but addressing to prehospital health services continues to be low inducing overload of emergency units. A solution could be higher involvement of other sectors to ensure socio-economic security for all. Free-of-charge emergency hospital services ensure access for life threatening conditions but shortcut pre-hospital and postpone initial visits until non-preventable/-manageable stages.

Key messages:

- Reconsider services package to increase access for uninsured. Develop bridges between domains able to meet health related needs by intersectorial collaborations: labor, social, economic, health etc.
- Periodic analyze hospitalizations of uninsured, together with legal framework and sectoral policies to allow an appropriate decisions making and tailored intervention design.

The experience of patients and family caregivers during Hospital-at-Home in France

Helene Rossinot

H Rossinot[1], *O Marquestaut*[1], *M De Stampa*[1]
[1]HAD, AP-HP, Paris, France
Contact: helene.rossinot@yahoo.fr

Background:

Public health policies tend to generalize the use of Hospital-At-Home (HAH) to answer the growing will of patients to be treated or to die at home. HAH is a model of care that provides acute-level services in the patient's home with the interventions of variety of health care professionals. Relatives participate also in the interventions by helping for sick patients at home, but we lack data on the care of patients and caregivers in HAH. The aim of this study was to make an inventory of the experiences of patients and family caregivers in HAH.

Methods:

The research was qualitative using nineteen semi-directed interviews from nine patients and ten caregivers of one care unit of Greater Paris University Hospitals' HAH, and the grounded theory was used to analyze the transcripts. Caregivers were also asked, after the interview, to fill in the Zarit Burden Inventory.

Results:

HAH remained mostly unknown for patients and caregivers before the admission proposition and the outlook of being admitted in HAH was perceived as positive, for both of them. Caregivers had a versatile role throughout HAH, leading to situations of suffering, but also had sources of support. The return home was considered satisfactory by both caregivers and patients, related to the quality of care and increased morale despite HAH's organizational constraints. We noted an impact of HAH on the relationship between the patient and the caregiver(s), but caused by multiple factors: the fact that the care takes places at home, its consequences but also the disease itself.

Conclusions:

HAH strongly involved the patient's caregiver(s) all along the process. HAH's development necessitates to associate both patients and caregivers and to take into account their needs at every step. This study highlights the need to better assess the ability of the caregiver to cope with his or her relative in HAH with acute and subacute care at home.

Key messages:

- Health care services need to take into account family caregivers.
- Hospital at home services should be developped worldwide.

Effectiveness of participatory interventions in improving clinical coordination in Latin America

M Luisa Vázquez Navarrete

A Miranda Mendizabal[1], *I Vargas*[1], *I Samico*[2], *P Eguiguren*[3], *AS Mogollón-Pérez*[4], *J López*[5], *F Bertolotto*[6], *ML Vázquez, for Equity LA II*[1]
[1]Health Policy and Health Services Research Group, Consortium for Health Care and Social Services of Catalonia, Barcelona, Spain
[2]Group of Studies on Management and Evaluation in Health, Integral Medicine Institute ''Prof. Fernando Figueira'', Recife, Brazil
[3]School of Public Health ''Dr. Salvador Allende Gossens'', University of Chile, Santiago de Chile, Chile
[4]Faculty of Medicine and Health Sciences, Rosario University, Bogota, Colombia
[5]Public Health Institute, Veracruzana University, Veracruz, Mexico
[6]Faculty of Nursing, University of the Republic, Montevideo, Uruguay
Contact: mlvazquez@consorci.org

Background:

Evaluation of interventions to improve clinical coordination across care levels is scarce in Latin America.

Aim:

to evaluate the effectiveness of interventions implemented through participatory action research in improving clinical coordination between care levels in public healthcare networks of Brazil, Chile, Colombia, Mexico and Uruguay.

Methods:

Quasi-experimental study (controlled before and after design). Comparable networks, one intervention (IN) and one control (CN), were selected in each country. Baseline (2015) and evaluation (2017) surveys were conducted applying COORDENA® questionnaire to a sample of primary (PC) and secondary (SC) care doctors (174 doctors/network/year). Designed interventions promoted clinical agreement and communication across levels for patients' follow-up. Outcome variables: a) intermediate: interactional and organizational factors; b) final: experience of clinical management coordination (care consistency and patients' follow-up) and general perception of coordination between levels. Poisson regression models were estimated.

Results:

Intermediate: interactional factors -personal knowledge and trust on the other care level-increased significantly in Brazil' and Chile' INs; and organizational factors -managers' support- in the INs of Colombia and Mexico. Comparing to CN in 2017, INs of Brazil, Chile, Colombia and Mexico showed significant differences in some factors.

Final: care consistency items -agreement over the treatments- improved in the INs of Brazil, Colombia and Uruguay; and patients' follow-up in the INs of Chile and Mexico. General perception of clinical coordination increased in the INs of Brazil, Colombia and Mexico. Compared to CN in 2017, only Brazil showed significant differences.

Conclusions:

Improvements in intermediate and final care coordination results, consistent with expected results, were observed in all the INs. Reduced implementation time and some process and context factors may have limited their impact.

Key messages:

- First study assessing the effectiveness of participatory interventions in improving clinical coordination between care levels in public healthcare networks of Latin America.
- Results showed changes in the intermediate and final clinical coordination results in the intervention networks. Longer implementation and evaluation times are expected to achieve greater impact.

Associated factors to the perception of clinical coordination in the Catalan national health system

M Luisa Vázquez Navarrete

L Esteve Matalí[1], I Vargas[1], E Sánchez[2], F Cots[3], P Plaja[4], À Avecilla[5], I Ramon[6], E Medarde[7], L Colomés[8], ML Vázquez for GAIA[1]
[1]Consortium for Health Care and Social Services of Catalonia, Barcelona, Spain
[2]Serveis de Salut Integrats del Baix Empordà, Palamós, Spain
[3]Parc de Salut Mar, Barcelona, Spain
[4]Fundació Salut Empordà, Figueras, Spain
[5]Badalona Serveis Assistencials, Badalona, Spain
[6]Consorci Hospitalari de Vic, Vic, Spain
[7]Consorci Sanitari de Terrassa, Terrassa, Spain
[8]Grup SAGESSA, Reus, Spain
Contact: mlvazquez@consorci.org

Background:

Clinical coordination across levels of care is a priority for health systems. The aim is to analyse the factors associated to a high perception of clinical coordination of primary (PC) and secondary care (SC) doctors of the Catalan national health system (NHS).

Methods:

Cross-sectional study based on the self-administered online questionnaire COORDENA-CAT. Data collection: October-December 2017. Study population: PC and SC (acute and long term) doctors of the public Catalan NHS that had been working for at least one year in the organization, had direct contact with patients and related with doctors of the other level of care. The participation rate was 20.5%, with a sample of 3308 doctors. Outcome variable: perception of clinical coordination across levels of care. Explanatory variables: socio-demographic, employment characteristics, attitude towards work, type of area (according to type of hospital and managing entity), interactional factors, organizational factors and knowledge of existing coordination mechanisms. Stratification variable: level of care. Descriptive and multivariate analysis by logistic regression.

Results:

Only 32.13% of PC doctors and 35.72% of SC doctors found that patient care was coordinated across care levels within their area. In both levels of care, knowing the doctor of the other level; finding that their practice influences the other care level; finding that the organization's management facilitates coordination; working in an area where the same entity manages SC and majority of PC and to hold joint clinical case conferences are factors positively associated to a high perception of clinical coordination. Besides, there are other positively associated factors exclusive for each level of care.

Conclusions:

Several common interactional and organizational factors are positively associated to a high perception of care coordination. Introducing policies to enhance such factors can foster care coordination in the Catalan NHS.

Key messages:

- This study found out factors associated to clinical coordination across care levels in each level.
- It helps to develop specific coordination policies by level of care to address those factors.

Geographical accessibility to permanent care centers of family doctors from Bihor County, Romania

Dorel Petru Tirt

DP Tirt[1,2,3], D Rahota[2,3]
[1]Romanian Association for Public Health, Bucharest, Romania
[2]Faculty of Medicine and Pharmacy, University of Oradea, Oradea, Romania
[3]Public Health Directorate of Bihor County, Oradea, Romania
Contact: doreltirt@yahoo.com

Accessibility (geographic or spatial) to health services is a component of health care services access that through measurement can assess inequities in health. Geographical accessibility can be measured using a geographic information system (GIS) where travel time is calculated from the patient's home to the place where a service is delivered. Permanent care centers of family doctors (PCCs) are units providing family medicine services (consultations, injections, solving minor emergencies) outside the work schedule of family doctors (night and holiday), for overloading prevention of emergency hospitals services by direct addressing or by calling to the unique emergency number 112. Bihor County has 617118 inhabitants in the 101 administrative-territorial units (458 localities), 334 family medicine practices, and there were 34 PCCs.

We intended to identify the number of localities in more than 10, 20 or 30 minutes of travel by car from the PCC (based on end-2018 data). A GIS was created using the QGIS application, which includes layers: the county border, the 454 localities and the georeferenced addresses of PCC. Using the ORS Tools plug-in, the appropriate isochrones were created. Then overlapping isochrones and localities (points), the number of localities for which the travel time to the nearest PCC is greater than 10, 20 and 30 minutes, respectively, was obtained.

The time needed for the inhabitants to reach the PCC is: more than 10 minutes for 247 localities; more than 20 minutes for 81 localities and over 30 minutes for 10 localities. The results are presented in the form of maps and in tabular form (localities). Using GIS, accessibility to medical services in a territory (city, county, country) can be measured. The application of free GIS software, QGIS, requires hardware, staff training, procedures (for work and decision-making) to research and improve population access to health services.

Key messages:

- Access to health services can be assessed using geographic information systems.
- The use of appropriate maps facilitates decision making to optimize health services.

Healthcare Use in Multimorbidity Patients

Guilherme Quinaz Romana

G Quinaz Romana[1,2], I Kislaya[2,3], S Cunha Goncalves[4,2], MR Salvador[5,2], B Nunes[2,3], C Matias Dias[2,3]

[4]Public Health Unit, ACES Medio Tejo, Lisbon, Portugal
[5]Public Health Unit, ACES Dao Lafoes, Viseu, Portugal
Contact: gquinaz.romana@gmail.com

Background:

The existence of multiple chronic conditions in the same patient is a public health problem, recognized as relevant to health systems. Individuals with multimorbidity have additional health needs, which in the context of continuous increase of life expectancy, imply a heavy burden to healthcare services.

Methods:

We analysed the association between healthcare use (primary care, medical specialist consultations and hospitalizations) and multimorbidity in the Portuguese population aged 25-74 years old, using the Health Examination Survey (n = 4911) data. Logistic regression models adjusted for predisposing (age, education) and enabling (income, region of residence) factors were fitted separately for male and female. Odds ratios and CI95% were estimated.

Results:

Prevalence of multimorbidity was 38.3% (95%CI: 35.4%; 41.3%). In males, after adjustment for confounding and when compared to patients without chronic conditions, multimorbidity was associated with greater use of primary care (OR = 3.7; CI95%: 2.3-5.8), medical specialist consultations (OR = 1.9; CI95%: 1.1-3.4) and hospitalizations (OR = 1.8; CI95%: 1.2-2.7). In female, statistically significant association between multimorbidity and healthcare use was observed for primary care (OR = 2.6; CI95%: 1.6-4.3) and medical specialist consultations (OR = 2.8; CI95%: 2.0-3.9), but not for hospitalizations. Both male and female with multimorbidity reported greater use of primary care, compared to individuals with only one chronic condition (OR = 2.4; CI95%: 1.3-4.4 and OR = 1.7; CI95%: 1.1-2.8, respectively).

Conclusions:

Our results show a greater healthcare use in patients with multimorbidity, both in primary and hospital care. The availability of scientific evidence regarding the healthcare use, by patients with multimorbidity, may substantiate the discussion about the possible need for the Portuguese health system to adapt to these patients, with changes in policies that will allow better and more efficient treatment.

Key messages:

- This study may support the discussion about the adaptation of Portuguese health system to patitents with multimorbidity.
- Further discussion on policy change is needed, targeting an efficient management of these patients.

Hospital volume and five-year survival after cancer surgery in 2007-2011 in Osaka, Japan

Sumiyo Okawa

S Okawa[1], *T Tabuchi*[1], *T Morishima*[1], *S Koyama*[1], *Y Taniyama*[2], *I Miyashiro*[1]
[1]Cancer Control Center, Osaka International Cancer Institute, Osaka, Japan
[2]Graduate School of Medicine, Osaka University, Osaka, Japan
Contact: sumiyo.okawa@gmail.com

Background:

The relationship between hospital volume (HV) and patient outcome is well-known evidence, and hospital volume is widely used as a quality indicator. In Japan, however, few studies are available on the associations between HV and survival after cancer surgery. This study aimed at examining the association between HV and longitudinal survival after surgeries of major cancer sites.

Methods:

This is a retrospective observational study. Using the Osaka Cancer Registry database, we identified patients who were diagnosed as major sites of cancer (esophageal, gastric, colorectal, pancreatic, lung, breast, and uterus cancer) between 2007 and 2011, and undergone surgeries in Osaka. To define the quartiles of HV (high, medium, low, and very low-volume hospitals), we ranked hospitals by annual surgical volume, sorted patients in descending order of HV, and assigned them into four equal-sized groups. The study outcome was five-year survival from the diagnosis. We analyzed the associations between hospital volume and survival among eligible patients aged between 15 and 84 years old, using Cox proportional hazard models. In the models, we adjusted for characteristics of patient and treatment received by the patients.

Results:

A sample of 86,867 patients were analyzed. The mortality hazards of patients treated at very low-volume hospitals were 1.4 - 2.1 times higher than that of patients treated at high-volume hospital in all selected cancers. However, absolute differences (percent points) in adjusted survival rates between high- and very low-volume hospitals were varied by cancer site: esophagus (24.2), stomach (14.9), colorectum (11.5), pancreas (9.2), lung (10.8), breast (2.4), and uterus (3.3).

Conclusions:

Very low-volume hospitals showed the poorest patient survival after cancer resections. Healthcare quality assessment at lower-volume hospitals and referrals to higher-volume hospitals are potential measures to improve survival of cancer patients.

Key messages:

- Patients treated at lower-volume hospitals had a higher mortality risk than those treated at higher-volume hospitals.
- Healthcare quality assessments and effective referrals of high-risk patients are potential interventions to improve patient survival.

Research Management Committee as strategic device for Implementation Research

Carlos Alberto dos Santos Treichel

CAS Treichel[1], *MC Silva*[1], *RF Presotto*[1], *RT Onocko-Campos*[1]
[1]Department of Collective Health, University of Campinas, Campinas, Brazil
Contact: carlos-treichel@hotmail.com

Issue/problem:

Implementation Research (IR) are particularly useful in identifying whether when an intervention does not succeed, this is because the intervention was ineffective in the new scenario or if a good intervention was poorly implemented. In order to do this, it is important to establish evaluation strategies capable of provide feedback and encourage learning and incorporation of changes. However, the best strategies for this are not clear yet.

Description of the problem:

Despite the existence of references with clear definitions of the outcomes for IR, it is still unclear what are the best strategies for the stakeholders' participation in these outcomes evaluation. By identifying that, the framework of participatory research could contribute to the choice of these strategies. We sought to retrieve some of the devices already used in other research to test whether they would be able to respond to the assumptions of IR. The chosen device was the Research Management Committee (RMC) which has its use evaluated by a qualitative study with focus group and the data review of the minutes of meetings held by the RMC.

Results:

The RMC functioned as a space where members of the research team, managers and workers from the services where the intervention occurred could meet systematically to plan, monitor and make adaptations in the IR. Besides its success as a tool for accessing outcomes, the RMC has also proved to be an important strategy to promote the increasing of acceptability, adoption, penetration and sustainability.

Lessons:

The RMC was an important promoter of the participation for the stakeholders in several aspects of the research; made possible the evaluation and monitoring of the meaning and feasibility of the research in the field of study from the point of view of those who live the experience of daily work and care; and favored access to the outcomes of IR in a transversal and organic way.

Key messages:

- The RMC is a strategic device for Implementation Research and configures a possibility to make the research a more dialogic and potentially transformative process.
- Besides its success as a tool for accessing outcomes, the RMC has also proved to be an important strategy to promote the increasing of acceptability, adoption, penetration and sustainability.

Improving inmates in Norwegian prisons' oral health

Kjersti Evensen

K Evensen[1], *L Næss*[1]
[1]R&D, Competence Centre at the Regional Odonatological Centre of Expertise, Stavanger, Norway
Contact: kjersti.berge.evensen@throg.no

Background:

Inmates in Norwegian prisons have poorer dental health than the general population. Inmates are a vulnerable group, often not able to take advantage of the dental health services or able to take care of own oral health. Poor dental health may have an impact on general health, in that people with poor oral health often suffer from pain and impairment and often feel restricted in activities at school, work or home. Oral health is declared as a human right by the World Dental Federation, and has gained recognition through the World Health Organization who emphasize on strengthening public dental health programs. The aim of this study was to explore the effect of an intervention based on Motivational Interviewing (MI) on improved dental health across inmates in Norwegian prisons.

Methods:

Inmates in Norwegian prisons were offered an oral examination and a small package containing toothbrush, toothpaste and floss- in addition to a short MI-intervention (20 minutes) by a dental hygienist. The participants were interviewed appr. 2 weeks later by a researcher to assess the effect of the intervention. The qualitative data-analyses were guided by thematic analysis.

Results:

The findings indicate that the intervention had a positive effect on behavioural change and motivation related to dental health care. The findings indicate that the intervention improved the inmates daily dental health care through better routines and motivation.

Conclusions:

The findings suggest that the intervention has a positive impact on inmates' oral health. The inmates changed routines related to daily dental care and reported higher motivation for taking care of their oral health. This is one of the first studies that explores the effect of an intervention to improve inmates' oral health and bridges a knowledge-gap in the literature. The findings may increase the understanding of how dental services should be organized and offered to provide dental health care for this vulnerable group.

Key messages:

- Poor oral health is associated with poor general health, and inmates in Norwegian prisons have poorer dental health than the general population.
- The aim of this study was to explore the effect of Motivational Interviewing on improved dental health across inmates. Findings: positive effect on the motivation and behavior related to oral health.

Improving diabetes care through educational intervention in primary care in rural China

Shaofan Chen

S Chen[1,2], B Burstrom[3,4], K Burstrom[1,4], D Qian[2,4]
[1]Department of Learning, Informatics, Management and Ethics, Karolinska Institutet, Stockholm, Sweden
[2]School of Health Policy and Management, Nanjing Medical University, Nanjing, China
[3]Department of Public Health Sciences, Department of Public Health Sciences, Stockholm, Sweden
[4]Center for Health Policy Studies, Nanjing, China
Contact: shaofan.chen@ki.se

Background:

The burden type 2 diabetes mellitus (T2DM) is increasing in China, especially in rural areas. The New Round of Health Care Reform in China intended to strengthen primary care, and promote the vertical integration between hospital care and primary care, in order to respond to the threat of T2DM. This study aimed to assess the impact of an educational intervention to improve vertical integration and management of T2DM in primary care in rural China, on glycemic control and diabetes knowledge.

Methods:

The educational intervention was conducted in cooperation between the county level hospitals and primary care in rural areas (including township health centres and village clinics). T2DM patients in three counties in Jiangsu Province were randomly divided into an intervention group, which received an education-based intervention and follow-up visits, and a control group which received standard care. Questionnaire interviews and medical records were used to collect patient data, including fasting blood glucose (FBG) level and diabetes knowledge, at baseline and follow-up, in 2015 and 2016, respectively. Difference-in difference analysis and Mann-Whitney U test were used.

Results:

The FBG level decreased significantly and diabetes knowledge increased significantly in the intervention group compared to the control group. The FBG level and diabetes knowledge score improved significantly in the intervention group in all counties, but there were local variations in levels.

Conclusions:

The increased integration between the county level hospital and primary care service with an educational intervention among T2DM patients had a positive impact on the FBG level and diabetes knowledge score in the intervention group compared to the control group after one year. The results are suggesting that the care of diabetes in rural China may be improved through more intense collaboration between hospital care and primary care.

Key messages:

- The increased integration had a positive impact on the glycemic control and diabetes knowledge among T2DM patients.
- Diabetes care in rural China may be improved through increased collaboration between hospital care and primary care.

Implementing treatment guidelines for ambulance services in a low- and middle income setting

Henrik Carlsson

H Carlsson[1], V Blaku[2], H Lidberg[1], R Hodza-Beganovic[1,3], P Berggren[1,4]
[1]International Medical Program, Centre for Teaching and Research in Disaster Medicine, Linköping, Sweden
[2]Qendra e Mjekesise Urgjente, Qendra e Mjekesise Urgjente, Pristine, Kosovo
[3]School of Health Science, Örebro University, Örebro, Sweden
[4]Linköping University, Linköping University, Linköping, Sweden
Contact: Henrik.C.Carlsson@regionostergotland.se

Background:

The use of clinical practice guidelines in clinical and organizational decision-making improves the care of patients and patient safety. Guidelines make healthcare consistent and efficient. In many low- and middle income countries healthcare workers depend on guidelines developed in higher income countries. For these to be useful and accepted they need to be adapted to the local setting. The aim of the study was to implement pre-hospital treatment guidelines into an organization that was not currently using guidelines. The study was partnership between a Swedish pre-hospital training organization and local ambulance service organizations in Kosovo.

Methods:

An iterative process of implementing the guidelines was used:

- Identify guidelines appropriate for the local organization.
- In sets of five, have the guidelines translated into Albanian.
- Adapt the guidelines to the local conditions and context.
- Approval of guidelines by an expert group.
- Begin using the guidelines within the target organization.

Results:

The first set of five guidelines was translated, approved, and implemented into the organizations. To improve acceptance, both practitioners and decision-makers were involved in the process. Seven workshops were held, with a total of 104 participants. In follow-up discussions participants said they accepted the guidelines and that they would be useful in their daily work.

Conclusions:

It is important to evaluate to what extent the guidelines have been accepted, understood, and used. The success and acceptance is due to the flexible procedure managing the full implementation process. Adapting guidelines to fit with local needs and requirements using local experts made the guidelines accessible and useful. The workshop discussions established justification and approval.

Key messages:

- Involve local experts in contextualising guidelines to increase acceptance from the start.
- Support building a robust local implementation organization to assist and administer change.

Two-year supervised tooth brushing program evaluation in preschools in Southern Israel

Dan Dekel

D Dekel[1], *S P Zusman*[2], *V Pikovsky*[3], *L Natapov*[2]
[1]Regional Health Office, Ministry of Health, Beer Sheva, Israel
[2]Dental Health Division, Ministry of Health, Jerusalem, Israel
[3]Regional Health Office, Ministry of Health, Ashkelon, Israel
Contact: dandekel@gmail.com

Background:

Dental care for children was included into National Health Insurance Law in 2010 and eligibility age went up gradually to 18 in 2019, providing universal dental care. As a part of dental care reform, community based preventive School Dental Services were extended to preschool children. School dental service (SDS), funded entirely by the State, was extended to younger ages providing supervised tooth brushing module. The national supervised teeth brushing program (STBP) was first implemented in 2015-2016 amongst 3-4 year old children attending 600 nurseries in Israel. Due to the program's success, it was gradually extended to more nurseries in low socio economic regions across the country, reaching 2200 settings in 2019.

The objective of this study was to assess dental health among preschool children participating in the program during the last two years, comparing to those who did not.

Methods:

Participant and non-participant kindergartens were randomly selected in Jewish and Bedouin Arab towns in the Southern district matched according to SES level. DMFT index measuring mean number of decayed, missing and filled teeth was recorded among preschool 5 years-old children.

Results:

283 children were examined, 157of them Jewish (86 participants in STBP, 71 non-participants) and 126 Bedouins (59 vs 67 respectively). Mean untreated carious teeth (d) was 1.15 vs 1.8 for Jews and 3.22 vs 3.9 for Bedouins. Percent of treated teeth within total caries experience index (f/dmf) was higher in tooth brushing group: 37% vs. 29% for Jews and 23% vs. 8% for Bedouins.

Key messages:

- Supervised tooth brushing shows favorable effect.
- Less carious teeth and more treated caries were recorded in STBP group.

Public Health Nurse and interprofessional collaboration related to adolescent mental health problems

Marie Granrud

M Granrud[1,2], *A Anderzen-Carlsson*[2,3], *B Bisholt*[2], *AK Steffenak*[1]
[1]Health and Nursing Sciences, Inland Norway University of Applied Science, Elverum, Norway
[2]Department of Health Science, Karlstad University, Karlstad, Sweden
[3]University Health Care Research Center, Örebro University, Örebro, Sweden
Contact: marie.granrud@inn.no

Background:

Mental health problems among adolescents account for a large portion of the global burden of disease and affect 10 - 20 % of children and adolescent worldwide. The public health nurse in the school health services is in the forefront for adolescents and play an important role in providing mental health. In order to identitfy and help the adolescents in secondary school with mental health problems the public health nurses are dependent on collaboration with other professionals. The aim of this study was to describe the variation in public health nurses perceptions of interprofessional collaboration related to mental health problems among adolescents in secondary school.

Methods:

This study has a qualitative design and individual interviews were analyzed with a phenomenographic approach. Eighteen public health nurses working in school health services, strategically selected from different counties, both urban and rural areas, were included to ensure variation in the phenomena.

Findings:

The analysis resulted in three descriptive categories: 'The formal structure has an impact on the interprofessional collaboration', 'The public health nurse is an important but not always self-evident partner in interprofessional collaboration' and 'The primary players are the teachers in collaborationń.

Conclusions:

The findings demonstrated that public health nurses are important but not always included in interprofessional collaboration and they were dependent especially of teachers to achieve good collaboration. There were variations in how public health nurses perceived interprofessional collaboration from school to school, which may give the adolescents with mental health different services. The knowledge from this study may be essential to strengthen public health nurses positions and presence in the school health service, which will benefit the adolescents with mental health problems.

Key messages:

- The public health nurse need to work actively to be included in interprofessional collaboration.
- The public health nurse are dependent on teachers and principals to achieve good collaboration.

The assessment of the functionality of public health specialists' activities in schools

Jurgita Vladickiene

J Vladickiene[1], *J Barkauskiene*[2,1]
[1]Health Management, Lithuanian Health Science University, Kaunas, Lithuania
[2]Medical Faculty, Utenos College, Utena, Lithuania
Contact: jurgita.vladickiene@gmail.com

Background:

The role of public health specialists (PHS) working at schools is continually growing to assure better health behavior and disease prevention in adolescent age. The aim of the study: to evaluate the functionality of health care activities performed by PHS at schools.

Methods:

Anonymous survey of PHS was conducted in April 2018. Participants of the survey represent PHS working at schools in Lithuania. In total 179 forms where distributed, 139 were included into analysis, response rate - 77.7%. The data were analyzed by using $\chi 2$ criterion and the statistical significance p.

Results:

PHS stated that past 12 months, bullying was the least important problem for children, but according to the prior plans prevention programs for it were organized most often (40.3%) and sports activity program - least often (21.6%), even though it's the most relevant children health problem these days. 52.3% of PHS claims that schoolchildren learn the most about keeping good health from them. 44.6% of PHS noted that they aren't able to do all their responsibilities during working hours, because paperwork takes up most of their time, and too little time remains for communication with the school community. One in three thinks, that they provide services for too many schools, one in seven assumes, that they have excessive requirements. Those who have longer work experience and too much workload were more unsatisfied with work in comparison with those with less work experience and proper workload ($p < 0.05$). Ability to communicate, knowledge and initiative are marked as the most important features, whilst work experience - as the least important, to pursue required activities of PHS.

Conclusions:

Health improvement activities of PHS working at schools do not fully meet the most important health problems of schoolchildren. PHS with longer experience and higher workload indicated more problems regarding their work compared with those that have less work experience and accurate workload.

Key messages:
- The assessment of the opinion of school community's on the most important children's health issues should be analyzed prior to preparing health activities plans in municipality level.
- Workload of public health specialists working at schools should be optimized according to health activities plans.

Are general practitioners willing to deprescribe in oldest-old patients with polypharmacy?

Katharina Tabea Jungo

KT Jungo[1], S Mantelli[1], Z Rozsnyai[1], E Reeve[2,3], RKE Poortvliet[4], J Gussekloo[4,5], N Rodondi[1,6], S Streit[1]
[1]Institute of Primary Health Care (BIHAM), University of Bern, Bern, Switzerland

[3]Canada College of Pharmacy, Faculty of Health, Dalhousie University, Halifax, Canada
[4]Department of Public Health and Primary Care, Leiden University Medical Center, Leiden, Netherlands
[5]Department of Internal Medicine, Section Gerontology and Geriatrics, Leiden University Medical Center, Leiden, Netherlands
[6]Department of General Internal Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland
Contact: katharina.jungo@biham.unibe.ch

Managing the growing number of oldest-old patients with multimorbidity and polypharmacy in primary health care poses an increasing public health challenge. Since inappropriate polypharmacy can harm patients' health, general practitioners (GPs) should regularly review patients' medications and, if necessary, deprescribe. This case vignette study evaluates the deprescribing decisions of GPs from 31 countries and compares the factors influencing GPs' deprescribing decisions.

We invited GPs to participate in an online survey, containing a) three cases of increasingly dependent oldest-old multimorbid patients with potentially inappropriate polypharmacy and b) Likert-scale questions assessing the importance of factors influencing deprescribing. We presented each case with and without history of cardiovascular disease (CVD). For each case, we asked whether GPs would deprescribe any medication and, if so, which one(s). We calculated percentages of GPs deprescribing at least one medication in each case, compared cases with/without CVD history and different levels of dependency in activities of daily living, and calculated the percentage of factors rated as important or very important.

Of 3175 invited GPs from 31 countries, 53% responded (N = 1'706) with a mean age of 50 years and 60% females. Results are preliminary, but despite some differences across GP characteristics (male/female, age) and across countries, GPs generally showed a high willingness to deprescribe in oldest-old patients (>80 years) with polypharmacy. GPs were more likely to deprescribe in patients with a higher level of dependency, in the absence of history of CVD, and when patients are on statins, proton-pump inhibitors or potentially inappropriate pain medication. Factors GPs rated as important or very important for the deprescribing decision were patients' quality of life, risks and benefits of medications, patients' life expectancy, and potential negative health outcomes resulting from deprescribing.

Key messages:
- Despite international differences, most GPs report they would deprescribe in older multimorbid patients with polypharmacy.
- The results will facilitate the development of interventions supporting general practitioners to deprescribe.

How to engage French professionals to undertake social responsibility at a local level?

Sylvain Gautier

S Gautier[1], Y Bourgueil[1]
[1]Mission RESPIRE (EHESP-IRDES-CNAMTS), Ecole des hautes études en santé publique, Saint-Denis, France
Contact: sylvain.gautier@sciencespo.fr

Background:
In France, primary care is organised according to the principles of private practice: independent providers, payment by fee for service, freedom of settlement... Successive reforms have introduced more regulation i.e. gatekeeping role for GPs, better recognition of professional groups, new forms of payment and promotion of team work and multi-professional practices. Today, the concept of Health Territorial and Professional Communities (HTPC) is becoming a key element of health care reform encouraging primary care professionals to meet with specialists and social workers at a larger level than practice. HTPC should address issues such as access to services, coordination of care and promoting of preventive actions toward populations. This implies change in the roles, skills, methods and resources needed on both professional and regulatory sides. This study explores levers of the professional commitment in the HTPC and resources necessary for it.

Methods:
We conducted a qualitative multiple case study in three French regions. Data was collected from thirty semi-structured interviews with key national informants, regional regulators and health professionals themselves.

Results:
Professional commitment emerges at a local level on a territory defined by the collaboration practices and habits following a bottom-up process. The integration of care relies on the size of the HTPC which allows them to know each other and to work together to improve access to care and patient's disease management. In order to achieve that, professionals claim to have access to administrative health data and to be able to analyze it. They need to develop news skills in management and group animation. The function and training of coordination professionals appear to be essential.

Conclusions:
The professional commitment in HTPC relies on professional empowerment toward collective activities. This requires autonomy, skills and new roles both for professionals and regulatory authorities.

Key messages:
- French government relies on professionals' investment at the territorial level by implementing HTPC to guarantee access to care and respond to population needs in primary care.
- HTPC implementation implies radical change for the professionals to undertake social and populational responsibility for which public health professionals should help to meet the challenge.

Impact of an intervention to activate unemployed people on the use of primary health care services

Pia Hakamäki

P Hakamäki[1], A Impinen[1], A Lounamaa[1], T Ståhl[1]
[1]The Welfare and Health Promotion Unit, National Institute for Health and Welfare, Helsinki, Finland
Contact: pia.hakamaki@thl.fi

Background:
Promoting well-being and health is a key policy instrument in municipalities. There are many ways to support the work ability of long-term unemployed people. Short term subsidized employment (300-500 €/person/month) being one widely used measure. The purpose was to study what kind of influence a short term employment has on the use of social and health care services of long-term unemployed people in sparsely populated area. Specifically, the aim was to investigate the use of primary health care services among people in subsidized employment, intervention (n = 67) and control group (n = 85) during five years period (2012-2016).

Methods:
Individual-level data were extracted from registers (age: 19-65 years old, gender: 61 % men, 39 % woman, N = 152). The use of primary health care was examined in the case study by means of annual averages, cumulative percentages and regression analysis.

Results:

According to preliminary results, there were differences in the prevalence of primary health care services use and how the use of services changed among intervention and control groups. The use of services in intervention group increased until the end of the intervention year, but decreased in the following year, 2016. The use of services in control group increased until 2016. Regression analysis was carried out to study the change; a year and an intervention for 2014-2016 were made as a predictor. It was found out that the number of visits increased each year by looking at both groups together (p = 0.012). The subsidized employment that started in 2014 had a statistically significant reducing effect on the use of services (p = 0.034) in intervention group in 2014-2016.

Conclusions:

Municipalities' health promotion and subsidized employment work can have positive impact on disadvantaged groups such as long-term unemployed people in sparsely populated area. Creating data for the use of services from local registers was very time consuming and challenging process, but possible.

Key messages:

- Promoting well-being and health is a key policy instrument in municipalities.
- Municipalities' health promotion and subsidized employment work can have positive impact on disadvantaged groups such as long-term unemployed people in sparsely populated area.

Can clinical coordination be improved through Participatory Action Research (PAR) interventions?

M Luisa Vázquez Navarrete

I Vargas[1], P Eguiguren[2], AS Mogollón-Pérez[3], I Samico[4], J López[5], F Bertolotto[6], P De Paepe[7], ML Vázquez[1]

[1]Health Policy and Health Services Research Group, Health Pol, Consortium for Health Care and Social Services of Catalonia, Barcelona, Spain
[2]Escuela de Salud Pública Dr. Salvador Allende Gossens, Universidad de Chile, Santiago de Chile, Chile
[3]Escuela de Medicina y Ciencias de la Salud, Universidad del Rosario, Bogotá, Colombia
[4]Grupo de Estudos de Gestão e Avaliação em Saúde, Instituto de Medicina Integral Prof. Fernando Figueira, Recife, Brazil
[5]Instituto de Salud Pública, Universidad Veracruzana, Veracruz, Mexico
[6]Facultad de Enfermería, Universidad de la República, Montevideo, Uruguay
[7]Prince Leopold Institute of Tropical Medicine, Antwerpen, Belgium
Contact: mlvazquez@consorci.org

Background:

Despite the effectiveness of Participatory Action Research (PAR) in reducing the gap between evidence and practice, its use to improve care integration is rare. The aim is to analyze the factors influencing the implementation of PAR interventions to improve clinical coordination in public health services networks of Brazil, Chile, Colombia, Mexico and Uruguay.

Methods:

A qualitative, descriptive-interpretative study was conducted in participating healthcare networks of each country. Focus groups and individual semi-structured interviews were conducted to a criteria sample of participants: members of Local Steering Committee (LSC)(29), professionals' platform (PP)(28), other professionals (49) and managers(28). Thematic content analysis was performed, segmented by country and themes.

Results:

Findings reveal that contextual factors, the PAR process and interventions' content were determinants in the implementation, interacting over time, and differing among experiences. On the one hand, institutional support (providing the necessary resources) together with the interest of professionals and managers in participating, emerged as influencing factors influenced by other factors related to: the system (alignment with policies; electoral cycle), networks (lack of time due to work overload; precarious employment conditions) and individuals (limited mutual knowledge and mistrust). On the other, some characteristics of the PAR process facilitated institutional support and motivation: professionals' participation in all activities, design flexibility and shared decision-making - also present when interventions were based on mutual adjustment - the LSC's leadership and the facilitating role of the research team.

Conclusions:

Evidence is provided that when some contextual elements converge the implementation of interventions through PAR processes can turn into a factor of motivation and cohesion, determinant for the adoption of clinical coordination interventions.

Key messages:

- Contributes to fill the knowledge gap in factors influencing the implementation of PAR interventions in healthcare.
- Provides a framework for analysis and recommendations for their implementation.

Intervention on knowledge and perception of hand hygiene among healthcare workers

Asma Ben Cheikh

A Ben Cheikh[1,2], S Ben Fredj[1,2], S Bhiri[1,2], H Ghali[1,2], S Khefacha[1,2], L Dhidah[1,2], M Ben Rejeb[1,2], H Said Latiri[1,2]

[1]Université de Sousse, Faculté de Médecine de Sousse, Sousse, Tunisia
[2]Department of Prevention and Security of Care, University Hospital Center of Sahloul, Sousse, Tunisia
Contact: asmasmams@yahoo.fr

Background:

Many studies conducted in healthcare settings with limited resources reported healthcare associated infections (HAIs) rates higher than in developed countries. Hand hygiene is considered as the most effective procedure for reducing infection in a wide variety of settings. The aim of this study was to assess the effectiveness of an intervention program to improve knowledge and perception of hand hygiene among healthcare workers (HCWs).

Methods:

We conducted a prospective before-and-after study design in university hospital Sahloul, Sousse, Tunisia, from January 2015 to December 2016. The same questionnaire, constructed by the WHO was distributed and collected at HCWs' workplace.

Results:

A total of 149 and 146 HCWs were enrolled, respectively at pre and post intervention. The majority was nursed women aged between 20 and 35 in pre intervention, whereas in post intervention the majority where physicians. Globally, our results showed tendencies toward improvement, but only two items were significant: the HW is the appropriate technique after injury (73.5% vs 86.8%; p = 0.006) and the hands of HCWs are the lead vehicle of HAIs (65.1% vs 83.6%; p = 0.01). On the other hand, judging by the HCWs' responses, the probably most effective intervention to enhance hand hygiene compliance was that an alcohol-based hand-rub is available at each point of patient care. In contrast, empowering patients to remind HCWs to perform hand hygiene was mostly rated to be the least effective intervention both in pre and post intervention.

Conclusions:

Our intervention to positively influence hand hygiene knowledge was unfortunately less effective than we had hoped it would be, which suggests a HCWs' reluctance to attend the training program.

Key messages:

- Hand hygiene is considered as the most effective procedure for reducing nosocomial infection.
- the intervention to positively influence hand hygiene knowledge was effective.

Assessment of unmet needs and barriers to end-of-life care provision in Kazakhstan

Lyazzat Toleubekova

L Toleubekova[1], B Crape[1], K Dauyey[1], D Argandykov[1], A Bekenova[1], M Madikenova[1], B Kaukenova[1], A Noskov[1]

[1]School of Medicine, Nazarbayev University, Nur-Sultan, Kazakhstan
Contact: lyazzat.toleubekova@nu.edu.kz

Introduction:

Palliative care, a holistic multidisciplinary approach for those persons with terminal diseases, providing relief for physical, emotional, psychosocial and spiritual suffering of both the patients and their families and to support the dignity of all involved in the process of dying. The purpose of this qualitative research project is to identify the barriers for end-of-life care provision in Kazakhstan and to provide recommendations on how to integrate and assure high quality palliative care for patients within the cultural context of Kazakhstan.

Methods:

Our proposed research project employed qualitative research methods, including semi-structured in-depth interviews using grounded theory. We conducted purposive recruiting with content analysis and semi-structured interviews until saturation was achieved. The interviews have been conducted at the University Medical Center (UMC) teaching hospitals, including National Research Center for Maternal and Child Health and the National Children's Rehabilitation Center. The total number of participants were 65 individuals, of whom 26 were medical doctors, 20 nurses, 7 speech therapists, 6 psychologists, 4 educators and 2 social workers. All participants had experience working with terminally ill patients, family members, and caregivers. The data was then translated into English. Analysis of the interview data have been performed by using the computer assisted software analysis package - NVivo. Institutional review board (IRB) approval of the Nazarbayev University has been received, assuring informed consent and confidentiality safeguards in the research.

Results:

The study findings indicate the evidence of growing demand in training of healthcare professionals, inadequate provision of pain relief and lack of public awareness about palliation as primary obstacles for palliative care development in Kazakhstan.

Key messages:

- The findings of the study are very important to help stakeholders to focus on the development of training opportunities for palliative care specialists.
- The results of the study help to develop milestones and concrete strategy for integration of palliative care services into the national healthcare system of Kazakhstan.

Does case management provides support for staff facing frequent users of emergency departments?

Michael von Allmen

M von Allmen[1], V Grazioli[1,3], M Kasztura[1], M Lemoine[1], O Chastonay[1], O Hugli[2], JB Daeppen[3], P Bodenmann[1]
[1]Department of Vulnerabilities and Social Medicine, University Center for General Medicine and Public Health, University of Lausanne, Lausanne, Switzerland
[2]Emergency Department, Lausanne University Hospital, University of Lausanne, Lausanne, Switzerland
[3]Department of Psychiatry, Lausanne University Hospital, University of Lausanne, Lausanne, Switzerland
Contact: michael.vonallmen@unil.ch

Background:

Frequent users of emergency departments (FUED; 5 ED visits during the preceding 12 months) account for a disproportionate part of ED visits, causing a wide range of work difficulties to ED staff potentially leading to FUED discrimination. Whereas case management (CM) tailored to FUED leads to a reduction in ED visits, CM impact on ED staff has not been explored yet. This study aimed to compare ED staff perceptions of FUED with and without dedicated CM support.

Methods:

Participants (N = 253) were ED staff (81 physicians; 172 nurses/assistant nurses) of two Swiss university hospitals, one with CM and one without CM support. Perceptions regarding FUED (i.e., knowledge and awareness of the issue extent; related work difficulties; FUEDs' legitimate use of ED resources) were measured with a 25-item online survey (4 to 10-level Likert scales). Multivariable regression analyses were conducted to 1) explore the associations between CM implementation and FUED perceptions, and 2) test the moderating effect of profession (physician or nurse/nurse assistant) on these associations. All analyses were adjusted by gender and years of practical experience.

Results:

Physicians with CM considered FUED as a less important problem (= .375, R2 = .11, p <.05) and rated their knowledge of FUED issue higher (= .245, R2 = .077, p <.05) compared to those without CM. In contrast, nurses without CM perceived fewer FUED-related work difficulties (i.e., feeling of failure and helplessness) than nurses with CM. (= -1.01, R2 = .06, p <.05) No significant difference was found regarding ED staff's perceptions of FUEDs' legitimate use of ED resources and frequentation, nor on nurses' knowledge of the issue.

Conclusions:

These results suggest that CM intervention for FUED is a potential source of support for ED physicians working with FUED. Further qualitative research is needed to explore why nurses without CM support reported feeling less failure and helplessness regarding FUED.

Key messages:

- By highlighting a different impact of CM on nurses' perception, this study illustrates where CM intervention might be improved.
- This study supports CM as a promising intervention for FUED by potentially having a positive impact on ED physicians' perception besides the one previously proved on FUEDs' number of visits and QOL.

Future Physicians and Cosmetic Medical Interventions

Nesrin Cilingiroglu

NP Erbaydar[1], N Cilingiroglu[1], MS Ak[2], MF Aksakal[2], A Bartu[2], YF Gunes[2], MA Oney[2], A Ozcan[2], MB Tumtas[2], HE Yilmaz[2]
[1]Department of Public Health, Faculty of Medicine, Hacettepe University, Ankara, Turkey
[2]Intern, Faculty of Medicine, Hacettepe University, Ankara, Turkey
Contact: nesrinc@hacettepe.edu.tr

Background:

International Union of Aesthetic Plastic Surgeons' survey-2017 showed Turkey is the second country among others in terms of numbers of cosmetic medical interventions (CMI) in Europe and ranks ninth worldwide. Therefore future physicians' (FT) perceptions are important on this topic as potential implementer and service user.

Objective:

Objectives are: To examine FPs (interns) personal CMI experience; practiced/observed CMI; their attitude towards CMI and related factors.

Methods:

Study is descriptive with 274 interns. Data collected by online survey contains 22 questions and acceptance of cosmetic surgery scale (ACSS) (Henderson and King, 2005).

Findings:

Of the interns, 51.5% were female; 47.8% perceived good economic status; 40.5% had cosmetic-surgery training; 23.0% had CMI (laser on skin and teeth interventions mostly); 39.7% of these interventions were performed in private clinics while some of them are realized in beauty centers; body-perception was found (75.5%) the main motive of CMI. There was a strong relation between CMI and gender. Female interns constituted majority (p = 0.01). Respondents who had CMI had the highest scores of ACSS ($p < 0{,}001$). It was found that ACSS is positively related to positive familial and social environment (p = 0,007); negatively related with strong traditional (p = 0,005) and religious beliefs ($p < 0{,}001$); positively related with the given importance of body-perception (p = 0,015). Media effect was found important factor on ACSS scores ($p < 0{,}001$).

Conclusions:
If the awareness of the quality, results, benefits and harms of CMIs is well established, it may be thought that there will be differences in attitude scale and less CMI performance. Therefore, it is necessary to constitute training programs on the different aspects of CMIs in medical curriculum.

Key messages:

- CMIs are not medically necessary and not a public-health issue and has economic burden.
- Awareness on the quality, results, benefits and harms of CMIs is should be well-clarified in the society.

Evaluation of minimum standards for communal catering in Styrian nursing homes

Christina Lampl

C Lampl[1], AL Aufschnaiter[1], M Hatz[1], W Gunzer[1], B Fuchs-Neuhold[1]
[1]FH JOANNEUM – University of Applied Sciences, Nutrition and Dietetics, Graz, Austria
Contact: christina.lampl@fh-joanneum.at

Background:
Nutritional standards in community catering facilities are essential for adequate quality of care. As part of the initiative GEMEINSAM G'SUND GENIESSEN of the Health Fund Styria, minimum standards for nursing homes were published. The aim was to investigate the current situation of the implementation of selected minimum standards for food and drink supply in Styrian nursing homes to create appropriate measures for healthy living for elderly people.

Methodology:
Of 81 defined minimum standards, two thirds were examined in the study (n = 54; 66.6 %). To get detailed insights into the current degree of implementation, the project team worked with a mixed- methods-basis, consisting of an online survey (n = 94; 41.4% of all Styrian nursing homes), 46 guideline interviews and 169 weeks of menu analysis.

Results:
Of the 54 minimum standards analysed, 34 were fulfilled (63.0%), nine were rather fulfilled (16.6%), five were rather not fulfilled (9.2%), four standards could not be fulfilled (7.4%) and two standards could not be investigated (3.7%). Nursing homes prefer seasonal and regional products, but pay less attention to the use of fair trade products or organic food. In addition, the food choice is determined by the preferences and acceptance of the residents, which are the main reasons for the low use of whole grain products and the rare offer of vegetarian dishes. With regard to the design of the menus, almost all plans are age-appropriate and attractively presented, but rarely meet the standard with regard to recommended labelling (e.g. alcohol aromas). Challenges in the daily practise are finding a way between the self-determination of the residents, the arranged diets as wells as meeting the minimum standards.

Conclusions:
Results indicate that minimum standards in nursing homes are taken into account. In order to achieve a comprehensive implementation, further development of the standards as well as information and awareness-building interventions are needed.

Key messages:

- Challenges in the daily practise are finding a way between the self-determination of the residents, the arranged diets as wells as meeting the minimum standards.
- The range of vegetarian dishes, dishes with legumes and wholemeal products should be focused in the future. In addition, the provision of tools (age-and target-group-specific-menus) is recommended.

Waiting times in cardiology and quality of care: analysis of performances in an Italian hospital

Elena Olivero

E Olivero[1], F Bert[1,2], C Corezzi[1], P Rossello[1], P Alaria[2], R Siliquini[1,2], A Scarmozzino[2]
[1]Department of Public Health Sciences, University of Turin, Turin, Italy
[2]Molinette Hospital, AOU City of Health and Science of Turin, Turin, Italy
Contact: elena.olivero@unito.it

Background:
The identification of diseases in an early stage is essential to improve prognosis and survival of patients. Consequently, waiting times for cardiological performances are widely recognized in Europe as evaluation items for healthcare quality. Our study aims to analyse waiting times of the main procedures in the cardiology ward of a huge hospital of Northern Italy and to compare them with the regional benchmark.

Methods:
Data of the cardiology ward of "Molinette" hospital (Turin, Italy) about the waiting times for clinical procedures in the period 2016-2017 were collected. In particular, we gathered number of health care services and mean waiting times (MWT) for "Echocardiography" (EC), "First Cardiological Visit" (FCV), "Holter ECG" (HECG), "Percutaneous Transluminal Coronary Angioplasty performed within 2 days for people with myocardial infarction" (PTCA). We compared then our results with the benchmarks identified by the regional law.

Results:
In the period considered, in "Molinette" hospital 11,565 ECs were performed, with a MWT of 31 days in 2016 and 16 days in 2017, well below the benchmark (40 days). The total number of FCVs was 5,156 with a MWT of 18 and 13 days in 2016 and 2017 respectively, again under the benchmark (30 days). The HECGs were 3,805, with a MWT of 53 (2016) and 32 (2017) days (benchmark 40 days). PTCAs performed within 2 days (benchmark 85%) were 160 (77.7%) in 2016 and 138 (85.2%) in 2017.

Discussion:
In 2017, the waiting times of "Molinette" hospital were inferior to the regional benchmarks, for all the cardiological procedures considered. Shorter MWTs allow a more rapid planning of further diagnostic tests and treatments and, therefore, a consequent better quality of care. It's important for European hospitals to assess and compare these indicators in order to guarantee a fast and appropriate care to their patients.

Key messages:

- Waiting times are an indicator of early diagnosis and treatment and are useful to assess the quickness and quality of health care provided in European hospitals.
- Cardiological procedures in "Molinette" hospital of Turin are provided with waiting times shorter than benchmarks. It would be interesting to compare these results with other big European hospitals.

Using routine data to benchmark quality and outcomes of diabetes care in the EU HEALTHPROS project

Fabrizio Carinci

F Carinci[1,2], B Meza Torres[1], SG Cunningham[3], J Mainz[4], O Groene[5], M Massi Benedetti[6], NS Klazinga[7], D Kringos[7], S de Lusignan[2]
[1]Department of Clinical and Experimental Medicine, University of Surrey, Guildford, UK
[2]Department of Statistical Sciences, University of Bologna, Bologna, Italy
[3]Clinical Technology Centre, University of Dundee, Dundee, UK
[4]Aalborg University Hospital, Aalborg University, Aalborg, Denmark
[5]Optimedis, Hamburg, Germany
[6]Hub for International health ReSearch, Perugia, Italy
[7]Academic Medical Centre, University of Amsterdam, Amsterdam, Netherlands
Contact: f.carinci@surrey.ac.uk

Background:
The EU-funded Marie Curie project HEALTHPROS aims to foster a new generation of "Healthcare Performance Intelligence Professionals" through a cohesive stream of 13 doctoral projects (www.healthpros-h2020.eu). Over 48 months, researchers will investigate key levers of healthcare improvement in 7 different countries, using methods drawn

from the diverse fields of biostatistics, medical informatics and health services research.

Objectives:

To describe barriers and enablers in the conduction of two doctoral projects aimed at exploring the impact of personal risk factors and organizational arrangements on lower extremity amputations in diabetes, through the use of large-scale databases from England, Scotland, Denmark and Germany.

Results:

The research plan included a systematic review, structured comparison of data sources, predictive modelling and software development for automated international comparisons. Barriers encountered by researchers were: knowledge and access to data sources from different countries, dealing with data protection rules and the ability to carry out international comparisons when individual records are not easily allowed to leave national boundaries. Enabling factors included: a targeted educational process for risk modelling in diabetes and a multidisciplinary support team to help doctoral students overcoming the above barriers across different sites. Further clinical insight and contextual knowledge of data systems in place at different locations were needed in addition to the statistical, epidemiological and technical skills initially foreseen by the program.

Conclusions:

The success of studies within a general educational program on health systems performance may depend from the continued support of a multidisciplinary team helping students in their educational process as well as with the practicalities of their research. International comparisons using routine data may require prioritisation to meet the tight timelines of doctoral theses.

Key messages:

- Academic programs for international comparisons in health care may be hampered by different type of barriers including technical aspects, legal regulations and a range of contextual factors.
- The establishment of multidisciplinary support teams may be essential for training doctoral students aiming to conduct international comparisons using routine data.

Accessibility of early diagnostics for children with a developmental disorder in Flanders, Belgium

Eva Cloet

E Cloet[1,2], M Leys[1]
[1]Public Health, Vrije Universiteit Brussel, Jette, Belgium
[2]Paediatric Neurology, Universitair Ziekenhuis Brussel, Jette, Belgium
Contact: eva.cloet@vub.be

Background:

20% of all children suffer a neurodevelopmental delay or disorder (NDDD) worldwide. Early multidisciplinary diagnostics, early intervention and timely diagnostics along the rehabilitation trajectory are needed to improve the child's functioning and participation. In Flanders, Belgium, 6 types of public organizations (164 service points in the region) offer multidisciplinary diagnostics of NDDD for children. However the objective of timely diagnostics for the population is not realized.

Methods:

A qualitative thematic analysis identifies the criteria of Federal and Flanders' regulations for publicly accredited and funded organizations providing multidisciplinary diagnostics for children with (suspected) NDDD. A survey was sent in different settings on waiting periods and perceived determinants hampering early diagnostics These results were discussed and validated by experts in focus groups.

Results:

Average waiting times for diagnostics run up to 1 year before a diagnostic trajectory can be started. Regional differences occur in the availability of diagnostic services. Formal regulations hamper the development of collaborative networks and an integrated health services model offering accessible diagnostics along NDDD trajectories. The field lacks public health services strategies to provide accessible, efficient and effective diagnostics for a complex range of NDDD target groups

Conclusions:

Coordination of services providing multidisciplinary diagnostics for children with (suspected) NDDD is needed. A health services approach supporting mandated regional networks will improve the accessibility of early and timely diagnostics.

Key messages:

- Development of collaborative networks of different types of services offering diagnostics will improve the accessibility of early and timely multidisciplinary diagnostics for children with NDDD.
- Better accessibility to multidisciplinary diagnostics will improve long term outcome for children with NDDD.

Mergers of primary care organizations: a systematic review of the literature

Domenico Pascucci

D Pascucci[1], A Sindoni[2], C De Vito[2], G Damiani[1,3]
[1]Institute of Public Health, Section of Hygiene, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Department of Public Health and Infectious Diseases, Sapienza Università di Roma, Rome, Italy
[3]Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy
Contact: domenico.pascucci@outlook.it

Background:

Mergers as large-scale collaborations in primary care organizations have become a commonplace in developed countries to offer economies of scale and more efficient delivery of care to population. The aim of this systematic review is to summarize the scientific evidence on the relationship between the increase in the size of organizations providing primary care services and their performance.

Methods:

The PICO model was adopted and three electronic databases (Medline, Scopus, ISI Web of Knowledge) were searched using appropriate keywords. Screening by title and abstract and data extraction were performed by two independent investigators. Articles, written in English, evaluating the performance after increasing the size of an organization were included. Selected articles were assessed for quality and risk of bias using the National Institutes of Health Quality Assessment Tool for Observational Cohort and Cross-Sectional Studies. Process and outcome quality indicators were used for evaluation.

Results:

From a total of 1337, 12 studies met the inclusion criteria and 103 indicators were identified: 59.2% did not show any variation, 33.9% improved significantly after the merger, 6.9% worsened after the merger. In particular, diabetes care did not show any statistically significant variation in 40.0 % of the indicators, while 10.0 % showed an improvement and 10.0% a worsening in clinical outcomes. A significant negative association was found between practice list size and reported non-urgent or urgent doctors' availability ($P < 0.05$, both). The process of merging also created perceptions of takeover and had a negative effect on staff.

Conclusions:

The effects of mergers are conflicting and there is little evidence that the performance is associated with the size of the structures involved. Assessment on the impact of primary care mergers should to be related to the population needs and the context where these processes are carried out.

Key messages:

- Merging processes may lead to contrasting results.
- To assess periodically and systematically the impact of mergers in a continuous quality improvement cycle.

Keeping up with the codes; accounting for quality in cancer patient pathways (CPPs) in Norway

Erna Håland

E Håland[1]*, L Melby*[2]
[1]Department of Education and Lifelong Learning, NTNU, Trondheim, Norway
[2]SINTEF, Trondheim, Norway
Contact: erna.haland@ntnu.no

Background:

Standardised cancer patient pathways (CPPs) were introduced in Norway in 2015. CPPs are national standardised patient pathways which are discipline- and target-based (28 cancer diagnoses), aiming to minimize waiting times and make cancer care more predictable and secure for patients. One important part of the CPPs are different codes aimed at measuring time in the different phases of the pathway. These codes are reported to the Norwegian directorate for health and are made public on a national web site. On the basis of these reports hospitals across the country can be compared regarding compliance to timescales. From a political and bureaucratic level, the codes are seen as signs of quality, and hence very important.

Methods:

In this paper, we present preliminary results from a project which is evaluating the introduction of CPPs. Based on interviews with administrative staff responsible for coding and with other health personnel (physicians, nurses, clerical workers and managers) in different hospitals, we present experiences with and perceptions of coding practices.

Results:

We find that even though the coding manual is presented as a universal tool implying standardised coding practices, there is a multitude of coding practices (which makes comparison between hospitals challenging). The coding represents a massive bureaucratic workload for the dedicated staff, raising concerns if their time is spent on the most important issues.

Conclusions:

The codes are seen as timescales set according to logistics and not according to what is medically safe - and some of the health personnel argue that these timescales have nothing to do with quality. However, they still recognize that keeping the timescales might be important for the patient experience.

Key messages:

- Standardised coding are often not standardised, but contains a multitude of practices.
- These practices need to be explored in order to understand if and how codes can be seen as signs of quality.

Nursing processes analysis in district hospital in Lithuania

Jurgita Vladickiene

J Vladickiene[1]*, A Stonkeviciute*[1]
[1]Faculty of Public Health, Lithuanian Health Science University, Kaunas, Lithuania
Contact: jurgita.vladickiene@gmail.com

Background:

The aim of the study - to evaluate the time devoted to the activities of therapeutic profile nursing and wastes in the nursing processes.

Methods:

Time-and-motion study was applied for investigation of clinical workflow in nursing at district hospital in neurology and internal medicine departments. A total of four nurses, two nurses from each department, were observed. Duration of observation was 2 940 minutes (49 hrs).

Results:

Nurses devote most of their time to administering medicines. It has been noted that there are many additional, unnecessary actions in this process. Likewise nursing staff devotes a lot of time to documentation management work: refills the same dossier when the information is recorded in paper forms, and then transfer it to the computers. For communication with patients, nursing staff spend a very small part of their working time and it is due to insufficient staff and stress and fatigue of the nurses. It is observed that the nurses of neurology and internal medicine departments spent 50.3 percent of their working time for a direct patient care, 19.3 percent of time - for indirect patient care, 22.3 percent for personal time and 8.0 percent for unit-related functions. According to the Lean methodology waste of overproduction, waiting, defects, bureaucracy, transportation, motion and human potential were identified in these departments.

Conclusions:

Nurses of neurology and internal medicine departments spend most of their time for direct patient care and the least of their time for unit-related duties. Seven out of eight types of waste prevails in therapeutic departments of the district hospital.

Key messages:

- Adaptation of the Lean methodology of 'Visual Management' may aid for optimizing the process of medication administration and diminishing the paper work of nurses.
- The manifestation of the stress and fatigue of the nurses could be reduced if the workloads of nurses were adjusted and adequately distributed.

Reasons for cervical cancer screening participation among Turkish- and Moroccan-Dutch: focus groups

Eline Marchena

E Marchena[1]*, N Hamdiui*[1]*, ML Stein*[1]*, JE van Steenbergen*[1,2]*, M van den Muijsenbergh*[3,4]*, A Timen*[1,5]
[1]National Coordination Centre Communicable Disease Control, RIVM, Bilthoven, Netherlands
[2]Centre for Infectious Diseases, Leiden University Medical Centre, Leiden, Netherlands
[3]Program Prevention and Care, Pharos: Dutch Centre of Expertise on Health Disparities, Utrecht, Netherlands
[4]Department of Primary and Community Care, Radboud University Medical Center, Nijmegen, Netherlands
[5]Athena Institute Research on Innovation and Communication, VU University Amsterdam, Amsterdam, Netherlands
Contact: elinemarchena@gmail.com

Background:

Cervical cancer (CC) is ranked fourth most frequently diagnosed cancer in women worldwide. Compared to the 79% CC screening participation rate of native Dutch women, the rate of 64% among Turkish- and 53% among Moroccan-Dutch women is considerably lower. Our aim was to explore reasons for CC screening (non)participation of Turkish- and Moroccan-Dutch women, and their attitude towards self-sampling.

Methods:

Six focus groups were conducted in March and April 2019 with Turkish (n = 25) and Moroccan (n = 20) women in the Netherlands, aged 30-60 years. Questions were based on an extended Health Belief Model. Discussions were transcribed verbatim and thematically analysed.

Results:

We found that women lack knowledge and awareness about CC. Barriers for screening were lack of a good command of the Dutch language, having a male as general practitioner, fatalism, shame and taboo related to the intimate procedure, and the association of CC with lack of femininity and infertility. Other barriers were fears of the test result, cancer, suffering, death, and leaving their children behind after death. Facilitators were perceived severity of disease, social support, and short procedure time. Additional religious facilitators included the responsibility to take care of one's own health using medical facilities that God provided. Differences were found between Turkish and Moroccan women, such as lack of a good command of the Dutch language. Conflicting attitudes were found regarding self-sampling. Although perceived easy and accessible, women were hesitant whether they could sample correctly. Overall, women preferred a physician-taken smear to a self-sample.

Conclusions:

Several barriers and facilitators for CC screening participation were identified that can be used to design tailored information materials. Women's doubts about incorrect self-sampling should be taken into account to encourage self-sampling among nonparticipating Turkish and Moroccan women.

Key messages:

- Important barriers and facilitators were identified that can be used to well-inform Turkish and Moroccan women.
- To promote self-sampling, women's attitudes on their self-efficacy should be explored.

Waiting times for diagnosis and surgery in a large obstetric-gynecological hospital in Italy

Fabrizio Bert

G Scaioli[1], F Bert[1,2], C Plazzotta[3], M Corezzi[1], G Voglino[1], G La Valle[2], G Rabacchi[3], S Falco[2], A Scarmozzino[2], R SIliquini[1,2]

[1]Department of Public Health Sciences, University of Turin, Turin, Italy
[2]Molinette Hospital, AOU City of Health and Science of Turin, Turin, Italy
[3]Sant'Anna Hospital, AOU Ciy of Health and Science of Turin, Turin, Italy
Contact: fabrizio.bert@unito.it

Issue:

Diagnostic testing and surgical waiting times are related to quality of healthcare services. An extension of waiting times, indeed, could lead to a diagnostic or therapeutic delay, with potential consequences on patient health outcomes. Several policies have been implemented in different European countries in order to improve these indicators. Our study aims to analyse the waiting times of the largest obstetric and gynaecological hospital of Northern Italy, in order to identify potential issues in women's health services.

Description of the problem:

Data of "Sant'Anna Hospital" (Turin, Italy) about the waiting times in the period 2016-2017 for outpatient and surgical services addressed to women were collected. Specifically, number of health care procedures and mean waiting times (MWT) for "Obstetric-Gynaecological Echography" (OGE), "First Endocrinological Visit" (FEV), "First Gynaecological Visit" (FGV), "Surgical Intervention for Breast Cancer" (SIBC) and "Surgical Intervention for Uterus Cancer" (SIUC) were retrieved. Results were compared with the benchmark identified by the regional law.

Results:

A total of 21,735 OGEs were performed, with a MWT of 3 days in 2016 and 5 days in 2017, below the benchmark (11 days). The total number of FEVs was 1,234, with a MWT of 19 and 23 days in 2016 and 2017 respectively, again below the benchmark (30 days). The FGVs were 21,096 with a MWT of 9 (2016) and 24 (2017) days (benchmark 30 days). The number of SIBCs (N = 89) performed within 30 days (benchmark) were 87 (98% of SIBCs), while SIUCs (N = 90) were 84 (93%).

Lessons:

The waiting times of the "Sant'Anna hospital" were, for all the performances considered, shorter than the regional benchmarks. This is an indicator of the quickness of diagnosis and treatment and, indirectly, of the quality of care. An international comparison among the main European hospitals should be encouraged in a perspective of continuous improvement of health care provided to European citizens.

Key messages:

- Diagnostic testing and surgical waiting times are useful to assess the quickness and quality of health care provided in European hospitals.
- "Sant'Anna hospital", leader for women's health care, provides care with waiting times shorter than benchmarks. It would be interesting to compare its results with other large European hospitals.

Inequalities in the utilisation of primary and specialist physicians in Europe - a systematic review

Sara Schröder

SL Schröder[1], J Hoebel[2], J Roick[1], J Markert[1], J Spallek[3], O v.d. Knesebeck[4], M Richter[1]

[1]Institute of Medical Sociology, Martin Luther University Halle-Wittenberg, Halle (Saale), Germany
[2]Department of Epidemiology and Health Monitoring, Robert Koch Institute, Berlin, Germany
[3]Department of Public Health, Brandenburg University of Technology Cottbus-Senftenberg, Senftenberg, Germany
[4]Institute of Medical Sociology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany
Contact: sara.schroeder@medizin.uni-halle.de

Background:

The evidence on inequalities in health clearly shows that people with lower socioeconomic status (SES) have poorer health and higher mortality. Nevertheless, generalized evidence for inequalities in healthcare is lacking. So far, the international literature was only summarised with regard to inequalities in the utilisation of disease-specific treatment. Therefore, our aim was to synthetize the literature on socioeconomic inequalities in the utilisation of primary and specialist physicians in the general population.

Methods:

This systematic review searched Medline und Web of Science from 2004 to 2018. Articles that reported quantitative data on the association of SES with utilisation of primary or specialist physicians in Europe were included. Title and abstract screening were performed by two independent researchers and 50 full texts are currently sifted whether they fulfil the inclusion criteria.

Results:

The studies analysed utilisation of physicians in terms of probability or frequency. The initial check of the studies indicates that socioeconomic inequalities in the utilisation of physicians differ between primary and specialist care. Specialist physicians were found to be visited with a higher probability and more often by the least disadvantaged in most studies. Inequalities in the utilisation of primary physicians revealed to be more diverse with a weak pattern of equally distributed probability of GP visits and more frequent utilisation by the disadvantaged.

Conclusions:

The preliminary results indicate that pro-rich utilisation seems to be more pronounced in visiting specialists compared to primary health care. Aiming to reduce inequalities in healthcare, public health actions might primarily focus on reaching a needs-based consultation of specialist physicians.

Key messages:

- Socioeconomic inequalities in the utilisation of physicians exist and differ between primary and specialist care.
- Inequalities to the disadvantage of the population with low SES are more pronounced in the utilisation of specialists compared to general practitioners.

Compliance with smoke-free policy at tuberculosis facilities in Armenia: a mixed-methods study

Zaruhi Grigoryan

Z Grigoryan[1], V Hayrumyan[1], Zh Sargsyan[1], A Harutyunyan[1]

[1]Turpanjian School of Public Health, American University of Armenia, Yerevan, Armenia
Contact: zgrigoryan@aua.am

Background:

Smoke-free environments in tuberculosis (TB) facilities promote a tobacco-free lifestyle among patients and healthcare providers and advance their healthy image. Though the national law of Armenia prohibits indoor smoking in healthcare facilities, enforcement of the law is still insufficient. This study aimed to explore compliance with the smoke-free policy in TB facilities in Armenia.

Methods:

An exploratory sequential mixed-methods study was conducted. Overall 21 TB physicians and five key informants in the field of TB and tobacco control participated in qualitative interviews. To further quantify and validate the findings, structured observations of smoke-free policy implementation were conducted in 36 facilities.

Results:

All physicians expressed a positive attitude towards the smoke-free environment and were satisfied with the level of implementation of a smoke-free policy in their TB facilities. According to the respondents, they already have smoke-free environments established in their facilities. ''No smoking'' signs, warnings about health consequences and financial penalties, and pictures of damaged lungs were the most common measures against indoor smoking. However, only in 17.1% (n = 6) and 8.6% (n = 3) of observed TB facilities there were posted ''No smoking'' signs and financial penalties, respectively. In 5.7% (n = 2) of facilities, the research team found ashtrays inside the building, and in 20.0% (n = 7) of facilities, there were smoking patients, physicians, and visitors.

Conclusions:

While the qualitative study indicated good compliance, the quantitative findings were controversial with this regard. In fact, in most of the facilities, the smoke-free policy was not properly implemented and enforced. Additional efforts are needed to harmonize the current practices with national policies and recommendations.

Key messages:

- There was a discrepancy between practices reported by physicians and the actual observed compliance.
- Further interventions are needed to ensure 100% compliance with smoke-free policy in TB healthcare facilities.

A qualitative study on cancer patientś experiences with financial burden and financial distress

Sara Schröder

SL Schröder[1]*, N Schumann*[1]*, M Richter*[1]
[1]Institute of Medical Sociology, Martin Luther University Halle-Wittenberg, Halle (Saale), Germany
Contact: sara.schroeder@medizin.uni-halle.de

Background:

Financial toxicity was hardly examined in the context of public health. It is proven that financial distress following a cancer diagnosis can have an impact on the quality of life and mortality. Additionally, it was found that subjective indicators of financial toxicity have a stronger effect than objective indicators. Nevertheless, less is known about how higher costs can impact on the individual patient's well-being. The aim of this study was to analyse the major drivers that lead from financial consequences to subjective financial distress in a country with statutory health insurance.

Methods:

Qualitative semi-structured interviews were conducted with 39 cancer patients, aged between 40 and 86 years, in Germany. Inductive content analysis of data was performed and the individual patient's pathways are recently compared and contrasted.

Results:

Above all, we found that financial distress is not only induced by higher costs and lower available money. Moreover, independently of whether patients experienced any financial decline, they experienced making financial adjustments and feeling financially stressed. The preliminary results show that the patient's ability of good money management and trust in one's own skills being able to get along with less money might predict psychosocial consequences.

Conclusions:

Screening instruments for financial toxicity are important to effectively detect patients whose quality of life might be worsened by their financial situation. It might be that rather financial skills than the amount of costs are important indicators of financial distress.

Key messages:

- Even cancer patients experiencing almost no financial decline during the period of cancer treatment might experience lower quality of life caused by financial distress.
- The ability and trust in oneself money management might have the strongest impact on subjective financial stress.

Genetic services for Hereditary Cancer: a systematic review of Patient Reported Outcomes studies

Erica Pitini

E Pitini[1]*, E D'Andrea*[2]*, A Rosso*[1]*, A Massimi*[1]*, B Unim*[1]*, C De Vito*[1]*, C Marzuillo*[1]*, P Villari*[1]
[1]Department of Public Health and Infectious Diseases, Sapienza University, Rome, Italy
[2]Harvard TH Chan School of Public Health, Boston, USA
Contact: erica.pitini@uniroma1.it

Background:

Genetic services for Hereditary Breast and Ovarian Cancer (HBOC) have become part of clinical and public health practice. Nevertheless, the evaluation of such services, including genetic testing and counseling, is challenging as they rarely affect health status measures (e.g. mortality and morbidity). A possible way is using Patient Reported Outcomes (PROs) i.e. subjective reports coming from patients, directly attributable to genetic services. We performed a systematic review to explore the use of PROs in HBOC genetic services.

Methods:

We searched Pubmed, Scopus, and ISI Web of Knowledge for observational studies using PROs to assess standard genetic counseling (i.e. in person and individual) for HBOC.

Results:

We identified ten surveys from various countries (USA n = 5; Europa n = 6), published between 2000 and 2018 and mainly conducted in Teaching hospitals and Cancer Research and Treatment Institutes (n = 9). The majority assessed pre-test counseling (n = 6) with diagnostic or predictive purpose. The most frequently measured outcomes were patient satisfaction (n = 9), adherence to recommended interventions (n = 3), information sharing with relatives (n = 3); disease risk perception (n = 2), and psychosocial distress (n = 2). Six studies adopted standardized PROs collection tools: the most common were the Genetic Counseling Satisfaction Scale and the Hospital Anxiety and Depression Scale. Questionnaires were mainly administered by post, soon after genetic counseling or up to seven years later. Overall, patients seem satisfied with genetic counseling. Nevertheless, more attention to the psycho-social aspects of genetic testing is needed.

Conclusions:

PROs are very promising for the assessment of HBOC genetic services. Their routine use could provide important elements to improve the quality and the patient-centeredness of genetic services. Emerging information and communication technologies will help this process by making it easier collecting patient data.

Key messages:

- Precision medicine, where medical decisions are tailored to an individual's characteristics, including the patient's genetic profile, is becoming a paradigm for chronic diseases, particularly cancer.
- PROs are expected to be increasingly used as a measure of performance in order to drive the changes in how clinical genetic services, and healthcare in general, are organized, delivered and founded.

Paying attention to personnel in organizational changes: the impact of hospital mergers

Leuconoe Grazia Sisti

LG Sisti[1]*, M Mariani*[1]*, C De Vito*[2]*, C Isonne*[2]*, A Nardi*[2]*, R Mete*[3]*, P Villari*[2]*, W Ricciardi*[1,4]*, G Damiani*[1,4]
[1]Department of Public Health, Section of Hygiene, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Department of Public Health and Infectious Diseases, Sapienza Università di Roma, Rome, Italy
[3]ASL Roma 2, Rome, Italy
[4]Fondazione Policlinico Universitario A.Gemelli IRCCS, Rome, Italy
Contact: leuconoe.sisti@gmail.com

Background:

The importance of paying attention to personnel satisfaction for the well-being of an organization is clearly stated also in healthcare organization. The trend of mergers of healthcare organizations represents an evident case of organizational change that could undermine personnel satisfaction if not adequately managed. The aim of our study was to investigate the impact of hospital merger on personnel perceptions and satisfaction.

Methods:

A systematic review of the literature was carried out by querying scientific databases and grey literature. A search string was built using keywords including: merger, healthcare, personnel, satisfaction and synonyms. Inclusion criteria were primary studies reporting the outcome of interest and set in hospitals that has undergone a merger. Studies characteristics such country setting, design and time frame of the study, number and role of personnel interviewed and main findings were extracted and narratively synthesized.

Results:

Search resulted in 3662 studies of which 9 were finally included in the analysis. Studies were mainly represented by post-merger qualitative research (77.8%) of which 55.6% semi and 54.4% structured interviews. Sample size ranged from 14 to 3119 and was represented by unspecified employees (55.6%), nurses and hospital executives (22.2% both). Findings showed that hospital executives consider merger positively especially regarding increased negotiation skills and costs reduction. Conversely, the other personnel mainly expressed critical issues as differences in organization of hospitals merged, goals and confirmation uncertainty, communication impairment and especially no involvement in follow-up in the post-merger phase.

Conclusions:

The merger process strongly impacts healthcare personnel satisfaction, depending on the role played in the organization. If an initial enthusiasm and staff engagement in pre-merger phase is seen, this is not generally followed by their proper involvement over time.

Key messages:

- As personnel satisfaction and perceptions are strongly related to healthcare quality, they represent a central point in the merger process of healthcare organization.
- More attention must be paid to follow-up staff satisfaction after the merger in a continuous staff engagement to ensure the success of merger process as well as that of all organizational changes.

Obstetrical complications treated in the maternities of the region of Sousse (Tunisia)

Jihene Sahli

M Limam[1], J Sahli[1], F Hachani[2], M El Ghardallou[1], M Mellouli[1], M Bachraoui[1], C Zedini[1], H Khairi[2], A Mtiraoui[1], T Ajmi[1]

[1]Department of Familial and Community Medicine, University of Sousse, Faculty of Medicine of Sousse, Research Laboratory ''LR12ES03'', Sousse, Tunisia

[2]Department of Gynecology and Obstetrics, University of Sousse, Faculty of Medicine of Sousse, Research Laboratory ''LR12ES03'', sousse, Tunisia

Contact: dr-jihene19@hotmail.com

Background:

About 800 women die each day worldwide due to complications related to pregnancy, childbirth or in the postpartum period. The objective of this study was to describe the activity of the public maternities in the Governorate of Sousse (Tunisia) and to identify obstetrical complications treated in these facilities.

Methods:

A cross sectional study of all public health facilities, which performed deliveries in Sousse was conducted in 2017 (Five maternities: one University maternity and four peripheral ones). Data were collected by reviewing clinical records and registers of these maternities for the year 2016.

Results:

In total, in the health visited structures, there were 13427 deliveries in 2016, the majority of them (78.8%) took place at the university maternity of Farhat Hached hospital. Of these deliveries, 3397 were performed by caesareans (25.3%). In 2016, there were three maternal deaths and 69 very early neonatal deaths. There were 2036 direct obstetric complications treated in the five maternities visited. The most frequently encountered direct complications were: 'obstructed/prolonged labor' (41.21%), 'severe pre-eclampsia/eclampsia' (19.5%) and 'ante and postpartum haemorrhage' (15.18%). The most encountered indirect obstetrical complications were: gestational diabetes and anaemia.

Conclusions:

The reduction of maternal and neonatal mortality requires the existence of a functioning basic health care system that provides all pregnant women and their newborns with timely access to skilled care, particularly when a complication occurs. The provision of this qualified care requires also the presence of qualified personnel working in a suitable professional environment.

Key messages:

- The majority of obstetrical complications occur in university maternity and this is due to excessive references from peripheral maternities.
- Peripheral maternities need to be strengthened with material and human resources.

Time trends of primary care quality across Portuguese regions: using prevention quality indicators

João Vasco Santos

JV Santos[1,2,3], J Viana[1,2], J Souza[1,2], M Lobo[1,2], A Ramalho[1,2], M Gonçalves-Pinho[1,2], A Freitas[1,2]

[1]MEDCIDS – Department of Community Medicine, Faculty of Medicine, University of Porto, Porto, Portugal

[2]CINTESIS – Center for Health Technology and Services Research, Porto, Portugal

[3]Public Health Unit, ACES Grande Porto VIII Espinho-Gaia, Vila Nova de Gaia, Portugal

Contact: jvasco.santos@gmail.com

Background:

Primary care quality is one of the main dimensions of primary care performance and can be evaluated by several methods, e.g. studying hospitalizations for conditions that could be treated, or less severe, if appropriately managed in primary care. Accordingly, the Agency for Healthcare Research and Quality (AHRQ) developed prevention quality indicators (PQIs). In this study, we aimed to compare PQIs and their time trends across Portuguese regions.

Methods:

We performed a retrospective study, using all adult public hospital discharges in mainland Portugal, between 2011 and 2015. PQI rates for the overall (PQI 90) and composite indicators (i.e. 91 - acute, 92 - chronic, 93 - diabetes) were computed using AHRQ specifications. These rates were compared between the 5 Portuguese NUTS 2 regions of residence.

Results:

From the total of 407,792 hospital discharges in mainland Portugal (2011-2015) 11.9% comprised the selected PQIs, the majority related the acute composite PQI, followed by the chronic composite PQI. The hospitalization rate of the overall PQI increased from 999.5 hospitalizations (2011) to 1231,0 hospitalizations/100,000 inhabitants (2015), with an increase in all NUTS 2 regions. In 2015, while Algarve and North had the lowest PQI rates, Centro and Alentejo showed the highest ones.

Conclusions:

Between 2011 and 2015, there was an increasing trend of overall and composite PQI rates. Also, important differences between Portuguese regions were found that must be further studied.

The authors thank the support given by the Project 'POCI-01-0145-FEDER-030766' (1st.IndiQare - Quality indicators in primary health care: validation and implementation of quality indicators as an assessment and comparison tool), funded by Fundação para a Ciência e a Tecnologia (FCT) and co-funded by Fundo de Desenvolvimento Regional (FEDER) through Operacional Competitividade e Internacionalização (COMPETE 2020).

Key messages:

- Between 2011 and 2015, overall prevention quality indicator rate increased in Portugal.
- There are great differences between Portuguese NUTS 2 regions regarding prevention quality indicators.

DM Health systems and economics

Individual Versus Area Level Social Risk Measurement in the General French Population

G Mercier

G Mercier[1], *C Quantin*[2], *M McWilliams*[3]
[1]CHU de Montpellier, Montpellier, France
[2]CHU de Dijon, Dijon, France
[3]Harvard Medical School, Boston, USA
Contact: gregoire_mercier@hotmail.com

Background:

Ongoing health policy changes include a move towards alternative delivery and payment models. In addition, the emphasis is put on social determinants as part of performance measurement and payment calibration. Most payers and policy makers rely on area-level socio-economic data, which can lead to sub-optimal. However, little is known about the agreement between individual and area-level variables. The objective was to assess the agreement between individual and area-level social risk variables in the general French population.

Methods:

We used data from the CONSTANCES general-purpose cohort, a randomly selected representative sample of French adults aged 18-69 years. Data collected include socioeconomic and demographic characteristics, behaviors, and health data. We assessed the correlation or agreement between individual and area-level variables for 4 dimensions: household annual pretax income, secondary education completion, occupational group (workers), and unemployment.

Results:

115,263 individuals were included in the study, 53% female and aged 48 years on average. The median annual household income was 42,000 Euros (USD 50,400), 73% had completed secondary education, 7% were unemployed, and 9.3% were workers. The correlation between income measured at the individual and area level was positive but moderate ($Rho = 0.20$; $p < 0.01$). Individuals having completed secondary education had a higher area-level median completion rate compared to those having a lower education level (48% versus 41%; $p < 0.01$). Unemployed individuals had a slightly higher area-level median unemployment rate compared to employed ones (11% versus 10%; $p < 0.01$). Lastly, workers had a higher area-level median probability to be a worker rate compared to other individuals ones (25% versus 18%; $p < 0.01$).

Conclusions:

In the general French population, area-level socio-economic variables are poor proxies for individual-level social risk.

Key messages:

- Area-level socio-economic data is a poor proxy for individual data.
- Researchers and policy makers should move towards individual data.

The economic burden of NCDs due to low fruit and vegetables consumption in the Russia in 2016

Dinara Mukaneeva

D Mukaneeva[1], *A Kontsevaya*[1], *Y Balanova*[1], *A Myrzamatova*[1], *M Khudyakov*[1]
[1]National Medical Research Center for Preventive Medicine, Moscow, Russia
Contact: DMukaneeva@gnicpm.ru

Introduction:

A significant risk factor for NCDs is low fruit and vegetables (F/V) consumption, which leads to economic and social costs in all countries, regardless of income level.

Aim:

To evaluate the economic burden of NCDs associated with low F/V consumption in the RF in 2016, including the direct costs and the economic losses caused by reduced productivity.

Materials and Methods:

An analytical review of the literature on the search for relative risks (RR) of morbidity and mortality from NCDs associated with low F/V consumption was carried out. Based on data on the prevalence of low F/V consumption in the RF (41.9%) and RR, the attributive risk for the population (PAR) was calculated for CVD, diabetes and several types of cancer. To assess the economic burden, the proportion of risk factor in morbidity and mortality from NCDs included in the analysis based on PAR was determined. Direct costs were calculated on the basis of tariffs for the provision of medical care in the RF in 2016 and the amount of disability benefits. Indirect costs included the loss of gross domestic product due to premature mortality and disability.

Results:

PAR of low F/V consumption in the RF in 2016 in mortality for all CVD was 5%, in morbility about 7%, in morbility of stroke - 10%. PAR of low F/V consumption in morbility of diabetes was 6%, COPD - about 5%. PAR of low F/V consumption in mortality for ovarian cancer was 27%, for kidney cancer - 20%, in morbility from 3% for stomach cancer to 40% for pancreatic cancer. The economic burden associated with low F/V consumption in the RF in 2016 amounted to about 162 billion rubles (0.19% of GDP). A significant contribution to the economic burden was made by cancer: pancreatic cancer (38.2%), colorectal cancer (21.3%), ovarian cancer (26.3%), kidney cancer (26.4%).

Conclusions:

An assessment of the economic burden will be an argument for justifying the feasibility of investing in the prevention of NCDs associated with low F/V consumption.

Key messages:

- To evaluate the economic burden of NCDs associated with low F/V consumption in the RF in 2016, including the direct costs and the economic losses caused by reduced productivity.
- The economic burden associated with low F/V consumption in the RF in 2016 amounted to about 162 billion rubles (0.19% of GDP).

Confraternal talks impact with general practitioners on the prescription for older adults

Valérie Mauillon

V Mauillon[1]
[1]Direction Regionale du Service Medical de Normandie, French National Health Insurance System, Rouen, France
Contact: valerie.mauillon@assurance-maladie.fr

Issue:

10% patients over 75 and patients aged from 66 to 75 years with a chronic disease take more than 10 concomitant drugs. Polypharmacy is a consistent risk factor of adverse drug events for elderly patients. Adverse drug reactions prevention is a national priority in view of quality of life and healthcare system costs increase.

Description:

In Normandy, since November 2015, various interventions such as confraternal talks or letters send to general practitioners (GPs) have been examined to optimize medication use in older adults. More than 16 drugs prescriptions were discussed with the family practitioner and a health insurance fund's physician-advisor. In addition, a prescription profile in elderly patients was given to this GP. Recommendations for good practices are also reminded.

Results:

10 weeks of physicians prescriptions were studied during one year (from september 2015 to september 2016). 686 general practitioners (GPs) had at least one prescription over 16 drugs and 265 GPs had at least two prescriptions over 16 drugs. 166 confraternal talks or phone calls between health insurance doctors and GPs have been leaded with a medication review. 233 letters have been sent to physicians to improve prescribing. 46% of GPs received a physician-advisor led intervention. After these interventions, prescriptions drugs number has decreased ($p < 0{,}001$) and the number of GPs having more than 16 prescriptions drugs has also decreased ($p = 0{,}27$). There is no significant difference between confraternal talks and letters. However, the physicians are more confortable with the confraternal talks to discuss their prescriptions.

Lessons:

Confraternal talks continued in 2017 with medication review and profile's delivery. A two years follow-up on these accompanying interventions will be made to optimize drugs prescriptions use for elderly patients.

Key messages:

- The physicians are more confortable with the confraternal talks to discuss their prescriptions.
- There is no significant difference between confraternal talks and letters.

Demographic forecasting of population projection in Greece: A Bayesian probabilistic study

Demetris Lamnisos

D Lamnisos[1], *K Giannakou*[1], *T Siligari*[2]
[1]Department of Health Sciences, European University Cyprus, Nicosia, Cyprus
[2]Department of Public Health, Edessa General Hospital, Edessa, Greece
Contact: D.Lamnisos@euc.ac.cy

Background:

Demographic aging is an emerging issue in Greece, characterized by low fertility and increased life expectancy. Undoubtedly, demographic aging is a challenge for public health not only due to the financing of public pensions, but also for the increasing utilization of health care.

Methods:

The total fertility rate and life expectancy at birth are projected probabilistically using Bayesian hierarchical models and United Nations population data for Greece from the period of 1950 to 2015. These are then converted to age-specific mortality rates and combined with a cohort component projection model. This yields probabilistic projections of total population by sex and age groups, total fertility rate (TFR), female and male life expectancies at birth and potential support ratio PSR (persons aged 20-64 per person 65+) by the year 2100.

Results:

The total population in Greece in 1950 was around 7.5 million, increasing to 11 million based on the 2011 population census but is projected to decline to 7.5 million at 2100. TFR has followed a strong downward trend with 1.4 children per woman in 2005-2010 and is projected to have a slight increase to 1.6 and 1.8 children per woman for 2050 and 2100 with all values being below the replacement-level fertility. Life expectancy is expected to increase to 84 years for men and 88 years for women in 2050, and 90 years for men and 94 years for women in 2100. PSR is expected to decline dramatically from 3 in 2011 to approximately 1.5 in 2050 and 2100.

Conclusions:

Over the years, Greece has lost its youthful structure and has acquired the characteristics of an aging population, reflecting the population distribution of Western countries. Demographic aging is harmful for the economic growth, the social security system, the social assistance, and it is closely linked to national defense and public health. A long-term multidimensional program is recommended to confront the demographic issue based on the previous international experience.

Key messages:

- Total fertility rate will be below replacement level and potential support ratio will decline dramatically.
- A long-term multidimensional program needs to be developed to address the demographic aging.

Availability and drug lag of new medicines in South Korea

Kyung-Bok Son

K Son[1]
[1]College of Pharmacy, Ewha Womans University, Seoul, South Korea
Contact: sonkyungbok@gmail.com

Introduction:

This study aims to capture the availability of new medicines, to measure drug lags for new medicines, and to demonstrate various factors affecting timely availability of new medicines in Korean market.

Methods:

We construct two models for the analysis; logistic and Cox model. First, we provide the logistic regression to analyze the availability of new medicines in Korean market. Second, we are interested in the timely availability of new medicines in Korea. Therefore, we calculated the drug lag between the United States and South Korea, and applied an event history model for a statistical estimation.

Results:

There have been 160 NDAs approved by the FDA in the United States between 2007 and 2015. Among 160 new drugs approved in the United States during the study period, 112 NDAs (70%) were also approved by the MFDS in Korea, while 48 new drugs (30%) are not currently available in the Korean market. In addition, we are interested in the order of timing for market approval for 112 NDAs that approved in both countries. Not surprisingly, 95 NDAs (85%) were approved in the United States, and then approved in Korea, while 17 NDAs (15%) were approved in Korea, and then approved in the United States.

Conclusions:

Compared to the United States, a striking drug lag was observed in Korea. For the new drugs approved between 2007 and 2015, the median approval lag ranged from 1.72 years in 2013 to 5.84 years in 2007. Presence of the manufacturers in Korea and medicines belonging to the antineoplastic agents were not only positively associated with the availability in Korea, but also accelerated the time to approval in Korea compared to the reference.

Key messages:

- Compared to the United States, a striking drug lag was observed in Korea.
- Presence of the manufacturers in Korea were not only positively associated with the availability in Korea, but also accelerated the time to approval in Korea.

Assessment of State of Health and Healthcare Expenditure by Single-Person Households

Aviad Tur-Sinai

A Tur-Sinai[1], *R Magnezi*[2], *H Grinvald-Fogel*[2]
[1]Health Systems Management, The Max Stern Yezreel Valley College, Yezreel Valley, Israel

[2]Management, Bar-Ilan University, Ramat Gan, Israel
Contact: avts2309@netvision.net.il

Background:

The latest statistics on household size in the EU show that in 2017 around one third of households in the EU comprised single adults without children. The study documents a direct relationship between individuals' health and patterns of healthcare expenditure by isolating single-person households and creating a new reference group in which household healthcare expenditure is based on one person's expenditure patterns in accordance with his or her own state of health.

Methods:

The study matched two surveys using Propensity Score Matching based on single-person household, age, and gender. Structural Equation Modeling (SEM) explores paths of relation between the population's income and socio-economic level and its health self-assessment and expenditure.

Results:

Single-person households' health expenditure increases with age and the differences in most expenditure categories are significant. The current study looks into the direct and indirect effects of income, gender, and SES on health insurance and other out-of-pocket health expenses among single-person households. A direct link exists between income, gender, and socioeconomic status (SES) and several aspects of health expenditure, depending on the specific age group. The indirect effects are attested via health status assessment, in which a negative correlation is found between self-assessed health status and various health-expenditure categories.

Conclusions:

The last-mentioned result may support the general perception that single-person households who feel that they are doing better than their near-equals enjoy better health. This line of inquiry yields a better examination of how a single-person household's state of health affects expenditure patterns without assuming ab initio that expenditure patterns attest to state of health.

Key messages:

- Healthcare system and policymakers have to be mindful of the profile of single-person households and should ensure to examine these households' patterns of healthcare expenditure as a function of age.
- Policymakers should seek alternative sources of funding for the single-person households' health-insurance outlays and should examine alternative ways of restraining their expenditure on dental care.

The social and economic benefit of health literacy interventions in the WHO EURO region

Mariana Dyakova

A Stielke[1], M Dyakova[1], K Ashton[1], T van Dam[1,2]
[1]WHO CC on Investment for Health & Well-being, Public Health Wales NHS Trust, Cardiff, UK
[2]Faculty of Health, Medicine and Life Sciences, Maastricht University, Maastricht, Netherlands
Contact: mariana.dyakova@wales.nhs.uk

Background:

Health literacy (HL) allows people to make informed decisions regarding their health, enabling them to understand health promotion activities and to self-manage their disease or complication without requiring support from healthcare services. HL has the potential to support sustainability in health systems by decreasing healthcare spendings stemming from lowered disease occurrence and progression, it can also impact on the rest of peoples' lives and their surroundings by allowing them to be more independent. This study researched the evidence for return on investment and the social return on investment for health literacy interventions within the WHO EURO region.

Methods:

A narrative literature review on published peer-reviewed reviews and grey literature was conducted by use of keywords and MeSH terms. Google, Google Scholar and PubMed were used find literature. The search on PubMed was restricted to reviews, published within the last 10 years (2009-2019), in English.

Results:

In total, 450 publications were screened 12 publications that analysed the economic or social aspect of HL interventions were identified. Five discussed the cost-effectiveness of health literacy, three the return on investment (ROI) and the remaining three the social return on investment (SROI) of HL. Types of HL interventions ranged from health promotion campaigns, web-based HL programs, prevention systems to education-based interventions. Cost-effectiveness differed between studies and fields. Evidence for ROI was found, the return ratios ranged from 0.62 to 27.4. Findings show SROI between 4.41 and 7.25, indicating additional value of social benefit next to improved health.

Conclusions:

A link between cost-effectiveness and HL interventions was established and ROI and SROI showed positive ratios. Further research is required in order to investigate whether HL interventions consistently achieve a positive returns.

Key messages:

- A link between health literacy interventions and positive investment returns has been established.
- Health literacy interventions show potential for sustainable development of health systems.

Capturing the social value and return on investment of public health services and interventions

Mariana Dyakova

K Ashton[1], A Stielke[1], M Dyakova[1]
[1]WHO CC on Investment for Health and Well-being, Public Health Wales NHS Trust, Cardiff, UK
Contact: mariana.dyakova@wales.nhs.uk

The need for investment in health and well-being to achieve sustainable development and inclusive economic growth is stronger than ever in the face of multiple adversities. Making the case for investing in public health is essential. The social, economic and environmental value of public health programmes has to be embedded in every organisational balance sheet in order to progress national and international commitments; and to enable sustainable policy and action for the benefit of people, communities and societies.

The WHO Collaborating Centre on Investment for Health and Well-being at Public Health Wales has developed a programme of work to assess the (social)return on investment of services and interventions. This involves looking at specific health and well-being outcomes, and estimating the wider social, economic and environmental value of the organisation and its various health protection and health improvement programmes. Specific health economics methods used will be Social/Return on Investment and Social/Cost-Benefit Analysis. The programme will generate an 'extended balance sheet', including estimates of health and well-being outcomes and monetarising the social and environmental value. This will result in establishing the holistic economic value of Public Health Wales. Specific outputs are: a comprehensive costing model to capture input; outcome and impact maps; capturing the value of public health programmes in terms of health and well-being, as well as social, economic and environmental outcomes. Finally, a generalised framework for other similar organisations will be developed.

This innovative programme aims to measure the social, economic and environmental value of Public Health Wales as a national public health institute. The developed framework can be used by other organisations across Europe to inform and guide their efforts to capture the wider social value, involve key stakeholders from the outset and achieve sustainable financing in the long run.

Key messages:

- Making the case for investing in public health by illustrating its social, economic and environmental value is vital.

- Social Return on Investment is an innovative and useful method to estimate the wider value of public health interventions.

Experience of clinical nursing guidelines development in Kazakhstan

Vitaliy Koikov

A Umbetzhanova[1,2], *Zh Bekbergenova*[1,2], *V Koikov*[2], *Z Baigozhina*[2], *D Zhunussova*[1], *G Kabdullina*[2], *A Abdrakhmanova*[2]
[1]NCJSC ''Astana Medical University'', Astana, Kazakhstan
[2]RSE on the REM, Astana, Kazakhstan
Contact: vitaliy.koikov@gmail.com

Issue/problem:

Since 2019, Kazakhstan has been implementing a project to develop standards for nursing services. The aim of project is support of practical nurses with the latest available evidence via development of clinical nursing guidelines (CPG) as well as standard operational procedures (SOP), sustainable development of this area.

Description of the problem:

As part of reforming the system of nursing education in Kazakhstan, applied baccalaureate for nurses was introduced. Shortcomings of current nursing education, the introduction of digitalization and e-health, poor quality of medical services, justified need of standardization. Within the framework of the project, development groups including nurses and medical specialists were organized. The following priority topics were selected: management of diabetes, asthma, CHF, prevention of CVD. Development group uses a guide for adaptation which was prepared by project international partners from Finland. Three trainings were conducted for nursing professionals. These trainings step by step provide comprehensive knowledge on adaptation process. recommendations to local conditions.

Results:

The main outcome of the joint work is the training of a nursing research committee, who will be responsible for sustainable development of this direction. The second result is guidelines for nurses, which are very demanded in the field. The third outcome is reflexing and gaining experience in overcoming barriers for further work.

Lessons:

Adaptation of CPG is preferred approach for countries with a low level of socio-economic development because of less resource, time consuming. The adaptation process requires work commitment, a sufficient level of English proficiency, respect of authorship, but taking into account local conditions.

Key messages:

- Adaptation of nursing CPGs is an important part of standardization of medical services in order to improve the quality of medical care.
- Thorough planning of the process, training of development group will allow overcome barriers to implementation.

Economic burden of main Noncommunicable diseases in the Russian Federation in 2016

Azaliia Myrzamatova

A Kontsevaya[1], *Y Balanova*[1], *M Khudyakov*[1], *A Myrzamatova*[1], *D Mukaneeva*[1], *I Sapunova*[1]
[1]1, National Medical Research Center for Preventive Medicine, Moscow, Russia
Contact: azaliya89@list.ru

Aim:

To estimate the economic burden of noncommunicable diseases (NCDs) in the Russian Federation (RF) in 2016, including the direct costs and the economic losses caused by reduced productivity.

Material and **Methods:**

We included 4 diseases: cardiovascular, type 2 diabetes, cancer and chronic pulmonary disease (COPD). We used the official statistics data collected by Ministry of health on the number of patients, health care resources utilization (hospitalizations, emergency visits, outpatients' visits). The costs of health care were obtained from health insurance fund. Directs nonmedical costs included disabilitypayments, calculated based on the number of disabled persons from each group and by the amount of the disability allowance. Indirect costs (economic losses) included decreased productivity due to premature mortality and disability. The potential years of life lost (PYLL) were calculated using the number of life years lost due todeath and disability due to NCDs before 70 years. Human capital approach was used, and calculation were based on the GDP per person.

Results:

Number of PYLL due to premature death from NCDs was estimated to be 8,0 million years. Economic burden because of NCDs in 2016 in the RF reached 3,3 trillion (45.9 billion €), which is equivalent of 3.9% of GDP for this year. Direct costs were responsible only for 13% of losses, indirect costs for 87% of the total burden. CVD were responsible for 81,4% of burden, cancer – for 7,1%, diabetes - 6,5% and COPD for 5,0%.

Conclusions:

The economic burden because of NCDs in the RF in 2016 was 3.3 trillion (3.9% of GDP). Such the significant economic burden and absence of positive dynamics is a strong argument for increasing investments in the prevention and treatment of NCDs.

Key messages:

- Number of PYLL due to premature death from NCDs was estimated to be 8,0 million years.
- Economic burden because of NCDs in 2016 in the RF reached 3,3 trillion (45.9 billion €), which is equivalent of 3.9% of GDP for this year.

Development of health management system with recording daily living habits and body compositions

Takeo Shibata

T Shibata[1], *K Sata*[2], *T Oroguchi*[2], *N Ishii*[1]
[1]Department of Health Management, Tokai University, Kanagawa, Japan
[2]Lifecare Center, Tokai University, Kanagawa, Japan
Contact: takeo.shibata10@gmail.com

It is difficult for university students to maintain their health. Department of health management was opened at April 2018 in Tokai university, Japan. About two hundred students entered it last year. Health management system was developed to maintain their health through the college life. The system is named THINKss (Tokai Health INtelligence Knowledge Support System). The number of registered students increased about four hundred this year. Every student can record their daily physical and mental conditions, meal photos with the time, body temperature, blood pressure, bone density, body compositions on their smartphone. If they use activity trackers with a wrist-based heart rate sensor (Garmin co. ltd.), their daily activities and sleeping status are corrected through API automatically. The weather information around university is also recorded everyday. Every student can browse own measurements on their smartphones. Because physical status includes cold symptoms (sneeze, throat pain, cough, fatigue, articular pain, muscle pain, chill, and body temperature), the system can recommend visiting a clinic. Because three meal photos are shown alongside, the balance of the meals is known. It may improve their meals. Because the activity tracker records advanced sleeping status (rem, light, deep, and moving), the relationships between mental conditions and sleeping status should be analyzed. Our previous study for common workers showed that mental status related with sleeping status, taking lunch of convenience-store, standard deviation of time of taking lunch, and oversensitivity to noise. Relationships between body composition changes and the lifestyles should be analyzed for university students. Some alert logics for body composition changes and exacerbating mental conditions may be provided based on the evidences from cumulative data of the health management system. These evidence-based alerts will contribute to maintain student's health through a college life.

Key messages:

- Health management system was developed to maintain student's health through the college life.
- Evidence-based alerts will contribute to maintain student's health through a college life.

Public expenditure on health promotion and prevention interventions in Austria in 2016

Brigitte Piso

K Antony[1], *B Fröschl*[1], *S Ivansits*[1], *S Gaiswinkler*[1], *A Laschkolnig*[1]
[1]Gesundheit Österreich GmbH, Austrian Public Health Institute, Vienna, Austria
Contact: Brigitte.Piso@goeg.at

Issue/problem:

Government and social insurance-funded health promotion and prevention interventions in Austria are surveyed on an irregular basis. Comprehensive data on government expenditures, categorized according to financial providers and/or intervention types had not been published since 2012.

Description of the problem:

In accordance with Austrias current federal target contract, the survey is intended to support the targeted use of funds in the fields of health promotion and prevention by providing timely and detailed information on public spending in these areas.

Results:

In 2016, the public sector spent 2,441.3 million euros on health promotion and prevention, which corresponds to 280.6 euros per capita (of the Austrian population). Additionally, administrative bodies reported staff-related costs, which could not be monetarily assessed for all administrative levels.

70 per cent of the expenditure on health promotion and prevention incurred by public institutions in Austria went towards tertiary prevention. The shares for primary and secondary prevention are 13.5 and 13.2 per cent respectively, the remaining funds were spent on health promotion and capacity building (3.4 per cent).

Lessons:

The collection and coordination effort is considerable for data reporters and study authors, still more frequent collection facilitates data reporting and quality.

An overview of the data is still not available at the administrative level of the countries (Länder), this could contribute to informed decisions.

Key messages:

- Expenditures on health promotion and primary prevention show high growth rates for the period 2012-2016 (+21.3%) reflecting the continuing social importance that this topic has gained in recent years.
- An allocation of funds to the areas prioritized in the Austrian health promotion strategy 2013-2016 is evident for at least three topic areas.

Balanced Scorecard for performance assessment in healthcare settings: a review of literature

Pasquale Cacciatore

P Cacciatore[1], *P Kannengiesser*[1], *E Carini*[1], *A Di Pilla*[1], *AM Pezzullo*[1], *I Hoxhaj*[1], *I Gabutti*[3], *A Cicchetti*[3], *S Boccia*[1,2], *ML Specchia*[1,2]
[1]Sezione di Igiene, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy
[3]Alta scuola di Economia e Management dei Sistemi Sanitari (A, Università Cattolica del Sacro Cuore, Rome, Italy
Contact: pasqualecacciatore@gmail.com

Background:

The Balanced-Scorecard (BSC) is a management tool developed in the early 1990s to balance the impact of financial and non-financial parameters and analyse the organisational performance in private companies according to four determinants. The original BSC has spread to different sectors in the last decades, including healthcare services, in numerous amended versions. The aim of our project was to identify potential indicators of BSC for performance evaluation in general hospitals.

Methods:

We performed a systematic review of literature on Pubmed and Web of Science using the search string ''balanced scorecard AND healthcare AND indicators''. We found 102 papers; 80 papers were removed for irrelevance, absence of full text or performance indicators. We only considered articles that followed the classic structure of BSC (Customer, Internal Processes, Financial, and Learning and Growth). The indicators listed in them were classified according to the four determinants of organisational performance.

Results:

Eight articles out of 22 followed the classic structure of the BSC. The most represented category was Internal Processes (59 indicators), followed by Learning and Growth (52), Customer (40) and Financial (33). The number of common/overlapping indicators was low (5 for Internal Processes and 4 for the three other categories).

Conclusions:

While BSC has spread to different settings, the list of indicators used in the classic four determinants for performance evaluation is heterogeneous. While common points can be identified between indicators, our review highlighted that every BSC is developed in a unique way which makes it difficult to identify a general framework adaptable to different hospital settings.

Key messages:

- The use of the Balanced Scorecard as management tool has spread to healthcare settings in the last decade.
- Indicators in BSC for healthcare settings are heterogeneous and only a limited number follow the standard structure of BSC.

Health insurance literacy assessment tools: A systematic review

Ana Cecilia Quiroga Gutierrez

AC Quiroga Gutierrez[1]
[1]Department of Health Sciences and Health Policy, University of Lucerne, Luzern, Switzerland
Contact: ana.quiroga@unilu.ch

Background:

Health insurance literacy (HIL), defined as the ability to seek, obtain, understand health insurance, and use it once enrolled, is a concept that has only recently started to gain increasing attention. HIL is likely to influence individual's usage of health care services and subsequent outcomes. Yet, little is known about its distribution and its associations with health(-related) outcomes, due to the fragmented nature of the field and assessment tools. The objectives of this study are to (1) summarize information on current assessment tools for HIL and related constructs, (2) describe conceptual dimensions assessed, and (3) describe psychometric properties of found tools.

Methods:

A systematic literature review was performed using various databases (e.g. PubMed, CINAHL, Econlit), identifying literature that provided a description of tools assessing HIL and related constructs (e.g. health insurance knowledge). In the following, two independent reviewers will screen abstracts and studies included for full-evaluation. The COnsensus-based Standards for the selection of health Measurement Instruments (COSMIN) will be used to assess quality of included studies and measures.

Results:

Information on found tools will be summarized, including information on type of measure (e.g. objective or self-reported assessment), items and scales, scoring, target population, assessed domains, correlation with other measures. Preliminary results show large variations across tools that have been used to assess HIL and related constructs, with the majority not being rigorously validated.

Conclusions:

The resulting summary of this study is intended to work as a basis for the conceptualization of HIL and development and validation of assessment tools, with the aim to homogenize and improve research in the field of HIL.

Key messages:

- Current knowledge on HIL distribution and its association with health(-related) outcomes is fragmented due to lack of consistency on HIL conceptualization and assessment.
- This systematic literature review aims to summarize information on current HIL assessment tools to inform the development and validation of HIL assessment tools.

Measuring inequity in using routinely collected data in an emergency setting: a systematic review

Kevin Morisod

K Morisod[1], *X Luta*[2], *J Marti*[2], *T Brauchli*[3], *J Spycher*[2], *P Bodenmann*[1]
[1]Departement of Vulnerabilities and Social Medicine, Center for Primary Care and Public Health, University of Lausanne, Lausanne, Switzerland
[2]Health Care Evaluation Unit, Center for Primary Care and Public Health, University of Lausanne, Lausanne, Switzerland
[3]Unit for Public Health Documentation and Data Management, Center for Primary Care and Public Health, University of Lausanne, Lausanne, Switzerland
Contact: kevin.morisod@unil.ch

Background:

The international literature has highlighted many potential challenges in terms of inequitable access to care. In the last few years, health equity is becoming an increasingly important issue for policymakers, particularly in developed countries. The aim of this systematic review was to find how equity is measured and to identify some of its determinants.

Methods:

We conducted a systematic review on all major databases (Medline Ovid SP, PubMed, Embase and Web of Science), following the PRISMA guidelines. We included published observational studies that reported on health equity and using administrative data, with a focus on emergency and unplanned hospital care. Study selection and data extraction were conducted independently and compared by two reviewers.

Results:

In total, 223 records were screened and 39 articles met the inclusion criteria. Studies come from the United States (US) (23), United Kingdom (6), Canada (4), Australia (2) and some European countries (4). To measure health inequity, most of the studies used at least one of these 4 indicators: hospitalisations for chronic ambulatory care sensitive conditions (or preventable hospitalisations), emergency hospitalisation rate, readmissions or mortality. The most relevant health equity determinants concerned race/ethnicity (19), poverty (17), health insurance coverage (17) and gender (16). Race/ethnicity and gender are important determinants of inequities. Concerning poverty, despite the use of heterogeneous indicators, most of studies showed a socio-economic gradient of access to care. Health insurance coverage was often used but with conflicting results.

Conclusions:

The use of indicators linking primary, emergency and hospital care seems to be particularly relevant to measure health inequity. Race/ethinicity, gender and socio-economic status are clear determinants of inequitable access to care. More studies are needed to explain and analyse the determinants of health equity.

Key messages:

- Health equity remains a major issue even for high-income countries health care system.
- Quantitative data about health equity still are needed to support policymaker's recommendation.

The endless story of copayment insurance in Slovenia - is it necessary?

Tit Albreht

T Albreht[1]
[1]Centre for Health Care, National Institute of Public Health, Ljubljana, Slovenia
Contact: tit.albreht@nijz.si

Issue/problem:

Slovenia maintains its specific type of voluntary health insurance, which is actually a complementary health insurance (CHI). The main criticism against it was in its regressivity as the premium is flat-rate, equal for all insured.

Description of the problem:

The share of CHE in total health expenditure (THE) has been growing until recently and now represents roughly 15% of THE. Even if remains an important source of financing, there are still pressures to abolish it. The present government again set its abolishment as one of the priorities. As much as it is regressive in essence, some of the negative effects of regresivity were offset by the State stepping in by paying the copayments for those citizens who are in need of social cash benefits.

Results:

CHI contributed to the stability of the funding of Slovenia's health care system. The space for the increases has become very limited as it covers up to 90% of the price in the case of many medicines, several dental procedures, rehabilitation and similar services. That means that additional increases with offsets to CHI from the compulsory health insurance are not possible. When the need for these emerges, CHI will not be a solution anymore, which means that an alternative needs to be found. From the several options we explored, the most probable is a gradual increase in the compulsory health insurance contributions.

Conclusions:

CHI in Slovenia remains a controversial topic although its criticism has lost edge recently. Partly, this was due to the clear demonstration of its contribution to the stabilisation of the THE in the times of austerity. On the other hand, the mass of money in the compulsory health insurance has increased due to the economic growth and the need to offset costs to CHI was reduced. But, as there is little space left for such actions with the new crisis, a clear scenario on how to address the need for additional funds in the health care system is needed.

Key messages:

- Complementary health insurance contributed to the stability of health expenditure during crisis.
- The main alternative to CHI is its full inclusion into the compulsory health insurance.

The satisfaction of the new competencies and roles of nurses in Kazakhstan

Vitaliy Koikov

Z Bekbergenova[1], *Z Baigozhina*[2], *A Umbetzhanova*[1,2], *G Kabdullina*[2], *A Abdrakhmanova*[2], *V Koikov*[2]
[1]NCJSC ''Astana Medical University'', Astana, Kazakhstan
[2]RSE on the REM, Astana, Kazakhstan
Contact: vitaliy.koikov@gmail.com

Background:

When interviewing nursing specialists of the Republic of Kazakhstan (RK) about the level of satisfaction with the prospects of the profession with the participation of 9039 nurses, 71% of whom believe that nurses should be given special status. To study the satisfaction of the new competencies and roles of nurses in the framework of the reform of the nursing service conducted a survey of employers

Methods:

The cross-sectional study in 1417 of employers participated, of which 11% were senior doctors, 26% deputy chief physicians, 50% of heads of departments, 13% others.

Results:

Analysis of the survey results showed the following:

- more than 70% of employers have a positive attitude towards nursing service reforms. According to 48% of employers, the functionality of nurses is expanded. 54% of nurses fully cope with new functional responsibilities. 44% of respondents say that with the expansion of the functionality of nurses, doctors have more time to perform more complex skilled work. According to 44% of employers, nurses should delegate the primary reception and examination of the patient, 42% setting the primary diagnosis, 33% deciphering the results of laboratory and instrumental studies, 21% independent visiting the patient at home, 8% active prenatal and postnatal patronage, 17% rendering premedical and emergency medical care. 62% of employers consider it appropriate to introduce the practice of joint training of doctors and nurses and fully support the increase in the independence of the nursing service.

Conclusions:

In general, employers support the reform of nursing, are satisfied with the new competencies of nurses and have a positive attitude towards increasing their independence.

Key messages:

- It is necessary to improve basic training programs in medical colleges and to implement effective advanced training programs for working nurses.
- It is advisable to practice the introduction of co-education for doctors and nurses - the practice of inter-professional teams specialists.

Calculation of road accessibility for the rural population in the Shikoku Island of Japan using GIS

Rina Katayama

R Katayama[1], *M Defratti*[2], *T Inoue*[1], *L Peters*[2]
[1]Aoyama Gakuin University, Tokyo, Japan
[2]Environmental Systems Research Institute Inc., CA, USA
Contact: rkatayama5@gmail.com

Background:

The United Nations has defined 17 Sustainable Development Goals as a blueprint for helping ensure the health and well-being of our world by 2030. The global goals address challenges we face including poverty, inequality, climate, environmental, peace and prosperity. The goals each have targets and indicators to help measure success. Indicator #9.1.1 is defined as "Proportion of the rural population who live within 2 km of an all-season road", which can aid in understanding multiple areas of human well-being including access to food, health care, education and in support of economic development. By understanding access to infrastructure, we can focus on affordable and equitable access for all. We focused on the Shikoku Island of Japan and calculated indicator #9.1.1 using spatial analysis.

Methods:

We utilized data from three sources listed below. Cho-cho-moku boundaries population data from the Esri Japan corporation. Metropolitan Employment Area data from the Center for Spatial Information Science at the University of Tokyo. Emergency transport road data from the MLIT of Japan. We conducted proximity analysis with Geographic Information System (GIS) and estimated population of the target area using the area ratio of the target area to the original Cho-cho-moku area.

Results:

The percentage of the rural population who live within 2 km of an all-season road is 79.5% and those who have no access to an all-season road in the Shikoku Island is 20.5%.

Conclusions:

We found the proportion of the rural population that cannot reach an all-season road by calculating indicator #9.1.1. 20.5% of the rural population in the Shikoku Island of Japan may have difficulties accessing essential services such as health care, education, food, and may have difficulties with economic development. By understanding accessibility to road infrastructure, we were able to identify areas at risk for access. We can work towards creating more equitable access in a next step.

Key messages:

- By conducting spatial analysis with GIS, we can identify areas at risk for access to infrastructure.
- we can focus on creating more affordable and equitable access for all by understanding access to infrastructure such as health care, education and food.

How the Euripid collaboration contributes to affordability of medicinal products

Claudia Habl

C Habl[1]
[1]Gesundheit Österreich GmbH, Austrian National Public Health Institution, Vienna, Austria
Contact: claudia.habl@goeg.at

Issue:

National authorities for pricing and reimbursement of medicinal products need up-to-date, easy accessible and unbiased information on the availability and prices of medicinal products in their fellow countries. Such information is needed for informed decision making, very often by countries who have an element of external price referencing (EPR) integrated into their national drug policy. EURIPID (www.euripid.eu) is a voluntary, non-profit collaboration between mainly European countries on building up and maintaining a database with information on national prices of medicinal products. It makes prices of price regulated medicinal products more transparent via an on-line accessible, comprehensive, reliable, and easy-to-use database.

Challenges of the database are

- to bring the numerous products of the currently 28 countries to a common platform in a standardised format and to translate the products and their presentation into English language (especially those who have no centralised EMA marketing authorisation),
- to present four comparable price types (e.g., to which Danish price type does the British NHS price compare),
- to calculate or approximate missing price types,
- to provide additional information allowing to indicate the real price of the product rather than its list price.

Results and lessons learned:

The participating countries agreed by online voting to share information on Managed Entry Agreements (or related arrangements) and provide volume information for the reimbursed products in the database. The countries also agreed to provide background information on the national pricing system. In the last EU period the Collaboration developed a Technical Guidance Document on External Price Referencing that regulates in 12 principles the "Do's and Don'ts of ERP".

In the new grant period a stakeholder dialogue platform will be established to strengthening the cooperation within the EU in the field of pricing of medicinal products.

Key messages:

- The Euripid database is a valuable tool that is aiding countries to perform price comparisons for ERP or price monitoring for medicinal products in a standardised format.
- ERP is still widely used in Europe. The new activities of Euripid (e.g., a website offering information to the public), will contribute to a fair use of ERP and thus improve national decision making.

DN Health workforce development and research

A new health professional profile in Switzerland: the county practitioner?

Sandrine Motamed

S Motamed[1]
[1]Institute of Global Health, Genève, Switzerland
Contact: motamed@bluewin.ch

In the vogue to provide Geneva with a health and social system with intermediate structures between practitioners and hospitals, many proposals have been made. All have the characteristic of omitting the fact that the general physician, central element of the system, could be set to one side. A family doctor remains a clinician, and is manager of the disease. The proposals lack what we call the community dimension and do not approach citizens from the point of view of their health.

Some components of this new professional profile are at the individual level and already form part of the primary care physician's activity. Others, on the other hand, are akin to collective or community-based interventions, so are not generally included in the primary care practice. Thus, in collaboration with the central structures of the canton and the authorities, activities such as medicine at school or nursing home, epidemiological surveillance, participation in development projects and actions dealing with the environment, etc., could represent the community part of this new practice.

In view of this, the concept of 'county practitioner' was implemented in the framework of a global project emanating from the authorities of a county of the state of Geneva in Switzerland, which aimed to develop social links, well-being and health through the complete restructuring of the village center. Other projects, in other municipalities, were inspired by this first experience, although the 'country practitioner' is currently limited to a role of "health adviser". Several examples could be presented. The conditions for bringing into being such a profile are numerous: the drafting of specifications, the political will and the benevolence of fellow practitioners fearing a loss of power. Once again, the community doctor does not replace the attending physician, he completes his action mainly in the field of community health.

Key messages:

- The concept of 'county practitioner' was implemented in the framework of a global project emanating from the authorities of a county of the state of Geneva.
- The conditions for implementing such a profile are numerous.

Social aspects of occupational diseases in clothing industry in Bulgaria

Irena Stoilova

I Stoilova[1]*, S Georgieva*[2]*, M Kamburova*[2]*, P Kostadinova*[3]
[1]Department of Hygiene, Medical Ecology and Occupational Dise, Medical University of Pleven, Pleven, Bulgaria
[2]Department of Public Health Sciences, Medical University of Pleven, Pleven, Bulgaria
[3]Regional Health Insurance Fund of Pleven, Pleven, Bulgaria
Contact: irena.stoilova444@abv.bg

Background:

The clothing industry is traditionally well developed branch of industry in Bulgaria Harmful factors of manufacture are forced posture, monotonous work, noise, vibration, poisons etc. At the beginning of 2016, the persons directly employed in the sector add up to 92 000, representing 6% of the employees in Bulgaria. An impairment of musculoskeletal and peripheral nervous system is frequent among these people in relation with the exposure of their professional experience. The aim of the study is to observe the influence of occupational diseases in clothing industry on social and emotional wellbeing of the employees.

Methods:

For the purposes of the study, 103 persons employed in clothing industry, with impairments of the musculoskeletal system and the peripheral nervous system, were investigated. They were admitted to the Department of Occupational Diseases, of the University Hospital in Pleven during the period 2014-2017. Data were collected by interview, documents review and clinical examination.

Results:

Analysis of the results revealed a statistically significant inverse association between performance of daily life activities and length of exposure of patients ($p < 0.05$). This means that increasing length of exposure restrict the abilities of the investigated persons to perform daily life activities. About 62% of the respondents are often and long standing patients, with more than 4 cases of hospitalization and over 30 days of disability per year. In 68% of the subjects the average duration of one illness exceeds 10 days. Long period of disability affect their income, working position and family relationships. More than a half of people surveyed (56%) cannot afford the recommended rehabilitation which retards the process of recovering. All these facts affect their mood and health self-esteem.

Concussion:

Occupational diseases in clothing industry affect quality of life, social and professional performance of the employees.

Key messages:

- In clothing industry many risk factors affect workers' health. There is a significant association between length of occupational experience in this branch and social aspects of occupational diseases.
- Occupational diseases in clothing industry affect capability of work and daily routines of employees. They have been associated with long and expensive period treatment and rehabilitation.

From pillars of postgraduate education towards motivated and competent public health workforce

Nino Chikhladze

N Chikhladze[1]*, N Pitskhelauri*[1]
[1]Faculty of Medicine, Tbilisi State University, Tbilisi, Georgia
Contact: chikhladze.nino@gmail.com

Background:

Motivation and effective supervision are key factors in postgraduate Public Health Education. On the one hand motivation represents a power that derives and then steers students' activities in order to achieve their objectives; on the other hand, supervision practices can significantly influence the behavior of students, from encouraging students to endeavor future goals to letting them lose the motivation to continue the study. The aim of this research is to study motivation of PhD students and to explore the supervision practices at the Department of Public Health.

Methods:

A Special questionnaire has been developed and quantitative method has been used for this study. The questionnaires were distributed to all PhD students at TSU Faculty of Medicine.

Results:

A total of 79 completed questionnaires have been used for analyses (response rate 52,6%). The study found that around 90% of the PhD students are generally satisfied with existing supervisory experiences. 87% of respondents mentioned that they have regular meetings with their supervisors and the importance of these meetings are evaluated as important or very important. The study also found that PhD students are more influenced by intrinsic motives and students place priority emphasis on the interest in scientific research and continuing learning experience. At the same time the greatest incentive for deciding to become a PhD student is the possibility of acquiring experience within international partnerships, among them short- or long-term mobility in the

Framework of DIKU funded project „Georgian-Norwegian Collaborative in Public Health'' and NIH funded project, ICREATE - Increasing Capacity in Research in Eastern Europe''.

Conclusions:

The study has provided the insights into supervision practices and PhD students' motivation. Survey has raised some emerging issues, which are inclined to be improved in order to strengthen the postgraduate Public Health Education.

Key messages:

- The research emphasizes the importance of evaluating the motivation and supervision practices in postgraduate public health education for strengthen the public health graduates and workforce.
- The research highlights the impacts of international collaborative partnerships in transitional countries.

Evaluation of chronic disease follow-up training of family physicians in primary care units

Erkan Pehlivan

B Buzgan[1], *B Mete*[2], *E Pehlivan*[3]
[1]Provincial Health Directorate, Mother and Child Department, Bingöl, Turkey
[2]Provincial Health Directorate, Public Health Department, Bingöl, Turkey
[3]Inonu University, School of Medicine, Battalgazi, Malatya, Turkey
Contact: erkan.pehlivan@inonu.edu.tr

Background:

Chronic diseases are a major cause of morbidity and mortality due to late diagnosis and insufficient treatment. This study deals with the training on chronic diseases organized by the Ministry of Health in the provinces. The aim of this study was to measure the effectiveness of training programs for family physicians in a province.

Methods:

This semi experimental study was carried out during the training held in Bingöl that is eastern city of Turkey, on 22-26 October 2018 and 19-20 December 2018. The universe of the study consisted of family physicians working in the province. Of the 90 family physicians working in the province, 75 participated in the study. The training was conducted by the researchers and (before-after) 16-question test to the participants were used. The trainings cover the sub-heading Cardiovascular Risk Assessment and Diagnosis and Treatment of Hypertension. The family physicians were divided into 7 groups and were given 7-hour training. SPSS 25 program was used to analyze the data. In the analysis of data, Wilcoxon test, Cochran's Q test and Bayesian approach samples t test were used.

Results:

The average number of correct before training was 7.33 (min: 2 - max: 13), after training 12.64 (min: 7- max: 16; $p < 0.001$). After the training, participants' correct answers to 15 questions increased ($p < 0.001$). Increase rate is 71%. Bayesian factor was found to be < 0.001 according to the results of Bayesian approach t test. There is definite evidence against the H0 hypothesis. According to the results of this quasi-experimental study, training is very effective.

Conclusions:

In this study, it was shown that the education of the family physicians about the chronic diseases of the Ministry of Health is effective in increasing the knowledge level of family physicians.

Key messages:

- The training of the family physicians in charge of the primary health care is important.
- This study showed that education is very effective accorging to the pre-training.

Looking for bridge engineering: the role of an information officer in 'sanitary service'

Marion Defaut

M Defaut[1], *A Sizaret*[1], *MF Manca*[2]
[1]Information & Resource Centre, IREPS BFC, Dijon, France
[2]CHU, Dijon, France
Contact: m.defaut@ireps-bfc.org

Background:

Launched in 2018, 'sanitary service' aims at training all future health professionals in prevention issues, through elaborating concrete projects designed for population identified as priority. It responds to the first axe of the National Health Strategy, which is to develop a prevention and health promotion policy. In our region, about 430 actions have been implemented by 2200 students, in interdisciplinary teams.

Objectives:

From this context occurred a reflection on how a documentary product can be used as a bridge between various health disciplines and a path to health promotion. A triple goal is pursued: provide pedagogic support, share a common view and langage, help with taking action.

Results:

6 theme-based document files were created. They were conceived as a collection, with a running gag in titles, colourful covers and numerous illustrations.

As for promotion and dissemination, they appeared on our website, on social networks, but also (Back to the Future?) printed as proper books and sent to our partners. Our team also got involved in methodological assistance, at university and in our resource centre.

Thanks to its formal innovation and its multidisciplinary audience, this production built a collective culture of health promotion. Overpassing sanitary service, it is now used by other professionals for different purposes, including project managers during training sessions.

Conclusions:

This action faced the recurring challenge of assessing a support function such as ours, but performed in becoming a showcase to promote our structure.

Information accessibility could be improved by better internet referencing, its attraction by infographics, its efficiency by evaluation. But above all, live interaction appears to be the key in a knowledge transfer strategy.

Key messages:

- Sanitary service is an opportunity to picture a common view on health promotion.
- As documentalists, let's build bridges to knowledge by turning into super mediators.

Physician-patient communication: A qualitative study of perceptions, barriers, and needs in 4 EU MS

Konstantina Zota

A Dalma[1], *K Zota*[1], *P Karnaki*[1], *A Veloudaki*[1], *A Linos*[1]
[1]Institute of Preventive Medicine, Environmental & Occupational Health, Marousi, Greece
Contact: d.zota@prolepsis.gr

Background:

Good physician-patient communication is an important aspect of patient-centered care and contributes to positive health outcomes. However there is a lack of standard EU communication training policies for physicians. This study explores the barriers to good communication for both physicians and patients across four EU countries as part of the EU-funded Project ''H-COM'', Health Communication Training for Health Professionals.

Methods:

Eight focus groups were conducted with a total of 31 patients and 38 physicians from Germany, Greece, Spain, and Cyprus. Three themes were covered; perceptions, barriers and needs for health communication.

Results:

Commonalities and differences between countries and target groups were identified, with participants discussing attitudinal, emotional, educational, and systemic barriers to good communication. Identified barriers among patients include a deeply embedded hierarchical notion and arrogance among physicians, inadequate or difficult to understand language, busy schedules. Among doctors barriers identified were mostly systemic having to do with busy schedules, large number of patients, and lack of time. Participants especially patients indicated a significant gap in health communication knowledge, skills, and training for physicians, with several regional differences being present especially between Mediterranean and central European countries.

Conclusions:

The results imply a strong need for communication training, tailored accordingly in specific countries. Further development of policies related to the inclusion of such training in medical studies across EU would be of great importance.

Key messages:

- There are differences concerning health communication needs and barriers between EU regions and the development of tailored training.
- Although identified as important there is a lack of health communication training in certain EU MS and an urgent need to incorporate training in basic medical and nursing education.

Predictors of job satisfaction in public hospitals in Belgrade, Serbia: a cross-sectional study

Katica Tripković

K Tripković[1], M Odalović[2], S Mladenović Janković[3], A Nešković[1], M Jakovljević[1]
[1]Analysis, Planning and Organization of Health Care, City Institute of Public Health, Belgrade, Serbia
[2]Social Pharmacy and Pharmaceutical Legislation, Faculty of Pharmacy, University of Belgrade, Belgrade, Serbia
[3]Health Promotion, City Institute of Public Health, Belgrade, Serbia
Contact: dr_cvrcak@yahoo.com

Background:

Growing evidence has suggested that job satisfaction in the health-care system can affect productivity, the quality of service, and patient safety. Knowledge regarding job satisfaction of health workers and its determinants is valuable to health-care managers for decision making in the field of personnel policy. This study was aimed to assess job satisfaction among health workers in public hospitals in Belgrade, Serbia and identify its associated factors.

Methods:

This was a cross-sectional study, carried out within 24 hours, in December 2018, as a part of a national survey, which is conducted annually in all health care institutions in Serbia. Data were collected by self-administered structured questionnaire, which was distributed to all health workers who were at work at the time of the survey (11,588 health workers in 26 public hospitals in Belgrade). The completed questionnaires were returned by 9,203 health workers, which constituted the response rate of 79.4%. Multivariable logistic regression was applied to identify factors significantly and independently associated with a higher level of job satisfaction.

Results:

Overall, 31.4% of the respondents were satisfied with their job. Age less than 35 years [AOR = 1.40; 95% CI (1.18-1.67)], no work stress [AOR = 2.66; 95% CI (1.94-3.65)], satisfaction with time for accomplishment of tasks [AOR = 1.92; 95% CI (1.64-2.26)], satisfaction with recognition and value of health workers' engagement [AOR = 1.79; 95% CI (1.51-2.13)], and satisfaction with leadership style and work organization [AOR = 1.90; 95% CI (1.60-2.26)] were identified as determinants with highest influence at job satisfaction.

Conclusions:

Less than third of health workers in Belgrade's hospitals were satisfied with their job, while satisfaction with various aspects of the job, age, and work stress, were identified as predictors. The results of this study could be useful in proposing strategies to improve job satisfaction of health workers.

Key messages:

- The job satisfaction of health workers in Belgrade's hospitals is low.
- Health-care managers should pay attention to create an environment that promotes job satisfaction and reduces work stress.

Implementation and development of guidelines in the emergency services in Kosovo – PARIHS framework

Ruhija Hodza-Beganovic

R Hodza-Beganovic[1,2], H Carlsson[1], H Lidberg[1], V Blaku[3], P Berggren[1,4]
[1]International Medical Program, Centre for Teaching and Research in Disaster Medicine, Linköping, Sweden
[2]School of Health Science, Örebro University, Örebro, Sweden
[3]Emergency Medical Services, Emergency Centre, Pristina, Kosovo
[4]Linköping University, Linköping, Sweden
Contact: Ruhija.Hodza-Beganovic@regionostergotland.se

Background:

The aim of this project is to create understanding on the determinant factors enhancing adherence to treatment guidelines for the emergency medical services in Kosovo (EMSK). Focus is on barriers, and enablers while introducing the guidelines. It is aiming to create clearance and understanding of how and why the implementation outcomes are achieved. The factors influencing implementation will be mapped in three main domains. The domains are part of the determinant framework Promoting Action on Research Implementation in Health Services (PARIHS). Each of the domains is further divided into sub-constructs.

Methods:

The process of implementing treatment guidelines into the emergency medical services in Kosovo was observed and documented by 4 researchers, using a participatory research design. The PARIHS framework that consists of three core components: evidence, context, and facilitation was applied to make clarity on what works better and why, in order to achieve the outcomes of the implemented guidelines.

Results:

The preliminary results have shown that the three constructs have an important role in the process of implementation. The domain evidence determined the way the evidence based practice is conceived in this particular setting. The domain context concerns the organization and teamwork shaped challenges and possibilities for adherence to the guidelines. The role of an external facilitator was of specific importance.

Conclusions:

The PARIHS framework serves in both practical and theoretical planning of an intervention. In the present project it provides clarity on planning of the process, while also offer understanding of the elements that contribute to the sustainability of the intervention. Finally the lessons from the approach can be replicated in similar context.

Key messages:

- Implementation projects can be more successful suing a framework to direct the effort.
- Such interventions should be premised with clarity on the evidence, the local context, and facilitation factors.

Preferences and expectations of graduates in nursing towards lifelong learning (Bulgaria, 2016-2019)

Gena Grancharova

G Grancharova[1], S Djulgerova[2], S Aleksandrova-Yankulovska[1], E Dimitrova[2]
[1]Faculty of Public Health, Medical University, Pleven, Bulgaria
[2]Faculty of Health Care, Medical University, Pleven, Bulgaria
Contact: gena_grancharova@hotmail.com

Background:

Nurses have a vital role to play in provision of high quality and safety health care in a global perspective. This is extremely valid for Bulgaria with the lowest nurses to doctors' ratio 1.1. The future nursing generations should be motivated for lifelong learning (LLL), irrespectively of scarce human and financial resources in health care. The aim of the study was to explore preferences, expectations and motivation of graduates in nursing towards LLL.

Methods:

A cross-sectional descriptive study was conducted among 174 bachelors in nursing (152 women and 22 men) before their graduation in 2016-2019 at the Faculty of Health Care in MU-Pleven. Anonymous self-administered questionnaire was used to collect information about graduates' work preferences, expectations and motivation for LLL (response rate 95%). Data processing was performed by SPSS v.24 using descriptive statistics and correlations. The accepted level of significance was $p < 0.05$.

Results:

Most of the graduates prefer high-technology clinics with only 13.2% for outpatient care and community centres; 50% plan to get higher educational degree; 81.5% will need a clinical mentor to start practicing. LLL is appraised by 82% as ultimate for nursing. It should be directed to developing skills and knowledge for effective team work (29.9%), capacity for self-directed practice and adaption to innovations (24.1%), skills to cope with critical situations (14.1%). The first motivating factors for LLL are professional development (44.3%) and better payment (37.4%). The most common demotivating factors: financial reasons (37.9), health problems (21.3), absence from home (13.8%), employer permission (13.8%). All the results have $p = .000$ for one sample x2 test.

Conclusions:

The graduates understand the crucial role and have realistic expectations of LLL for their professional development. Prevailing motives and demotivating factors correlate to the whole Bulgarian health system problems.

Key messages:

- The graduates in nursing at the Faculty of Health care in Pleven Medical University highly appreciate the role of LLL for their professional development and prestige.
- The schools in nursing should continue working to further motivation for LLL as indispensable requirements for contemporary effective and efficient nursing care delivery.

Clinical psychologists in primary mental health care in Norway - what to do?

Silje L. Kaspersen

SL Kaspersen[1,2], M Ådnanes[1], SO Ose[1]
[1]Health, SINTEF, Ranheim, Norway
[2]Department of Public Health and Nursing, NTNU, Trondheim, Norway
Contact: silje.l.kaspersen@sintef.no

Background:

The past 20 years Norwegian health authorities have put significant effort into increasing the number of clinical psychologists in primary health care. By 2020, all Norwegian municipalities are required by law to have clinical psychologists available. In 2018, only about half of the 422 municipalities had fulfilled this requirement, and the number of vacant positions is growing. The purpose of this study was to investigate the usefulness of clinical psychologists in a primary care setting as perceived from primary mental health care leaders/employees and those who educate clinical psychologists at the universities.

Methods:

We combined the use of open-ended questions in a survey (N = 456) among leaders and employees of primary mental health services in Norway, with data from semi-structured focus group and individual interviews (N = 15) with academic staff at the four universities in Norway that provides education for clinical psychologists.

Results:

The discussion on utilisation and usefulness of clinical psychologists in Norwegian primary care often condensates into weighing time spent on a never-ending demand for individual therapy against time spent on health promotion, prevention and system level work. Traditionally, Norwegian psychologists have received education mostly focusing on treatment methodology and individual therapy most suitable for the specialist services. The curricula are now changing towards more health promotion/prevention in primary care, but still lacks focus on system level approaches like collaboration with and guidance of other professions - which are the qualities asked for from those who hire clinical psychologists in primary mental health care.

Conclusions:

Interdisciplinary collaboration with a wide spectre of professionals and thereby 'working with and through others' in the health and welfare services, was suggested to be the most efficient way of utilising psychological clinical competence.

Key messages:

- The Norwegian clinical psychologists' education is becoming more primary care friendly.
- Psychologists in primary care must be part of interdisciplinary teams where they can work with and trough others.

FINDRISK and occupation: need of prevention of diabetes type 2 at the workplace

Karolina Lyubomirova

K Lyubomirova[1], M Tabanska[1], L Hristova[1], M Samuneva[1], M Yancheva[1], N Tzacheva[1]
[1]Occupational Health, Faculty of Public Health, Medical University Sofia, Sofia, Bulgaria
Contact: carol_lub@dir.bg

Background:

Diabetes mellitus is a risk factor for atherosclerosis, cardiovascular morbidity and increased mortality. Identifying people at a high risk of developing diabetes determine the prognosis and quality of life of the patients and prevent the development of macrovascular complications of diabetes. Within the framework of an international project, the ten-year risk of developing type 2 diabetes mellitus in two age groups workers (up to 25 and over 55) of four economic sectors (construction, clothing, hairdressing and cosmetics, and healthcare) has been estimated.

Methods:

The survey included 150 workers from four economic activities. The FINDRISK questionnaire was distributed among them. Plasma glucose and serum lipids (HDL, LDL, triglycerides) were analyzed. The statistical analysis of the results was done using SPSS 16.

Results:

The mean FINDRISK score for the age group up to 25 years is 3.6 ± 3.8, and for respondents above 55 years - 10.1 ± 5.0. The analysis highlights the higher risk of developing diabetes among healthcare workers, where the score of older workers is 11.63 ± 6.61, as well as in the textile and clothing industry (11.17 ± 4.3). These results call attention to a potential link between the occupation and the risk of developing type 2 diabetes in these sectors of the economy and the need for additional measures to search for causes and prevention.

Conclusions:

A significant proportion of the participants over 55 years old in the healthcare and textile and clothing sectors are at an increased risk of developing type 2 diabetes, which requires a change in lifestyle, as well as the identification of workplace hazards that lead to these results. The FINDRISK questionnaire can serve as an indirect assessment of the cardiovascular risk of older workers. Additional preventive measures are needed to limit the risk of developing type 2 diabetes mellitus as well as cardiovascular risk in the identified risky occupations.

Key messages:

- Occupation could contribute to the life style risk factors for developing diabetes type 2.
- Occupational risk reduction measures and health promotion are needed to protects workers.

A methodological support to set up multidisciplinary group practices in Southeastern France

Hélène Dumesnil

O Douchement[1], H Dumesnil[1], L Dagnet[2], B Saugeron[3], P Sonnier[3], P Verger[1,4,5], V Guagliardo[1,4,5]
[1]Southeastern Health Regional Observatory (Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur), Marseille, France

[2]Southeastern Regional Council (Région Sud Provence-Alpes-Côte d'Azur), Marseille, France
[3]Regional Committee for Health Education (Comité Régional d'Education à la Santé Provence-Alpes-Côte d'Azur), Marseille, France
[4]Aix Marseille University, IRD, AP-HM, SSA, Vitrome, Marseille, France
[5]IHU-Méditerranée Infection, Marseille, France
Contact: helene.dumesnil@inserm.fr

Issue/Problem:

Despite high medical densities in Southeastern France, access to prevention and care is difficult in some territories due to a lack of health professionals. The Regional Council supports multidisciplinary group practices (MGP) to improve primary care access and quality. When developing them, health professionals have to propose a health project addressing population health needs in the area.

Description of the problem:

Two complementary resource centres -the Southeastern Regional Health Observatory and the Regional Committee for Health Education- collaborate to provide support to health professionals in the creation of MGP. The process includes a territorial assessment based on quantitative indicators about various environmental and socio-economic determinants, morbidity, mortality, and health-seeking behaviours. Stakeholders then discuss the results of this assessment in order to confront it to their experiences, identify priorities and design the health project: it defines the forms according to which professionals will work together and set specific objectives and activities to cover main public health needs in the corresponding territory.

Results:

Since 2011, our methodological support has benefited 45 MGP projects: 19 were successful, 13 are still in progress and 13 projects were not completed. It helped decision-makers in the identification of priority territories in terms of prevention and care; it also presented outlooks of the current and coming health needs of various areas.

Lessons:

Levers to the MGP setting up have been identified: a project is more successful when it is initiated by health professionals supported by local authorities, and up for discussion. On the contrary, preconceived ideas about the MGP project complicate the assessment's appropriation.

Key messages:

- Taking into account the results of the assessment helps to propose MGP projects that better match population needs.
- It also improves collective knowledge of public health issues between health professionals and various local stakeholders.

Employment program graduates of internship of higher education institutions of Kazakhstan

Vitaliy Koikov

A Abdrakhmanova[2], Z Baigozhina[2], Zh Bekbergenova[1,2], A Umbetzhanova[1,2], G Kabdullina[2], V Koikov[2]
[1]NCJSC ''Astana Medical University'', Astana, Kazakhstan
[2]RSE on the REM, Astana, Kazakhstan
Contact: vitaliy.koikov@gmail.com

Background:

Employment of graduates of medical universities is one of the traditional problems of health care in the Republic of Kazakhstan (RK). The annual graduation of medical universities of RK exceeds 4500 young specialists. Despite this, as well as the positive dynamics of employment, the health care industry continues to experience a shortage of medical personnel.

Methods:

To take effective measures to improve the employment performance of graduates of medical education organizations, to cover the shortage of medical personnel, an analysis was made of the employment of graduates of internship programs at 8 medical universities for the period from 2014-15 to 2016-17 school years

Results:

For three years, medical schools of RK prepared 12019 people, of whom 8921 people studied under the state and 1343 under the rural grant. The total number of employed was slightly more than half of the graduates-6533, which amounted to 54.4%. At the same time, the number of those employed in urban hospitals is 1.5 times higher than the number of those employed in rural medical organizations. High percentages are persons who have continued their studies in residency/magistracy, and this figure tends to increase every year. The trend towards an increase is maintained by the free distribution index for pregnant women and people caring for children under the age of 3 years, for a total of three years it was 1,452 (12.1%) of a person. At the same time, those employed in rural health facilities are only 19.1% of those who studied under the grant and 31.5% of those who studied according to the rural quota.

Conclusions:

Thus, the percentage of employed graduates, as well as graduates who studied under the state and rural grant, barely exceeds 50%. Even the employment of persons trained in rural quotas in rural health care facilities is only 31.5%. Universities do not fully monitor the employment of graduates, especially those who studied under a state or a rural grant.

Key messages:

- To create and implement an electronic platform with a complete database of students and graduates.
- To monitor employment and track the graduate's work route; to organize employment services at universities.

DN Health workforce development and research

An Evaluation of Midwifery Education System in Armenia

Serine Sahakyan

S Sahakyan[1], L Aslanyan[1], S Hovhannisyan[1], V Petrosyan[1]
[1]Turpanjian School of Public Health, American University of Armenia, Yerevan, Armenia
Contact: s.sahakyan@aua.am

Background:

Competencies, knowledge and skills of health care professionals largely depend upon their education. Well-educated and competent midwives can improve women's and infants' health related outcomes. The current study evaluated the compliance of the current midwifery education system in Armenia with the global International Confederation of Midwives (ICM) standards.

Methods:

The research team used a qualitative cross-sectional study design with deductive content analysis. Through purposeful sampling we recruited five nursing colleges providing midwifery education in Armenia; two in the capital city and three in different regions. The study population included midwifery students, faculty and administrative representatives of the selected colleges (n = 56). During fall 2018, we conducted observations of midwifery education textbooks and equipment and in-depth interviews and focus group discussions with participants.

Results:

Despite widely used interactive teaching methodology and more than 60% of teaching time allocated for practical learning, students graduated from the program without obtaining essential competencies. Lack of teaching resources, especially in the regional colleges, and lack of quality clinical learning opportunities in hospitals were barriers for students to develop essential practical skills.

Conclusions:

The study recommends the governmental bodies to ensure provision of equity-based distribution of finances and tangible resources between the capital city and regional nursing colleges. The practical component of midwifery education programs need substantial enhancement.

Key messages:

- The lack of teaching resources and access to hospital sites were barriers to obtaining essential competencies for midwifery students.
- In order to develop a sufficient professional skillset, midwifery education programs should arrange comprehensive and structured practical experience for students.

Foreign workers' health in agriculture: assessing health workers' perception and training needs

Aurora Angelozzi

LM Salvatori[1], A Rinaldi[1], A Angelozzi[1], S Caminada[1], L Paglione[1], B Persechino[2], M Marceca[1]
[1]Department of Public Health and Infectious Diseases, Sapienza Università di Roma, Rome, Italy
[2]INAIL, National Institute for Insurance against Accidents at Work, Rome, Italy
Contact: aurora.angelozzi@uniroma1.it

Introduction:

Health and safety of foreign workers employed in agriculture and zootechny present several critical areas. The multidisciplinary project 'Livingstone', funded by INAIL and carried out by several Italian universities, aims to address some of these critical issues. One of the project research line focuses on health professionals and has the objective to investigate their perception of the risks to which foreign workers are exposed and their training needs.

Methods:

A 33 items questionnaire is being self-administered to social and health professionals of three Italian regions (Lazio, Lombardia and Campania) where agriculture is developed; the administration phase will last 13 months (2018, April - 2019, May). The questionnaire has been built starting from a literature review; a pilot study have been conducted in a pilot sample in Rome in March 2018. The questionnaire is composed by five sections: general, social and professional information; characteristics of the respondents' foreign patients/users; knowledge about health problems of foreign patients and about possible obstacles in use of health services, with a specific focus on foreign patients working in agriculture and zootechny sector; perception about health and safety risks of these workers; training background and needs, included desired training contents and modalities.

Results:

The research is ongoing. 238 answered questionnaires have been collected yet. 65 of the respondents are General Practitioners; the rest are other health and social professionals. The complete results will be shown during the congress.

Conclusions:

This study will contribute to widen the knowledge about health professionals' perceptions about problems and needs of foreign workers employed in agriculture and zootechny sector. Specific training addressed to social and health professionals will be developed from the observation of their current knowledge and from their reported needs.

Key messages:

- This study will contribute to widen knowledge about health professionals' perceptions about problems and needs of foreign workers employed in agriculture and zootechny sector.
- Specific training addressed to social and health professionals will be developed from the observation of their current knowledge and from their reported needs.

What do health workers think about a population exposed to health inequalities? The Bastogi case

Susanna Caminada

LM Salvatori[1], M Tofani[1], A Angelozzi[1], S Caminada[1], L Paglione[1], S Iorio[2], G Ricotta[3], AM Brandimarte[4], D Biliotti[4], M Marceca[1]
[1]Department of Public Health and Infectious Diseases, Sapienza Università di Roma, Rome, Italy
[2]Department of Molecular Medicine Unit of History of Medicine, Sapienza Università di Roma, Rome, Italy
[3]Department of Social Sciences and Economics, Sapienza Università di Roma, Rome, Italy
[4]Local Health Unit, Roma1, Rome, Italy
Contact: susanna.caminada@uniroma1.it

Introduction:

Previous qualitative researches highlighted that people living in Bastogi - a peripheric area of Rome marked by social deprivation - have difficulties in accessing and relating health services. We explored the healthcare workers' perception of the relationship with such population.

Methods:

A 42 items questionnaire was addressed to the reference Local Health Unit employees, evaluating: context knowledge; perception of the relationship between users and health services and between users and operators; training needs. The association between answers and social characteristics of the respondents has been evaluated through Chi Square Test for categorical variables and T Student Test for continuous variables.

Results:

Questionnaire respondents were 73 (50% of the total employees). 77% reported knowing Bastogi. Adverse social determinants mostly identified (>65%) were economic problems, housing conditions and unemployment, while less people pointed out the poor social support network (38%).

50% assumed that Bastogi inhabitants face health inequalities. 26% claimed to have difficulties in the

relationship with users; 81% considered useful a training activity about the relationship with socioeconomic deprived users. 25% believed the responsibility for the main social problems in Bastogi lies in the inhabitants themselves. Such answer was statistically more frequent among: administrative professionals, professionals with longer length of service, those who deny the existence of health inequalities and those who don't feel the need of training. Further results will be presented during the congress.

Conclusions:

Preliminary results of the survey confirm that the relationship between users from a socially deprived area and the competent services is problematic, and underline the need for training of healthcare professionals on the subject. This need is also perceived by the majority of the respondent personnel.

Key messages:

- We explored the healthcare workers' perception of the relationship they have with a population exposed to health inequalities.
- Interventions and trainings will be implemented to contain this problem.

Midwifery in Germany – The necessity of developing a workforce and service planning approach

Manuela Raddatz

M Raddatz[1,2], C Hellmers[1,2], F zu Sayn-Wittgenstein[1,2], S Stelzig[1]
[1]Verbund Hebammenforschung, Hochschule Osnabrueck, Osnabrueck, Germany
[2]Department für Pflegewissenschaften, Universitaet Witten, Herdecke, Witten, Afghanistan
Contact: m.raddatz@hs-osnabrueck.de

Background:

Midwifery care in Germany is a legal right for every woman (SGB V). Midwives work employed or freelance in hospitals or in community services, providing maternal care from pregnancy until the end of breastfeeding (Sayn-Wittgenstein 2007). Increasingly, a shortage of midwifery care has been observed, forcing hospitals to understaff or to close their birth units, leaving women and their families without care (Sander et al. 2018). At the same time, birth rates are rising, thus leading to an increasing demand of midwifery care (Destatis 2019). As off today there is no central register for midwives across Germany's 16 states. Therefor the exact number of registered midwives as well as the scope of services provided by midwives are not known (Niedersächsisches Landesgesundheitsamt 2019). Given the present situation, it seems to be imperative to establish effective midwifery workforce planning.

The aim of this poster is to identify already existing health workforce planning approaches and to determine the extent to which those can be transferred to the German system of midwifery care.

Methods:

Health workforce planning approaches, already being used on a national and international level, have been analysed, focusing their applicability to midwifery services in Germany.

Results:

Particular elements of the workforce planning approaches already being used in Germany for registered physicians seem to be adoptable. However, they need to be adjusted and enhanced to ensure the characteristics of midwifery in the German public health services. Internationally used approaches are not readily transferable due to systemic differences in health care systems.

Conclusions:

The development of new specific workforce and service planning approaches for midwifery care in Germany is crucial to meet present and future needs of women and their families during the childbirth period.

Key messages:

- It seems sensible to consider the peculiarities of a healthcare system in midwifery workforce planning.
- Establishing workforce research still represents an important task for midwifery in Germany.

The AAPRISS Platform: Learning and Taking Action to Reduce Social Inequalities in Health to help PHIR

Michelle Kelly Irving

T Lang[1], C Marquis[2], N Haschar-Noé[3], M Kelly-Irving[1], M Huot-Royer[2], P Grosclaude[1], C Delpierre[1]

[1]UMR 1027, INSERM, Université de Toulouse Paul Sabatier, Federative Institute of Interdisciplinary Research and Studies Health Society (IFERISS FED4142), Toulouse, France

[2]Federative Institute of Interdisciplinary Research and Studies Health Society (IFERISS FED4142), Toulouse, France

[3]CRESCO, Université Toulouse 3 Paul Sabatier, Federative Institute of Interdisciplinary Research and Studies Health Society (IFERISS FED4142), Toulouse, France

Contact: michelle.kelly@inserm.fr

Today, the reduction of social inequalities in health is on the political agenda in public health. The complex reality of the determinants of these health inequalities remains difficult to understand and translate into practical actions. One of the reasons is that the circulation of expertise amongst researchers, actors in the field, and public decision is not systematic and still too rare.

In 2013, the Federative Institute of Interdisciplinary Research and Studies Health Society (IFERISS) of Toulouse has an interdisciplinary platform (health, the humanities, and the social sciences) that directly offers expertise to public health actors, institutions, and local communities in order to respond to public health issues.

At the request of the actors, AAPRISS can intervene at all stages of a study or an intervention, from conceptual and methodological construction to implementation support, and data analysis and use. In particular, the team has expertise in public policy evaluation, support for transferability according to the key functions/implementation/context (FIC) model, and awareness-raising at the intersection of urban planning and health. The platform is in a multi-year partnership with local authorities, the regional health agency of Occitanie, the primary health insurance funds of Occitanie, and various partners in civil society. Six years after the establishment of the AAPRISS platform, there is a strong demand for support and research from the actors and institutions. However, funding for activities remains uncertain despite the support of the National Cancer League and an increasingly strong network of partners. Mixed structures housing spaces for both research and action, which create a dynamic of Population Health Intervention Research, are showing themselves to be effective and seem to meet a need, but their financial stability is insufficient to sustain their activities and promote sustainable reduction of social inequalities in health.

Key messages:

- Mixed structures housing spaces for both research and action, which create a dynamic of Population Health Intervention Research, are showing themselves to be effective and seem to meet a need.
- But the financial stability of this mixed structures is insufficient to sustain their activities and promote sustainable reduction of social inequalities in health.

Pre-participation screening of the athletes in Turkey: approach of primary care physicians

Kubilay Kaymaz

M Dursun[1], E Bilir[1], K Kaymaz[1], S Sakarya[2]

[1]School of Medicine, Koç University, Istanbul, Turkey

[2]Public Health, Koç University, Istanbul, Turkey

Contact: kkaymaz@ku.edu.tr

Background:

The pre-participation screening is crucial as the risk of sudden death for competitive athletes is higher than that of non-athletes. In Turkey, screening could be performed at the primary health care setting both by family medicine specialists (FMSs) and by general practitioners (GPs). Although there is a guideline, there is no legal regulation for the process. The aim of this study is to evaluate the approach of primary care physicians in pre-participation screening.

Methods:

An online questionnaire based on the Turkish Medical Association (TMA) guideline, and the 14-item Screening Guideline of the American Heart Association (AHA) was delivered to primary care physicians. Knowledge, experience and approach of the physicians were assessed. Self-confidence, application of AHA criteria, accurate referral ratios and further test requests were taken as outcome measures. Descriptive and inferential analyzes were performed and $p < 0.05$ was considered significant.

Results:

Of 214 participants, 39.3% were women, the average age was 44.9 years, the average work experience was 7.9 years. 89.7% of the participants were aware of their authorization, 90.2% had previously given this report, but only 6.5% feels confident. Only 13.1% knows the presence of TMA guideline, and only 23.8% states being educated on the subject at any part of their career. More than 60% of the participants consider further testing necessary in addition to medical history and physical examination. Blood and urine test requests were significantly more for GPs compared to FMSs ($p = 0.026$, $p = 0.011$). Accurate referral decision ratio was only 59.3% with no difference between FMSs and GPs ($p = 0.216$). Work experience had no effect on any of the outcomes.

Conclusions:

As the legal regulations and awareness of the guideline are insufficient, pre-participation screening is not standardized, and this increases tendency for further testing or referral.

Key messages:

- The pre-participation screening of athletes in Turkey is not standardized among primary care physicians.
- Further testing request ratio is high and accurate referral ratio is low.

Key Aspects of Modernizing Public Health Doctoral Program at The University of Georgia

Tamar Lobjanidze

T Lobjanidze[1], G Kamkamidze[1], K Antia[1]
[1]School of Health Sciences, University of Georgia, Tbilisi, Georgia
Contact: t.lobjanidze@ug.edu.ge

Structured Doctoral Program of Public Health has been modernized from ‘‘consultation’’ to combined ‘‘Multi-methods’’ teaching module at the University of Full PhD program consists of 180 ECTS, 3 years for the full-time, and maximum of 7 years for the part-time. The programme consists of 60 teaching and 120 ECTS Research component. Doctoral student, together with a supervisor, starts working on his/her dissertation from the 1st academic year/semester of enrollment Transition from ‘‘consultation’’ model to the ‘‘combined multi-methods’’ model advances the learning outcomes, straight research skills, internationalization, modern professional communication.

PH PhD Program aims to prepare a public health researcher who will be able to identify and solve public health issue/problem, produce the best evidence possible and make an evidence-based decisions, create a novelty, and expand the knowledge borders of public health. Self-administrated semi-structured questionnaire were used: How much ‘‘consultation’’ model is effective? What kind of skills are is necessary for scientific carrier?Focus-group discussion was conducted with PhD program graduates. Questions discussed: How you applied acquired skills and knowledge to your work/practice?In focus group discussion employers were asked to discuss what skills and knowledge they are requiring from the employees, if they are considering involvement of local and International experts in teaching process.

98 % of questionnaire students underline the Combined multy- methods with intensive theoretical and practical teaching with international activities. The deep knowledge of scientific methods and project writing skills are very important. Results of researches must be presented at the international scientific conferences and published.

Research methods course was improved (amounts of credits was increased 2 times).The frame of teaching is Combined multy-methods with internationalization involvement and with intensive timeline.

Key messages:

- The learning process consist of Combined multy-method, with deep research methods and internationalization activities. The elements of Research component starts from the 1st semester.
- Result Internationalization.

Evaluation of medical students to interest in the health research in Kazakhstan at 2018

Vitaliy Koikov

A Akanov[1], V Koikov[1], A Abduazhitova[1], A Aubakirova[1], D Otargalieva[1]
[1]Center for Education & Science Development, Republican Center For Health Development, Nur-Sultan, Kazakhstan
Contact: vitaliy.koikov@gmail.com

Background:

Since medical education is significantly different from other conditions of higher education, it is necessary to analyze the influence of the health research component on the quality of training a future health specialist.

Methods:

A quantitative analysis based on the survey. 2 types of original questionnaires were based on the AGREE method: a) to analyze the involvement of medical students, and b) to analyze the teachers of medical universities to integrate health research into the educational process. The survey involved 1,439 medical students.

Results:

85±1.02% of medical students agree that the triangle of science, education and practice is the main principle of doctors. 63±2.76% of students indicate a discussion with the teacher about the latest advances in medical science. 77±3.24% of surveyed students believe that health research is conducted at a good level. 78±5.8% of students confirm a good health research infrastructure at the University. The continuity of the scientific school and the discussion of the health research results was confirmed by 74±1.24% of students.

Evaluation of the participation of teachers in the study showed that 32±3.41% of respondents do health research at the time of the survey. 63±7.1% of teachers agree that the ‘‘science-education-practice’’ triangle is the main principle of doctors. 70±5.17% of teachers indicated the use of Case-based learning, Project-based learning and Research-based learning in their teaching practice.

Conclusions:

The analysis showed a lack of involvement of medical students in health research and a lack of commitment of educational organizations to the principle of the triunity of science, education and practice.

Key messages:

- Medical students who are engaged in research have professional competencies related to the practical use of their knowledge and skills than their peers who are not involved in research.
- Involving medical students in research provides benefits for Universities, medical students and stakeholders.

User typology for workplace health offers

Elisabeth Noehammer

E Noehammer[1], H Stummer[1]
[1]UMIT - Department of Public Health, Health Services Research and HTA, Hall in Tirol, Austria
Contact: elisabeth.noehammer@umit.at

Background:

Workplace Health Promotion/Management (WHP/M) is not mandatory in Europe. However, it is often considered to be a standard for attractive workplaces, but this does not necessarily result in high use. This opens the question if WHP/M is perceived only as quality criterion, or if the offer per se needs to be adapted. In this study, we therefore analyze the user typology for the WHP/M offers in four organizations

Methods:

A self-administered quantitative Likert-scaled questionnaire was filled in by the employees (N = 237) regarding use of offers, determinants of use, perceived attendance barriers and effects, interests, and demographic questions. We determined user profiles using cluster analysis and here focus on perceived barriers of use, reporting first results.

Results:

We found three clusters that mainly differ regarding intensity and type of perceived barriers. Cluster 1 experiences barriers to be very high, Cluster 2 reports very low barriers, Cluster 3 feels almost no information related, but intensive offer related barriers. Regarding demographics, there are more men in Cluster 2, women perceived barriers more intensively. Employees belonging to Cluster 1 are younger than those in Cluster 2; Cluster 3 is close to Cluster 1 regarding age. Additionally, Cluster 1 is made up of employees who are better educated, have joined the current employer more recently, have a better position and work less hours than those in the other clusters.

Conclusions:

Employees visibly diverge regarding perceived attendance barriers. Current WHP/M offers seem to be better adapted to those with lower position, longer working hours and more experience with the employer - or the employer with them.

The potentials of WHP for integrating all employees have not yet been realized. This is critical should the possibility to us WHP/M offers i.e. play a role for newly hired part-timers or high potentials.

Key messages:

- Companies offering WHP/M need to prioritize reducing offer related barriers and respond to divergent user profiles.
- Workplace health programs do not yet reach their potentials due to attendance barriers.

Nurses' experiences with the Implementation of a Manchester Triage System in an Emergency Department

Elisabeth Noehammer

M Raich[1], N Lorenzoni[1], S Angerer[1], E Nöhammer[1], H Stummer[1]
[1]Institute for Management and Economics in Healthcare, UMIT - University for Health Sciences, Medical Informatics and Technology, Hall / Tyrol, Austria
Contact: Elisabeth.noehammer@umit.at

Background:

Emergency Departments (ED) are very often confronted with a high number of non-acute patients. This circumstance has negative effects on the quality of care because of limited human resources and infrastructure in dealing with overcrowding. In Spring 2017 an Austrian hospital has implemented the Manchester Triage System to improve the management of patient flows. From the date of implementation the nurses were responsible for the preliminary assessment of the patients. The aim of this study was to investigate the nurses' experiences and attitudes concerning the implemented Manchester Triage System as well as its impact on their work and quality of patient care.

Methods:

A qualitative approach was chosen. In order to get a deep insight interviews with ten nurses were conducted by using an interview guide with open questions. The answers of the interviewed people were recorded, transcribed and analyzed by the qualitative method GABEK (GAnzheitliche BEwältigung von Komplexität).

Results:

The triage process has changed the working hours, processes, collaboration, task responsibilities and stress levels. The triage process itself is defined by the nurses as diversified activity with a high degree of responsibility. Experienced, well-trained nurses guarantee an appropriate preliminary assessment of the patient. Teamwork and backing by nurses and physicians are of importance in the case of unclear patient assessments. Finally, more time is available for acute patients in order to provide them an appropriate care.

Conclusions:

The Manchester Triage System has changed the nurses' working conditions and influences positively the management of patient flow and quality of care.

Key messages:

- The activities of the nurses have changed into diversified tasks with a high degree of responsibility.
- The implementation of the Manchester Triage System has a positive impact on the patient flow and quality of care.

ASPHER V4 Working Group supports the road map for professionalising the public health workforce

Alena Petrakova

A Petrakova[1], R Otok[2], V Prikazsky[3], M Dlouhy[4,9], Z Prazanova[1], L Stepanek[1,5], A Ghazal Asswad[6,7], N Fundano[6], H Khan[6], S Holm[6,8]
[1]Department of Public Health, Faculty of Medicine & Dentistry, Palacky University Olomouc, Olomouc, Czech Republic
[2]ASPHER, Brussels, Belgium
[3]National Institute of Public Health, Praha, Czech Republic
[4]Czech Society of Public Health and Management of Health Services, Praha, Czech Republic
[5]Department of Occupational Medicine, Faculty of Medicine & Dentistry, Palacky University Olomouc & University Hospital Olomouc, Olomouc, Czech Republic
[6]Faculty of Medicine & Dentistry, Palacky University Olomouc, Olomouc, Czech Republic
[7]Emergency Department, West Middlesex University Hospital, London, UK
[8]Department of General Surgery, Örebro University Hospital, Örebro, Sweden
[9]Department of Econometrics, University of Economics, Praha, Czech Republic
Contact: alenapetrakova@gmail.com

Background:

The ASPHER V4 Working Group (WG) was established in 2016 and officially launched during the 9th European Public Health Conference in Vienna. One of the key objectives of the WG is to strengthen public health capacity development in V4 countries. The WG supports the implementation of the recently reviewed European Action Plan for Strengthening Public Health Capacities (EAP). The EAP's review highlighted the need to focus further action on four enabling Essential Public Health Functions (EPHOs) including human resources for public health. This is why the WG is heavily involved in the recent development of a new Road map for professionalising the public health workforce, one of the products of the recently established Coalition of Partners (CoP) that was convened by the WHO Regional Office for Europe in close cooperation with ASPHER and Maastricht University.

Objectives:

- Supporting the WHO CoP with a focus on development and further implementation of a new Road map for professionalising public health workforce in V4 countries.
- Using a new rapid assessment tool to evaluate the state of the public health profession in the Czech Republic.
- Sharing the report on the current state of public health professions in the Czech Republic with the WG and using it as a comparison of the current state in all V4 countries.

Results:

1. Key strengths and weaknesses of the first rapid assessment of the current state of the public health profession in the Czech Republic are presented.
2. Key actions are proposed for the WG: a) Preparation of a grant proposal to the International V4 Fund and b) Continuing active involvement in CoP activities.

Conclusions:

The rapid assessment tool for evaluating the state of the public health profession was successfully implemented in the Czech Republic with the close cooperation of academia, researchers, policy makers and practitioners. The summary confirms that further work on the professionalization of the public health workforce is needed.

Key messages:

- ASPHER V4 WG is strongly involved in the development of a new road map for professionalising the public health workforce, coordinated by the WHO CoP, ASPHER and Maastricht University.
- Summary of the first rapid assessment of the current state of the public health profession in the Czech Republic confirms the importance of further action in this area of work.

Socioeconomic and health differences in physical activity: a cross sectional study in Lithuania

Audrius Dedele

A Dedele[1], A Miskinyte[1]
[1]Department of Environmental Sciences, Vytautas Magnus University, Kaunas, Lithuania
Contact: audrius.dedele@vdu.lt

Background:

Physical activity (PA) influences people's individual health and quality of life and contributes to prevent non-communicable diseases. Research shows that only one third of the EU inhabitants satisfy the World Health Organisation's recommendations for PA levels. Global decline in PA levels is associated with economic development, an increase in urbanization, communication technologies and the use of passive modes of transport. The aim of the study was to assess the levels of PA depending on socioeconomic factors and health among adults.

Methods:

A cross sectional study of a random sample of Kaunas residents was conducted to investigate the habits of PA. A representative sample of 1111 individuals who completed the questionnaire were included in the study. Validated questionnaires were used to collect data. Multivariate logistic regressions were used to assess the relationship between the levels of PA and socioeconomic factors and health, adjusting for confounders.

Results:

Our findings showed that non-workers were three times (OR 3.16; 95% CI 1.23-8.13) more likely to reach the levels of recommended PA compared to workers. The results revealed that car disposal and the increase in body mass index (BMI) were the two most important factors that reduced odds of reaching recommended levels of PA by 64 % (OR 0.36; 95% CI 0.14-0.93) and 13 % (OR 0.87; 95% CI 0.80-0.96).

Conclusions:

The differences in PA levels by individual socioeconomic factors and health were investigated in this study. The European Commission actively promotes Sustainable Urban Mobility Planning by developing guidelines for the local authorities to promote active mobility and increase PA.

Key messages:

- The study highlights the importance of considering different individual characteristics when assessing PA and evaluating related health effects.
- It is important to improve the accessibility of urban areas and create cleaner and more sustainable transport modes to increase PA.

DO Healthy living and health promotion

Health promotion, community-campus-local authorities partnership and new health professional profile

Sandrine Motamed

S Motamed[1]
[1]Institute of Global Health, Genève, Switzerland
Contact: motamed@bluewin.ch

Issue:

Meinier is a county near the city of Geneva, Switzerland. Following an initial study aiming to identify its residents' health needs, the local authority formally engaged our Institute to try to resolve the problems disclosed, which were of socio-economic and psycho-social nature. Our objective was to demonstrate that a collaborative approach to implementing effective intersectorial health promotion works at county level and that there is a need for a new role for public health, working at county level.

Description of the problem:

Numerous meetings of the inhabitants gradually developed into a community-wide dialogue, leading them to clearly define their requirements. Old people felt isolated and wished to remain in the village, rather than enter a nursing home elsewhere. Young families could not get established because of a lack of available housing and nonexistent day care facilities for children. Social links between people had diminished. Further difficulties arose from poor mobility.

Effets:

Given these findings the inhabitants drew together to develop a more equitable society, in a partnership between the authorities and our Institute. A participative intersectorial approach allowed a global program to be put together, which particularly united housing, urbanism, ecology and mobility. The project, driven completely by community participation, is now in its fourteenth year, its 40 million dollar budget adopted by community vote.

Results:

One prominent aspect is the new village center, with its sheltered housing for the elderly, affordable accommodation for young families, child day care, a games library, shops and a restaurant as well as an intergenerational park and living space.

Lessons:

The learning and experience gained in terms of community participation and of behavioral and social health determinants has been very important for all concerned.

Key messages:

- A collaborative approach to implementing effective intersectorial health promotion works at county level.
- There is a need for a new health professional profile (the county practitionner).

The Relationship between strength and academic performance: A new reason to promote physical activity

Jhonatan Peña

J Peña[1], *C Yanez*[1], *C Gomez*[1], *W Martin*[1], *C Castillo*[1], *J Granados*[1], *M Riveros*[1]
[1]IMED, Fundación Universitaria del Área Andina, Bogota, Colombia
Contact: jpena69@areandina.edu.co

Background:

Experimental studies have determined that higher strength values are associated with more efficient cognitive function and better academic performance. In spite of this, the universities in Colombia are decreasing the time available for physical activity in favour of increasing the time devoted to theoretical subjects. This is one of the reasons why in Colombia, only 18% of young people complied with the world recommendations of physical activity. To examine this problem, the objective of this research was to establish the relationship between strength and academic performance in university students.

Methods:

A cross-sectional study was developed in 135 (21.8 ± 4.5 yr; 78.69 ± 9.1kg) students of the fifth semester of the Areandina University in Bogota, Colombia. Each participant developed incremental protocols to determine the maximum weight that he or she could move in six different exercises: squat in smith machine, leg press, leg extension, bench press, pull down and military press. The average of the results of these tests was taken as the value of maximum strength. To determine academic performance, the average of the scores accumulated in the five semesters of their university studies was evaluated. Pearson correlation coefficient was used to find the linear relationship between strength and academic performance.

Results:

Overall, 70.3 % of the participants were men and 29.7% were women. The results of the maximum strength tests were significantly higher in the male group than in the female group ($P < 0.05$). Academic performance was similar in both genders ($P > 0.05$). A positive correlation was established between maximum strength and academic performance. ($r = 0.64$ $P < 0.05$).

Conclusions:

The conclusion of this research was that there is a significant relationship between strength and academic performance. These results are fundamental to justify the inclusion of spaces for the promotion of physical activity in public and private universities.

Key messages:

- Universities are institutions that only focus on academic training and generate contexts in which sedentary behaviours are promoted.

- Sedentary lifestyles are a public health problem in Colombia.

Health promotion among the unemployed: an international systematic review

Alfons Hollederer

A Hollederer[1]
[1]The Faculty of Human Sciences (FB 01), University Kassel, Kassel, Germany
Contact: alfons.hollederer@uni-kassel.de

Issue:

The interactions between unemployment and health create a need for specific interventions for health promotion and prevention.

Description:

This overview provides information on how health promotion for the unemployed has been approached with an analysis of controlled intervention studies between 1996-2016. The literature search consulted 11 international databases in medicine, social sciences and psychology. A total of 30 health interventions for the unemployed were identified, with 43 articles that included the effects of intervention.

Results:

A controlled-study design was used in 14 studies. The health promotion measures were generally based on individual counselling, case management, training or group services. The overview demonstrates the breadth of variation in target groups and types of measures. Their result indicators for health and labor market integration vary substantially. Effects are rather moderate or low in magnitude and the effect mechanisms often remain unclear. Effects weaken over time. While success is more common in the areas of health, physical activity, nutrition and stress relief, there was no impact on smoking behavior.

Lessons:

A significant evolution can be observed in the quality and quantity of health promotion over time. There is a need for further research on the effectiveness and sustainability of interventions.

Key messages:

- There is evidence of improved health and labor market integration for established approaches like the JOBS Program and JobFit.
- Intervention strategies should be developed that take account of the diversity of the unemployed and their different needs.

Health literacy of commercial industry managers: an exploratory qualitative study in Germany

Holger Pfaff

H Pfaff[1], *S Fiedler*[1]
[1]IMVR, University of Cologne, Cologne, Germany
Contact: holger.pfaff@uk-koeln.de

Background:

Managers have been neglected in health literacy research. There still is little known about the health literacy status and needs of commercial industry managers. This study reduces the existing knowledge gap by presenting findings of an exploratory qualitative study.

Methods:

We conducted 23 separate semi-structured interviews of managers from all management levels (low, middle and top) and experts in the field of health management and/or personnel management. The qualitative interviews were analysed according to Mayring's content analytic approach using MAXQDA.

Results:

The findings indicate that managers do have considerable information levels about existing health topics and relevant problems but have difficulties of discernment as to which sources of information can be activated or accessed in a timely fashion due to work and information overload. Even those who devise strategies often fail in implementing health-literate behavior. Experts and managers had fairly consistent views on the importance of health literacy among managers. Most agreed that mental health was neglected and that company conditions were important in influencing the ability to act in a way that promoted health literacy. The findings also show that strengthening of managerial self-perception, self-regulation and self-control, raising awareness and ability to take personal responsibility for one's own health, developing skills in handling large amounts of information and fostering open and trusting communication are all essential.

Conclusions:

The findings provide specific points which are important for promoting health literacy among managers. The study underscores the need to incorporate and integrate different perspectives in the implementation of health literacy interventions. To develop health-promoting companies, further research has to provide guides to action for managers and investigate ways in which health literacy can be promoted among managers on all hierarchical levels.

Key messages:

- Industry managers in this study agreed that their mental health has been neglected and company conditions were important in influencing the ability to act in a way that promoted health literacy.
- This study reduces the knowledge gap about the health literacy of managers. Further research should focus on promoting mental health and providing guides to action for managers and companies.

Who has access and who participates in parkrun? - implications for selecting future event locations

Paul Schneider

PP Schneider[1], *R Smith*[1], *A Bullas*[2], *S Haake*[2], *A Brennan*[1], *E Goyder*[1]
[1]School of Health and Related Research, Sheffield University, Sheffield, UK
[2]Advanced Wellbeing Research Centre, Sheffield Hallam University, Sheffield, UK
Contact: p.schneider@sheffield.ac.uk

Background:

parkrun is an international organisation which hosts free, weekly volunteer-led, running events. More than 300,000 people participate across 21 countries each week. The present study investigates how access to, and participation in, parkrun events varies across England. We go on to make policy recommendations for new parkrun event locations, in order to maximise geographical access and participation whilst taking account of the impact on inequalities.

Methods:

We combined location data of census areas, parkrun events and public parks in England. For the census areas, access was defined as the distance of the area's centroid to the nearest parkrun event, and parkrun UK provided information on 2018 participation rates per area. Linear regression was used to investigate the effect of deprivation on access, and the effect of deprivation and access on utilisation. We propose a flexible algorithm for identifying optimal new parkrun event locations and provide two sample sets of recommendations.

Results:

The median distance to the nearest parkrun event was 3.4 km, but the distribution was heavily skewed: for approximately 10% of the population, the nearest event was more than 10 km away.

Despite statistical significance, the relationship between deprivation and access was very weak. However, access and deprivation had a considerable effect on participation: less deprived areas, and areas with good access had higher participation rates. The best locations for new events are contingent on what parkrun aims to maximise. We demonstrate that optimal locations for maximising equitable geographic access differ from locations for maximising participation.

Conclusions:

Access to parkrun is generally good and is similar across socioeconomic groups, but participation is markedly higher in less deprived areas. Our algorithm can be used by parkrun to further improve access for deprived communities. However, better access alone is unlikely to reduce inequities in participation.

Key messages:

- In England, access to parkrun is generally good, and our algorithm can be used to further optimise it.
- However, better access alone is unlikely significantly increase participation from deprived areas.

Exploration of perceptions of health of low SES citizens in the Netherlands

Marja de Jong

MAJG de Jong[1,2], *AE Wagemakers*[2]
[1]Public Health Service IJsselland, Zwolle, Netherlands
[2]Health and Society, Wageningen University and Research, Wageningen, Netherlands
Contact: m.de.jong@ggdijsselland.nl

Background:

Health promotion programs (HPPs) have not yet succeeded in substantially reducing the health gap between higher and lower socioeconomic groups. It is thus a challenge to develop more effective strategies, based on an ecological perspective. To develop such strategies and activate citizens, this study explores citizens' perceptions of health and what they need to improve it.

Methods:

Setting Community HPP Voorstad on the Move (VoM) (July 2016-Jan 2020) in a district (+-11,000 inhabitants) in Deventer. Inhabitants' socioeconomic status (SES), perceived health status and lifestyle are low relative to other city districts. Study design: A qualitative study of 11 community groups (n = 89) participating in two focus groups. Concept mapping was used to cluster and prioritize health perceptions. Social Practice Theory (SPT) guided the analysis of needs to change health-related behavior.

Results:

''We don't assume that everyone has the same idea about health, do we?'' (citizen)

Participants differed in age (16-82), cultural background (17% non-Dutch origin) and type of group activity. High-ranking dimensions of health are social relations, physical activity, a positive life attitude, healthy eating and empowerment. To improve health, social support from family and friends and self-confidence were the main needs. Physical impediments, (chronic) illness and financial aspects were also mentioned as barriers. The focus groups contributed to new activities as part of the VoM program facilitated by a health broker: e.g. a swimming group, biking buddies, social meetings.

Conclusions:

Citizens perceive health as multidimensional, encompassing the physical and social environment, lifestyle behaviors, positive attitudes and being in control. Using SPT to unravel these needs in terms of meanings and competences helped to facilitate citizens' active involvement in health-promoting activities.

Key messages:

- Low SES citizens perceive social relations, physical activity and a positive life attitude as important dimensions of health.
- Insight into citizens' meanings and competences about health behaviors facilitates the development of health-promoting activities.

The structure and forms of physical activity in the City of Zagreb 2O14/2015

Ana Puljak

A Puljak[1], *M Zivec*[1], *M Polic-Vizintin*[1], *H Radasevic*[1], *Z Sostar*[1]
[1]Department of Public Health, Andrija Stampar Teaching Institute of Public Health, Zagreb, Croatia
Contact: ana.puljak@stampar.hr

Background:

Physical inactivity is one of the biggest public health problems of the 21st century. It is carried through walking, cycling, job, sports, recreation. The aim of this paper is to evaluate the physical activity of the citizens of Zagreb according to sex, age and the type of physcal activity. Health-Enhancing Physical Activity recommendations are at least 150 of moderate or 75 vigorous minutes activity per week.

Methods:

The research has been conducted by analyzing the data gained from the European Health Interview Survey (EHIS 2) from the World Health Organization that was carried out in Croatia during 2014. and 2015. There were collected the data on the frequency, duration and type of physical activity in the City of Zagreb. The target population was aged over 15 and included 446 inhabitants (188 men and 258 women) of the City of Zagreb.

Results:

24,5% of the total number of physically active persons exercise between 150 and 300 minutes per week. 45, 0 % respondents walk 10 to 29 minutes daily, 27, 1% walk 30-59 minutes daily, 14, 9% walk 1 or more hours a day. 1,2% respodents spend less then hour, 13, 6% spend 1 hour and 59 minutes, 18, 3% spend 2.00-2.59 hours and 8, 3% spend 3-3.59 hours on sport and recreation per week. 13, 8% of citizens spend 10-29 minutes a day cycling, 30.1% cycling 30-59 minutes a day, 12, 2% cycling 1 hour to 1 hour and 59 minutes and 2.4% spending more than 2 hours a day on a bicycle. When doing a professional job or work at home 43, 7% of respondents mostly sit or stand, 32,3% use moderate physical effort and 1, 5% of people perform hard work. 14.4% of respondents are engaged in sports, 11.9% cycling and 71, 9 % respondents walk 3-7 days a week.

Conclusions:

Zagreb's citizens are not sufficiently engaged in physical activity and carry out physical activity mainly while doing the job and walking. But those who are active meet weekly recommendations for duration of activity.

Key messages:

- Physical activity is one of the key health factors and one of the most effective ways of preventing chronic non-communicable diseases.
- There is a need of more public health interventions in order to promote recommended frequency, duration and different types of physical activity.

Impact of community gardens on the sustainability of lifestyles: baseline data of the JArDinS study

Marion Tharrey

M Tharrey[1], *M Perignon*[1], *P Scheromm*[2], *C Mejean*[1], *N Darmon*[1]
[1]MOISA, INRA, Montpellier, France
[2]INNOVATION, INRA, Montpellier, France
Contact: marion.tharrey@supagro.fr

Introduction:

Despite growing evidence for the multiple health benefits of community gardening, longitudinal studies based on quantitative data are needed. JArDinS is a quasi-experimental study aimed at assessing the impact of community garden participation in the adoption of more sustainable lifestyles.

Materials and **Methods:**

Gardeners starting gardening in a community garden in Montpellier (France) were recruited in 2018. Volunteers with no experience in community gardening and matched for age range, gender, household income and household composition were recruited in a control group. A recruitment goal of 80 participants per group was determined to detect a 30% increase in F&V supply in the gardeners group. Participant were issued with three tools: a Food Supply Dairy to collect data on monthly household's food supply, a triaxial accelerometer to measure physical activity and an online questionnaire on mental and social health, sensitivity to food waste, and connection with nature. Measures have been collected at baseline and will be repeated 12 months later. Data collected are examined conjointly to assess the sustainability of lifestyles in its social/health, environmental and economic dimensions. Change of outcomes after 1 year will be compared between the natural experiment and the control groups, to evaluate the effect of access to a community garden on the sustainability of lifestyles.

Results:

A final number of 77 participants per group were enrolled at baseline, which is 4% less the original recruitment goal. Baseline data for the natural experiment group and the control group are currently being analysed and will be presented.

Discussion:

This study will provide valuable information about the potential of community gardens to favor sustainable lifestyles, based on a robust quasi-experimental design allowing causality evaluation. Findings could help developing policies toward more sustainable urban planning favoring both human and environmental health.

Key messages:

- For the first time, the JArDinS study will allow testing, the impact of community gardens on the sustainability of lifestyles.
- Results will help orient urban planning decisions towards healthier options.

Smoking behavior and exposure to tobacco smoke in Split-Dalmatia County

Ivana Marasovic Šušnjara

I Marasovic Šušnjara[1]
[1]Public Health Institute of Split-Dalmatia County, Split, Croatia
Contact: ivana_ms@yahoo.com

Background:

Tobacco use is the leading preventable cause of death, which is why a number of measures to reduce its use are carried out in the world. That's why the aim of this study were to show the data on smoking behavior and the exposure to the tobacco smoke of the inhabitants of the Split-Dalmatia County, which represent the starting point in the creation of public health interventions

Methods:

Via European Health Survey 2014/2015 (EHIS) the data on the smoking behavior and exposure to tobacco smoke in the Split-Dalmatia County were colected. The targeted population was aged 15 and over. The survey included 267 inhabitants (141 men and 126 women) of the Split-Dalmatia County.

Results:

The overall sample shows that the daily smokers are 22.43% of the population, men 25.71%, and women 18.69%. Occasionally smokes 3.04% of the population (2.14% of men and 4.06% of women), while non-smokers are 74.52% of the population (77.23% of women and 72.1% of men). Tobacco products consumed are mostly cigarettes (97%). More than half (52.63 %) smokes more than 20 cigarettes a day. According to the survey results, more than half of the population (61.04%) has never or nearly never been exposed to indoor smoking, men rarely (56.03%) compared to women (66.1%). Less than one hour was exposed to 17.74% of the population (21.55% of men and 13.91% of women) and one hour and more 16.45% of the population (18.10 men and 15.65 women).

Conclusions:

Indicators of smoking behavior and exposure to tobacco smoke are somewhat more favorable to residents of the Split-Dalmatia County than in the total population of Croatia. Despite the measures taken for years in Croatia, these indicators are still unsatisfactory. Existing measures need to be re-examined and strengthened to overcome this important public health problem as successfully as possible.

Key messages:

- In order to reduce the prevalence of smoking and improve the health of its population, Croatia needs to strengthen and adopt additional policies on tobacco control.
- One of the measures would certainly be a ban on smoking in public places, which could, among other things, have a significant impact on denormalising smoking in the community.

The relationship between sleep quality and nutrition of medical school students in a city of Turkey

Erkan Pehlivan

E Pehlivan[1], *E Yalcin*[1], *B Firinci*[1]
[1]Inonu University, School of Medicine, Battalgazi, Malatya, Turkey
Contact: erkan.pehlivan@inonu.edu.tr

Background:

Students need quality sleep and regular feeding during an intensive training proces. The aim of this study was to determine the sleep quality of Faculty of Medicine students and whether there is a relationship between sleep quality and eating attitudes and habits.

Methods:

In this cross-sectional study; a face-to-face questionnaire was administered to 352 students who attending Inonu University Medical Faculty between January and March of 2019. The sample group is stratified according to class sizes (total 1665 students. The sleep quality and eating behaviors of students were questioned. For purpose, Pittsburgh Sleep Quality Index (PUKI, developed by Buysse et al,1989), and Eating Attitude Test (EAT,developed by Garner et al 1982) was used to assess quality and disorders. Kolmogorov Smirnov normal distribution test, Mann Whitney U and Kruskal Wallis test were used in analysis of the data.

Results:

The mean age of the students was 21.5 ± 2.5 and 54.3% were female and 45.7% were male and 25.0% smoked cigarette. 64.4% of the study group had normal body mass index. The median value of the PUKI (cut of point is 5.0 and under 5 is good) score by gender is similar with 6.0 (1.0-15.0). The median value of the PUKI score was 6.0 (1.0-16.0) in social media / internet users and 5.0 (1.0-13.0) in non-users. According to Internet / social media users before going to sleep, the difference is significant (p: 0.016). The difference between cigarette smoking and median value of PUKI was significant (p: 0.029). there was a difference between classes in favor of upper classes in terms of EAT values (p = 0,046). 12.2% of the students are at risk of Blumia and 10.8% are at risk of Anorexia. There was no significant but positive correlation between the PUKI and EAT (p = 0.074, r = 0.096).

Conclusions:

In general, the students' sleep quality and eating attitudes and habits were found close to the cut-off points accepted by the tests. But blumia and anorexia is significant. This study was supported by the Research Fund of the Inonu University (No. 1792)

Key messages:

- Social media / internet usage of students before going to sleep affects sleep quality significantly.
- Although 64.4% of the students have normal body mass index, eating disorders (bulumia and anorexia) risk are noteable.

Misconceptions, not evidence guide occupational physicians' decisions on legionellosis prevention

Matteo Riccò

M Riccò[1], *F Balzarini*[2], *AG Mezzoiuso*[2], *ME Colucci*[3], *W Catellani*[4], *L Veronesi*[4], *M Corradi*[3]
[1]Dipartimento di Sanità Pubblica, Azienda USL di Reggio Emilia, Reggio Emilia, Italy
[2]Scuola di Specializzazione in Igiene e Sanità Pubblica, Università, Milan, Italy

[3]Dipartimento di Medicina e Chirurgia, Università degli Studi di Parma, Parma, Italy
[4]Dipartimento di Sanità Pubblica, Azienda USL di Parma, Parma, Italy
Contact: mricco2000@gmail.com

Introduction:

Legionnaire's diseases (LD) is a significant cause of community-acquired pneumonia. An increasing number of cases has been linked with occupational exposures. The aim of this study was understanding knowledge, attitudes and practices of occupational physicians (OPh) towards LD.

Methods:

A questionnaire-based cross-sectional study (April 2019), collecting a convenience sample of OPh operating in the Parma Province. Knowledge status (KS), Risk Perception (RP), and actual participation to the LD risk assessment were assessed. Multivariate odds ratios (mOR) for factors associated with participation to the LD risk assessment were calculated by means of a binary logistic regression analysis.

Results:

80 OPh participated to the survey (76.9% participation rate; mean age 48.2±11.2 years): even though the majority of them assisted at least one enterprise at potentially high risk for LD (i.e. 41.4% retirement houses, 27.1% water treatment plants including spas and pools, 25.7% hospitals) only 42.9% had participated to the LD risk assessment. The majority of OPh did not acknowledge diabetes (52.9%), cancer (65.7%), alcoholism (77.1%) as risk factors for LD, while a large share of OPh did not recognize hospital (50.0%), retirement houses (48.6%), swimming pools (48.6%) and spas (35.7%) as high risk environments. Moreover, participants underestimated both actual frequency (>1000 cases/year) and severity (lethality 10-15%) of LD in Italy, and occupational RP was not coincidentally low (43.2%±20.3). Participants reporting better KS were more likely to participate to the risk assessment (mOR 4.82 95%CI 1.06-21.94), while RP was eventually unrelated with preventive practices.

Conclusions:

OPhs were diffusely affected by significant knowledge gaps on the actual risk factors for LD. Their misperceptions have the potential to negatively influence daily practice, impairing prevention of LD on the workplaces, and should be specifically targeted by information campaigns.

Key messages:

- Occupational Physicians were affected by significant knowledge gaps, particularly on individual and occupational risk factors for legionnaire disease.
- In order to better address the increasing threat of Legionnaire Disease, Occupational Physicians should be specifically targeted by information campaings.

Clear proceedings as workplace health promotion. Supervision and management tools in rural Uganda

Gaia Piccinni

G Piccinni[1,2,3], G Putoto[4]
[1]Service of Hygiene, Epidemiology and Public Health, Health Area of Brunico, Brunico, Italy
[2]School of Hygiene and preventive Medicine, University of Turin, Torino, Italy
[3]Doctors With Africa CUAMM, Padua, Italy
[4]Planning and Operational Research, Doctors With Africa CUAMM, Padua, Italy
Contact: gaia.ma@yahoo.it

Health centres and supervision teams in rural/poor settings in developing countries are affected by limited resources, uneasy reporting to higher level of power and unclear proceedings to filling the gaps. Inconsistency in supervising visits lead to mistrust. Supervisees react with resistance or indifference. Supervisors react behaving as policemen. In Uganda, Oyam Health District, february-august 2018, actions were taken in order to solve conflicts, sustain quality, improve interactions. Sharing the concept and the implementing process could inspire colleagues engaged in workplace health promotion.

Key points were informed by direct observations, talks with staffs, literature review, ugandan Ministry of Health official directives and tools, NGO's adaptations. Selected issues were discussed during two workshops held in april '18 involving all the concerned staff: 100 people. Agreement reached, based on a 3 (gap-act-resp) 5 (0-4 grading) algorithm, re-designed tools were able to reduce aléa during inspections, grade the gaps, guide actions and to address the appropriate level of responsability. User friendly reporting formats, database and unicode for linkage were designed ex novo. Information flow was agreed with the Health District Authorities.

After the learning period, staffs felt empowered about resolving gaps and less stressed advocating higher authorities. Conflicts lost harshness. Satisfaction was captured by a self-filled anonymous questionnaire in june 2018 (n = 80, 12 core questions, 0-4 likert scale, mean >3, SD < 1, median = 4, open sentences positives). Quality improvements of health care services were measured by the Ugandan Ministry of Health independently.

Unclear targets, shortage of means, ineffective communication flows reduce quality and trigger frustration. Sustaining transparency, organizing communication flows and proceedings, sourcing staff's experience could enhance success both in reaching targets and promoting relational health at workplace.

Key messages:

- Transparency, shared decisions, clear communication, awareness of the aims and mastership are able to reduce conflicts and misunderstandings, sustaining a healthier workplace relational environment.
- People spend 60 to 80% of their active time at workplace. Well designed tools, policies and information flows, could be effective health enhancer as well. Work style is a lifestyle.

Re-imagining risky health behaviour as salutogenic practice

Ruth Cross

R Cross[1]
[1]School of Health and Community Studies, Leeds Beckett University, Leeds, UK
Contact: r.m.cross@leedsbeckett.ac.uk

Background:

Much has been written about the problematic risky health practices that some young women in western cultures engage in defined as, for example, drinking alcohol to excess, smoking and taking drugs. Conversely the literature is more limited with regards to the meaning that young women attribute to such 'unhealthy' practices. Exploring and understanding meaning is important in order to design more effective health promotion interventions.

Methods:

This paper will present findings from 22 in-depth interviews with young women aged 18 - 14 years in post-compulsory education who were invited to talk about health and risk. Discourse analysis was used to explore the data drawing on feminist and governmentality perspectives.

Results:

The data presented complex constructions of risk taking in health drawing on intertwined discourses of moralism, healthy citizenship, idealised femininity and health as a gendered pursuit. However, the young women also constructed their 'unhealthy' practices in alternative, more agentic, resistant and philosophical ways.

Conclusions:

Based on these latter findings it is proposed that some risky health behaviours should be interpreted as salutogenic rather than pathogenic in nature. Subjective constructions of risky health practices as salutogenic should be taken into account in risk communication strategies and interventions in public health.

Key messages:

- Exploring and understanding meaning is important in order to design more effective health promotion interventions.
- Subjective constructions of risky health practices as salutogenic should be taken into account in risk communication strategies and interventions in public health.

The Comprehensive Community Engagement Framework for Health and Well-being

Pete Milos Venticich

HS Adnan[1], *PM Venticich*[1], *L Prevo*[1,2], *F Schneider*[1,3], *S Kremers*[1,2]
[1]Department of Health Promotion, Maastricht University, Maastricht, Netherlands
[2]Department of Health Promotion, NUTRIM, Maastricht University, Maastricht, Netherlands
[3]Department of Health Promotion, CAPHRI, Maastricht University, Maastricht, Netherlands
Contact: pventicich@gmail.com

Background:

Community engagement (CE) and empowerment are required to support the sustainability and effectiveness of actions to reach Agenda 2030. There is a need to guide CE for health and well-being to take action on important societal challenges such as the growing burden of non-communicable diseases (NCDs) and health inequities. The framework proposed in this study has been designed to assist professionals, practitioners and communities to effectively engage.

Methods:

A narrative review of existing grey literature, policy papers and models related to CE was performed. This guided the development of a systematic search strategy, performed by two researchers, which reviewed CE approaches and key influencing factors. The search strategy captured different terms used for CE.

Results:

A total of 27 studies of different types, from around the world, were identified for inclusion into the review. The study compiled a set of widely-used theories and approaches to CE. Key factors such as governance, trust, accessibility and sociocultural contextualisation were also identified as important for the success of CE initiatives. Subsequently, the Comprehensive Community Engagement Framework (CCEF) was developed. It combines theoretical and empirical principles, proven participatory actions and key factors to produce evidence-based health and well-being outcomes across different sectors and levels of society.

Conclusions:

This study has formed the basis of a forthcoming WHO report on CE. The CCEF enables the operationalisation of CE to guide for possible practical approaches to planning, initiating, sustaining and evaluating CE processes alongside the community. It can be used by the health sector as well as the non-health sectors to address health, well-being and broader societal challenges.

Key messages:

- The CCEF can be used to engage health and non-health stakeholders to tailor CE processes, increase impact of interventions and policies, building capacity and empowering communities.
- The proposed framework provides the first comprehensive guidance to conduct community engagement.

Patient education in the context of Parkinson disease cared for with deep brain stimulation

Marie Gaille

M Gaille[1], *Ms Lancelot*[1]
[1]SPHERE, CNRS, Paris, France
Contact: mariegaille@yahoo.fr

Background:

From the 1960 on, Western societies have developed patient education. In France, patient education is part of the public health Law since 2009. Research on patient education has developed in the field of social sciences and humanities in order to understand the social dynamics on which it is based, its intended implications and actual results. As patient education may contribute to an evolution of health care services, this research gives rise to a knowledge that is important to ground public health policies. Funded by IReSP, the present study is innovative as it explores the contemporary development of patient education in the field of Parkinson disease; analyses the teaching models that grounds patient education in this field; examines the implications of technological care (here, deep drain stimulation) in terms of transmitted knowledge and acquired skills.

Methods:

1. Review of literature.
2. Conceptual analysis of the teaching models (and tools) used in training sessions.
3. Ethnographic work (observations of training sessions; qualitative interviews with health professional and patients) - multi-centric perspective (Paris, Nantes, Toulouse).

Results:

- Historical reconstitution of the development of patient education in the context of Parkinson disease worldwide, with a focus on the French context, and its actors.
- Identification and examination of a variety of goals assigned to patient education.
- Identification and examination of the teaching models (and tools) used in training sessions.

Conclusions:

Patient education in the field of Parkinson disease shows a great variety of educational practices and of transmitted knowledge. The analysis of its teaching models (and tools) and of the place devoted to technological care in the training sessions show the necessity to better clarify the goals assigned to patient education (patient autonomy, patient observance, emergence of the expert patient).

Key messages:

- A clarification of the goals and teaching models of patient education is needed.
- A specific attention must be paid to patient education in the context of technological care.

Health Promotion: a multidisciplinary analysis of the factors affecting practices of professionals

Maria Assumpció Bou Monclús

MA Bou Monclús[1,10], *MT Casamitjà Sot*[2,10], *J Mallolas Jimenez*[3,10], *J Sunyer Serrat*[4,10], *S Mantas Jimenez*[5,10], *O Turró Garriga*[6,10], *N Ferrer Morell*[7,10], *L de la Peña Torres*[8,10], *MT Mir Coll*[9,10]

[8]Health Promotion, Official Association of Nursing, Girona, Spain
[9]Family and Community Medicine, Catalan Institute of Health, Olot, Spain
[10]Group of Professionals for Health Promotion, Girona, Spain
Contact: assumpcio.bou@gmail.com

Background:

The coordination and degree of involvement of health professionals is essential for the success of the implementation of health promotion programmes.

We belong to a regional multidisciplinary research group on Health Promotion. The aim of this study was to better ascertain how to empower the health professionals and general population.

Methods:

A qualitative study was conducted among doctors, pharmacists, nurses, psychologists and veterinarians between March 2017 and December 2018. Six focus groups, with 32 women and 20 men purposively selected, were formed to determine the barriers and facilitators for the implementation of Health Promotion in their daily work and to assess their recommendations. Theoretical saturation was reached, and validity of the study was ensured by triangulation.

Results:

The main barriers were: lack of training on Health Promotion which led to demotivation and distrust of own capacities, work overloaded and not valued neither by colleagues nor institutions, weak coordination between care and professional levels, inexistence of common guidelines, a health model based on disease and not addressing the social determinants of health, and, finally, legislation not being adequate. Volunteering, motivation and commitment of professionals were the most outstanding facilitators. Participants highlighted the need for all health professionals to be trained and to improve the budget for Health Promotion. They proposed that all health-related university degrees should incorporate a subject on Health Promotion. Likewise, better coordination between care and different professional levels is required, and the existing legislation should be enhanced for better promoting health.

Conclusions:

The Health in All Policies approach should be provided with enough resources and consider all health disciplines. Further multidisciplinary studies are needed to make the system more people-centred.

Key messages:

- More training of health professionals' skills and improved budget are required to implement health in all policies.
- Health Promotion policies need coordination and multi-disciplinary guidelines.

Health relay students' goals, training and assessment: result from a French national consensus

Laurent Gerbaud

L Gerbaud[1,2]*, E Born*[1]*, M Gourbeuil*[1]*, A Perrève*[1]*, Bureau ADSSU*[3]
[1]Service de Santé Universitaire, Université Clermont Auvergne, Clermont-Ferrand, France
[2]Service de santé publique, Université Clermont Auvergne, CHU Clermont-Ferrand, CNRS, SIGMA Clermont, Institut Pascal, Clermont-Ferrand, France
[3]ADSSU, Maison des Universités, Paris, France
Contact: lgerbaud@chu-clermontferrand.fr

Issue:

Health relay students (HRS) is one of the prevention policy rapidly increasing for the French students. It is mainly based on peer effects, peer to peer communication, but the state of play show very various practices.

Description of the problem:

The variety of practices may imply heterogeneity, and actions that are too disparate. In October 2016, the national association of directors of Health Services for Students (SSU) decided to make a formal consensus process (based on single scripting strategies developed in parallel by 10 to 20 people) involving 61 persons (physician, nurses, prevention officer, members of prevention associations) from 29 French universities and based on three axes: goals; training and assessment.

Results:

No disagreement was left. The goals must be validated by the SSU, as it is the unit that is able to link students 'associations wishes and health policy objectives. This need a constant dialogue with the university board, students associations, local authorities and health administration. The HRS are also important to help to know the students practices, notably thanks to their presence on social networks. Institutional policies for HRS must be consistent to the goals, and HRS must be managed by specific prevention officers. Training always associate health education topics and health prevention knowledge. It may be more or less intensive according to the goals, but need the help of association of health prevention and a validation by the SSU. HRS must be diverse, in genders and type of studies. The training must encourage HRS autonomy and creativity in their actions, while accepting to respect the University health policy. Creativity means also to open any way of communication wanted by HRS, such as social networks.

Assessment is based on lean management, HRS satisfaction and University satisfaction (institution as well as teachers, administrative workers and students). HRS empowerment is perhaps the main criteria of assessment.

Key messages:

- Health relay students policies are very varied and need a consensual framework under the control of health services for students.
- Training must associate health education and prevention objectives, develop students' empowerment.

Age-related and seasonal change in serum osmolarity and water intake in a healthy population

Tomofumi Nishikawa

T Nishikawa[1,2]*, N Miyamatsu*[1,3]*, A Higashiyama*[1,4]*, Y Nishida*[1]*, Y Kubota*[1,5]*, T Hirata*[1,6]*, D Sugiyama*[1,7]*, K Kuwabara*[1,8]*, Y Miyamoto*[1,4]*, T Okamura*[1,8]
[1]Foundation for Biomedical Research and Innovation, Kobe, Japan
[2]Faculty of Health Science, Kyoto Koka Women's University, Kyoto, Japan
[3]Department of Clinical Nursing, Shiga University of Medical Science, Otsu, Japan
[4]Department of Preventive Medicine and Epidemiologic Informat, National Cerebral and Cardiovascular Center, Osaka, Japan
[5]Department of Environmental and Preventive Medicine, Hyogo College of Medicine, Nishinomiya, Japan
[6]Department of Preventive Medicine and Epidemiology, Tohoku M, Tohoku University, Sendai, Japan
[7]Faculty of Nursing And Medical Care, Keio University, Tokyo, Japan
[8]Department of Preventive Medicine and Public Health, Keio University, Tokyo, Japan
Contact: dogsbow@gmail.com

Background and aim:

Few studies have clarified the seasonal and age-related change of serum osmolarity and water intake, which is thought to be associated with heat stroke and ischemic stroke. We investigated the association between them in a healthy population.

Methods:

We conducted a cross-sectional study using database from Kobe Orthopedic and Biomedical Epidemiologic (KOBE) Study. Among 1138 healthy Japanese participants in the baseline survey, 1010 (women 704 and men 306) participants were eligible for the present study. Daily non-alcohol drink (NAD) intake was estimated according to food frequency questionnaire. Alcohol beverage and water in the meal or soup were excluded from the counting. Serum osmolarity (Osm/L) was calculated by Worthley's formula: 2 (serum sodium (mEq/L)) + (blood urea nitrogen (mg/dL))/2.8 + (glucose (mg/dL))/18. The seasons the surveys were conducted were categorized into 4 groups, March-May (Spring), June-August (Summer), September-November (Autumn), and December-February (Winter). The association between serum osmolarity and daily NAD intake was analyzed using linear regression models.

Results:

The seasonal change was observed in the serum osmolarity and daily NAD intake; serum osmolarity increased in spring and summer and daily NAD intake increased in summer. The serum osmolarity increased by aging in any seasons, while daily water intake didn't. There was no significant association observed between serum osmolarity and the daily NAD intake, even after adjusting for sex, age, and season.

Conclusions:

Serum osmolarity showed seasonal and age-related changes, but the serum osmolarity in subjects who had the daily habit of high NAD intake was not necessarily low.

Key messages:

- Serum osmolarity increased by aging and in spring and summer.
- Serum osmolarity was not associated with non-alcohol drink intake.

The Turkish adaptation of the family and nutrition and physical activity (abfa-tr) screening tool

Merve Çolak

H Ikiisik[1]*, E Ekici*[2]*, H Ankaralı*[1]*, G Manav*[3]*, M Yetim*[2]*, EH Kozan*[2]
[1]Faculty of Medicine, Istanbul Medeniyet University, Üsküdar, Istanbul, Turkey
[2]Faculty of Health Sciences, Uskudar University, Üsküdar, Istanbul, Turkey
[3]Faculty of Health Sciences, Sıtkı Koçman University, Muğla, Turkey
Contact: merve.yetim@uskudar.edu.tr

Background:

Assessing the dieatary and physical activity state of the family is important in determining the causes of obesity in the child. The aim of this study is to adapt The Family Nutrition and

Physical Activity Screening Tool (FNPA) to Turkish and evaluate its reliability and validity.

Methods:

In this methodological research, mixed probabilistic sampling methods were used. The sample size was not calculated and it was aimed to reach all of the 1126 students and families in the three primary schools with different socioeconomic status (high, medium, low) in Uskudar, Istanbul. A total of 727 students' and their families' data were collected. Research data were collected by a two-part questionnaire. Survey forms were composed of an introductory information form and the Turkish version of the (FNPA). The low total score on the scale means high-risk family environment and behavior, and the high total score means a more positive family environment and behavior. Prior to the implementation of the scale in the field, a pilot application was made.

Results:

The Cronbach alpha coefficient for the internal consistency of the scale was 0.724. The test-retest reliability coefficient of the scale had a medium to very high level ranged from 0.422 to 0.925. The Kaiser-Meyer-Olkin test result of the 20 questions in the scale was found to be appropriate as 0.771. To evaluate the validity of the content, relationships between the scale score and the answers given the questions about the eating behaviors of the family which were not included in the scale. When these relationships were evaluated, the mean scores of those who had regular breakfast were significantly higher (P = 0.001).

Conclusions:

The study shows that the ABFA-TR scale is a valid and reliable measurement tool for Turkish population.

Key messages:

- It is likely that home environments and parental behaviors with interchangeable risk factors for obesity and overweight may alleviate or aggravate the potential risk of obesity.
- The development and use of measurement tools related to the family environment as an element of obesogenic environment are among the important steps taken to fight obesity.

Measuring health literacy: performance-based versus perception-based measures

Chiara Lorini

C Lorini[1], *V Lastrucci*[1], *G Bonaccorsi*[1]
[1]University of Florence, Department of Health Science, Firenze, Italy
Contact: chiara.lorini@unifi.it

Background:

Many performance-based or perception-based measurement tools of health literacy (HL) have been developed. The aim of this study is to compare the results of performance-based versus perception-based measures of HL in a population-based sample in Florence (Italy).

Methods:

223 subjects were interviewed. To measure HL, HLS-EU-Q16 (perception-based measure of general HL) and NVS (performance-based measure of functional HL) were used. Sociodemographic characteristics were collected.

Results:

The majority of the subjects had high school (36%) or university (44%) degree and gets to the end of the month quite or very easily with financial resources available (69%). Considering age classes, 22% was 18-45, 26% 46-55, 34% 56-65, 18% 66-70 year-old. According to HLS-EU-Q16, 11.8% had inadequate, 55.5% problematic and 33% sufficient HL; considering NVS, 11.7% had high likelihood of limited HL, 28.7% possibility of limited HL, 59.6% adequate HL.

The percentage of people with low HL was higher for HLS-EU-Q16 than for NVS in each category of age class, educational level, and financial resources. For both measures, the percentage of people with low HL increased with age, becoming more similar for older people: for HLS-EU-Q16, from 59.2% for 18-45 to 78.4% for >65 years old; for NVS, from 20% for 18-45 to 67.5% for >65 years old. Similar results were observed for educational level and financial resources: for both tests, the percentage of people with low HL increased with the decreasing of educational level or financial resources; for the worst situations (less than high school diploma or having not enough financial resources), the percentage of people with low HL become similar comparing the two tests.

Conclusions:

Perception-based measure of general HL and performance-based measure of functional HL investigate different aspects, but in the worst situations (older people, low educational level and not enough financial resources) they tend to produce the same result.

Key messages:

- Perception-based measure of general HL and performance-based measure of functional HL investigate different aspects.
- In the worst situations (older people, low educational level and not enough financial resources) they tend to produce the same result.

Self-regulation, norms and alcohol consequences: study on university freshman from four EU countries

Ondrej Kalina

M Bacikova-Sleskova[1]
[1]Department of Educational Psychology & Health Psychology, Pavol Jozef Safarik University in Kosice, Kosice, Slovakia
Contact: ondrej.kalina@upjs.sk

High alcohol consumption is undoubtedly one of the most serious health and public issues across Europe. In addition to other licit and illicit drugs, it causes more than 4% of all deaths in the EU for those aged between 25 and 39. Among protective factors the self-regulation (SR) has been frequently associated with lower levels of risky drinking. On the other hand, overestimated descriptive normative beliefs (NB) may serve as a powerful source of social influence on personal alcohol use. Both SR and NB may be especially important during the period when young adults leave their families and may feel less external control and more freedom to use alcohol what may lead to serious health consequences. Therefore this study explores the associations among SR and NB in relations to alcohol use and negative alcohol consequences.

Data among 2671 first-year college students were collected in 2011. Students from the Czech Republic (n = 357), Hungary (n = 783), Lithuania (n = 928) and Slovakia (603) who filled in the AUDIT test, Self-Regulation Questionnaire and questions regarding NB. Regression models (separately for each country) were computed to test whether different level of SR influences the relationship between NB and alcohol use and between alcohol use and negative consequences.

Overestimated NB were positively associated with risky drinking in all countries and similarly alcohol use increased the level of negative consequences. Moreover, in predicting risk drinking and alcohol consequences, a moderation effect of SR was confirmed as associations among NB and alcohol use and among alcohol use and negative consequences were stronger among those students with lower SR.

The protective effect of SR on risky alcohol and consequences together with social norms approach may potentially improve the intervention accuracy and make it a promising target for intervention among young adults.

Key messages:

- Students from all explored countries highly overestimated the actual alcohol use what was significantly associated with theirs higher alcohol consumption.
- Those students who overestimated the actual alcohol consumption but had higher levels of self-regulation were less likely to drink or report negative alcohol consequences than their peers.

Building a social marketing Strategy to reduce alcohol-related harm in France

Guillemette Quatremère

M Hochet[1], *G Quatremère*[1], *R Andler*[1], *C Cogordan*[1], *V Nguyen Thanh*[1]
[1]Addictions Unit, Santé Publique France, Saint-Maurice, France
Contact: guillemette.quatremere@santepubliquefrance.fr

Background:

Alcohol use ranks among the top three risk factors in France, leading to about 40 000 deaths annually. French health authorities wished to renew the public health message about alcohol consumption and build a social marketing Strategy to lower the social and health consequences of alcohol consumption in France.

Objectives:

Two main steps were followed: 1) gathering a group of experts to provide up-to-date low-risk drinking guidelines, 2) building, testing and implementing a social marketing Strategy based on this expertise.

Results:

In 2017, the group of experts established low-risk drinking Guidelines based on both scientific evidence and socially acceptable risks for the French population. They suggested to increase awareness on alcohol-related harm as well as on the new Guidelines. In 2018, a social marketing Strategy was set up by Santé publique France, the French national public health Agency. Qualitative and quantitative pretests allowed to develop understandable and potentially effective communication materials consisting of the following message: ''To protect your health, no more than 2 alcoholic drinks a day, and not every day''. A web-based brief intervention to assess a person's alcohol consumption was developed, based on a previous tool whose effectiveness had been demonstrated. In 2019, the Campaign was launched: health professionals were informed at first, followed by a national mass media Campaign that was broadcasted for 3 weeks, targeting the general population (TV, radio, press, the Internet).

Conclusions:

It is the first time in France that such a global Strategy is set up to promote an alcohol harm reduction message. A robust evaluation is in progress but this structured approach seems feasible and reproducible abroad.

Key messages:

- In France, an alcohol harm reduction Strategy has been built up and implemented, based on scientifically-established Guidelines.
- The social marketing campaign is rigorously evaluated to assess its impact and portability.

Perceptions of health professionnals in a French social marketing campaign against smoking

Guillemette Quatremère

G Quatremère[1], *R Guignard*[1], *R Andler*[1], *A Pasquereau*[1], *V Nguyen Thanh*[1]
[1]Addictions Unit, Santé Publique France, Saint-Maurice, France
Contact: guillemette.quatremere@santepubliquefrance.fr

Background:

In 2016, Santé publique France, the French national public health agency, launched a social marketing campaign aiming at triggering quit attempts among smokers: ''MoisSansTabac'', inspired by the British ''Stoptober''. Every year, smokers are encouraged to quit smoking for 30 days in November, health professionals are encouraged to participate in the campaign to support them. In 2018, pharmacists received a poster (''Here, we help smokers stop smoking'') and self-help kits to distribute to smokers. Measuring the perceptions of health professionals is crucial to have a complete overview of the impact of the campaign and to identify ways of improvement.

Methods:

A qualitative evaluation of the 2018 edition has been performed to collect the perceptions of general practitioners (GPs) and pharmacists about the intervention and services provided through the campaign (quitline, website, mobile app, self-help kit). In December 2018, semi-directed interviews were conducted with 24 GPs and 24 pharmacists. A diversity of profiles was ensured (professional settings, geographic area, age, gender, smoking status). A content analysis was performed.

Results:

While health professionals had generally poor awareness of the intervention, their opinions were divided depending on their professions. GPs did not feel sufficiently associated nor did they understand how they could specifically participate during this one-month event while they support smokers all year long. Pharmacists were pleased to be involved: they felt recognized in their role as health counselors although their participation remained low. Help cessation services were positively perceived. Some health professionals expected to have a more clearly defined role and to get evidence on the effectiveness of the intervention.

Conclusions:

To improve the acceptability and effectiveness of ''MoisSansTabac'', there is a need to rethink the place of health professionals and how to communicate with them about the campaign.

Key messages:

- 'Mois Sans Tabac' is a social marketing intervention which is considered acceptable by general practitioners and pharmacists but improvements are necessary.
- Health professionals could get more involved in the campaign if their role was better defined.

Free access to nicotine substitutes and e-cigarette for tobacco cessation: STOP a pilot intervention

Fabienne El-Khoury

M Héron[1], *M Melchior*[1], *F El-Khoury*[1]
[1]INSERM UMRS 1136,Institut Pierre Louis d'Epidémiologie et de Santé Publique, Paris, France
Contact: fabienne.khoury@gmail.com

Background:

Smoking rates in France are high, and present a substantial socio-economic gradient. Smokers with low socio-economic position (SEP) may be more dependent on nicotine, and have more financial difficulties to buy nicotine substitutes. Tailored approaches are therefore needed.

Methods:

STOP (Sevrage Tabagique à l'aide d'Outils dédiés selon la Préférence) is an ongoing pilot study, examining the acceptability of a smoking cessation intervention. Smokers with low SEP are recruited in six healthcare centres in Greater Paris area by health professionals and are offered substitute(s) of their choice for 4 weeks. Participants can choose between different types of nicotine substitutes (NS; patches, inhalers, etc.) and/or an e-cigarette delivered free of charge. The acceptability of this approach is examined in patients and doctors, using a mixed-method approach.

Results:

So far, 30 smokers have been included in our study, 20% chose e-cigarettes, 36% chose NS, 36% chose both, and 2 participants (8%) chose neither. More than half of participants quit smoking (66%) at one week after inclusion, with 11 reporting tobacco abstinence out of 16 participants followed for 4 weeks. The average number of cigarettes smoked decreased from 15(sd = 10) at inclusion to 8.5 (sd = 5) among those who didn't quit at four week. In qualitative interviews, one of the facilitators highlighted by health professionals was the perceived ''met need'' of smokers with low SEP when given free quitting aids without upfront-payment. One of the reported obstacles is the difficulty in scheduling consecutive follow-up meetings in short time.

Discussion:

It is feasible to implement a smoking cessation programme aimed at smokers with low SEP, and embedded in the healthcare system. If proven effective, this intervention could contribute to decreasing social inequalities with regard to tobacco use. Recruitment in a randomised controlled multicentre trial based on this pilot study will start at the end of 2019.

Key messages:

- It is feasible to put in place a smoking cessation intervention among socially-disadvantaged in healthcare centres.
- Free access to nicotine substitutes and e-cigarettes could be a promising smoking cessation intervention among smokers with low socio-economic position.

Self-Reported Muscle Strength As A Strategy For The Prevention Of Non-Communicable Diseases

Frank Rincon

F Rincon[1], *J Peña*[1], *C Yanez*[1], *C Castillo*[1], *A Téllez*[2]
[1]IMED, Fundación Universitaria del Area Andina, Bogota, Colombia
[2]Cultura Física, Deporte y Recreación, Universidad Santo Tomas, Tunja, Colombia
Contact: frankrinconv@gmail.com

Background:

Muscle strength is considered as a health indicator and an independent predictor of future disease. For this reason, the evaluation of this component in the young population is recognised as a fundamental strategy for the prevention of non-communicable diseases. Field tests are the techniques most commonly used to evaluate muscle strength. However, an alternative method that could be applied in epidemiological studies is self-report questionnaires. The aim of this research was to evaluate the ability of a self-report questionnaire to correctly rank the levels of muscle strength in college students.

Methods:

A cross-sectional study was developed in 135 students from the Areandina University in Bogota, Colombia. For the evaluation of muscle strength, two tests were applied. The first was the application of the handgrip protocol using an adjustable handle Digital Grip Strength Dynamometer. The second was the application of protocols to a maximum repetition in 6 different exercises. For the assessment of self-perceived strength, the third question of the International Scale Fitness Questionnaire (IFIS) was applied. The IFIS response options are presented on a Likert scale with five possible answers: ''very poor'', ''poor'', ''average'', ''good'' or ''very good''. An analysis of variance (ANOVA) was applied to evaluate the ability of the IFIS questionnaire to rank muscle strength levels correctly.

Results:

Overall, 70.3% of the participants were men, and 29.7% were women. The results of the field tests and the self-perception of muscle strength were significantly higher in the male group than in the female group ($P < 0.001$). Students who reported having good or very good muscle strength in the questionnaire had a better result in the field tests compared to those who reported average, poor or very poor muscle strength levels ($P < 0.005$).

Conclusions:

The IFIS questionnaire was able to rank real muscle strength in university students correctly.

Key messages:

- The IFIS questionnaire is a valid alternative to detect students with a potential risk of chronic non-communicable diseases.
- The epidemiology surveillance systems in Colombia should include the application of self-report questionnaires that evaluate potential risk factors.

Effectiveness of Mois sans tabac 2016, a French social marketing campaign against smoking

Romain Guignard

R Guignard[1], *J-B Richard*[1], *R Andler*[1], *A Pasquereau*[1], *G Quatremère*[1], *V Nguyen-Thanh*[1]
[1]Health Promotion and Prevention Department, Santé Publique France, Saint-Maurice, France
Contact: romain.guignard@santepubliquefrance.fr

Background:

In October 2016, Santé publique France, the National Public Health Agency, launched a social marketing campaign aiming at triggering quit attempts among smokers: ''Mois sans tabac'', inspired by the English 'Stoptober'. This campaign sets smokers the objective of being smokefree for one month, in November. It combines a national mass-media communication with provision of cessation help services (quitline, website, mobile application, self-help kit) and local actions, in connection with the health regional agencies. The study aims at evaluating the effectiveness of this intervention.

Methods:

The effectiveness evaluation is based on a specific analysis of the 2017 Health Barometer, a random survey representative of the population living in metropolitan France conducted between January and July 2017 on a sample of 25,319 individuals aged 18-75 years-old. The participation rate was 48.5%. Multivariate logistic regressions allowed testing the association between recall of the campaign and quit attempts (QA) in the last quarter of 2016, adjusted for sociodemographic confounders ($N = 6{,}341$). Respondents who attempted to quit were contacted at one-year for a follow-up.

Results:

Nearly one in six daily smokers (15.9% [14.9-17.1]) reported making a 24-hour QA in the last quarter of 2016, and 18.4% [15.5-21.3] of them reported that it was related to Mois sans tabac, which represents approximately 380,000 QA [310,000-440,000] related to the operation. Among smokers who made a QA, 31% have been abstinent for at least 30 days [27%-34%] and 18% [15%-21%] reported they did not smoke anymore in 2017. Recall of Mois sans tabac was associated with QA in the last quarter of 2016 ($aOR = 1.3$ [1.1-1.6], $p < 0.01$) and with cessation in 2017 ($aOR = 2.4$ [1.4-4.2], $p < 0.01$), and odds-ratios increased with frequency of exposure and number of sources of information.

Conclusions:

These results show that the first edition of Mois sans tabac was successful in triggering quit attempts among smokers.

Key messages:

- Mass-media campaigns for smoking cessation, combined with provision of help services and local actions, can be effective for triggering quit attempts.
- Importing foreign social marketing programs can be effective.

The association between eating vegetables at start of meal and dental caries among Japanese children

Kanade Ito

K Ito[1], *A Isumi*[2,3], *S Doi*[2], *M Ochi*[4], *T Fujiwara*[2]
[1]Department of Oral Care for Systemic Health Support, Tokyo Medical and Dental University, Tokyo-to, Japan
[2]Department of Global Health Promotion, Tokyo Medical and Dental University, Tokyo-to, Japan
[3]Japan Society for the Promotion of Science, Tokyo-to, Japan
[4]National Institute of Mental Health, National Center of Neurology and Psychiatry, Tokyo-to, Japan
Contact: kanade-i@umin.ac.jp

Background:

Dental caries is still serious problem among Japanese children. Previous studies suggested that higher consumption of vegetables prevent dental caries. Eating order habit, such as eating vegetables at start of meal, called ''Vege-first'', may increase the amount of vegetable consumption, and in turn, prevent dental caries. However, no published studies have examined the impact of ''Vege-first'' habit on dental caries. The aim of this study to investigate the association between ''Vege-first'' and dental caries among Japanese children.

Methods:

We used the 2015 cross-sectional data from the Adachi Child Health Impact of Living Difficulty (A-CHILD) study, a population-based study of all first-grade students in Adachi City, Tokyo, Japan. The number of DMFT (decayed, missed due to decay, and filled teeth) was used as an outcome. Poisson regression analyses were applied to determine the independent association between ‘‘Vege-first’’ habit and the number of DMFT after controlling for the effects from child's sex, parents' marital status, socioeconomic status, and frequency of tooth brushing, drinking sweet beverages, and snacking.

Results:

Of 3,689 valid Japanese children participants, 38.2% had DMFT and 11.6% were having the ‘‘Vege-first’’ habit. The number of DMFT decreased linearly with ‘‘Vege-first’’ habit ($p < 0.001$). After controlled for covariates, the number of DMFT was still significantly and independently decreased with ‘‘Vege-first’’ habit (prevalence $\text{ratio} = 0.89$ (95% confidential interval [0.81-0.98])).

Conclusions:

This study showed that having the ‘‘Vege-first’’ habit was associated with dental caries even accounting for socio-economic status, dental health behavior, and dietary habits. Health policy introducing ‘‘Vege-first’’ habit may be effective to prevent pediatric dental caries.

Key messages:

- Eating habit which vegetables at start of meal called ‘‘Vege-first’’ may increase the amount of vegetable consumption and possibly reduce dental caries.
- The habituation of Vege-first was likely to reduce child's dental caries even accounting for socioeconomic status, dental health behavior and dietary habits.

Barriers and facilitators of health behavior engagement in ultra-Orthodox Jewish women in Israel

Donna Zwas

E Leiter[1], *A Finkelstein*[3,4,5], *K Greenberg*[1], *O Keidar*[1,2], *M Donchin*[1,2], *DR Zwas*[1]
[1]Cardiology, Linda Joy Pollin Cardiovascular Wellness Center for Women at Hadassah University Medical Center, Jerusalem, Israel
[2]Braun School of Public Health and Community Medicine, Hebrew University and Hadassah Medical Center, Jerusalem, Israel
[3]Hebrew University of Jerusalem, Jerusalem, Israel
[4]The David Yelin Academic College of Education, Jerusalem, Israel
[5]Machon Tal, The Jerusalem College of Technology, Jerusalem, Israel
Contact: donnaz@hadassah.org.il

Background:

The ultra-Orthodox Jewish (UOJ) community is a primarily low socio-economic, culturally insular minority sub-sect in Israel. Compared with the general population, UOJ women report higher rates of diabetes and overweight, lower physical activity rates, and have lower breast cancer survival rates. Research in this sub-sect is limited. Identifying the facilitators and barriers to health behavior engagement would facilitate public health intervention design in this population.

Methods:

This study describes UOJ women's barriers and facilitators to engagement in targeted health behaviors (i.e. health nutrition, physical activity), identified through mixed methods analysis. Qualitative and quantitative analyses of interviews ($N = 5$), focus groups (5, including 35 women), and questionnaires ($N = 239$) identified barriers to engaging in preventive health behaviors and intervention preferences.

Results:

Most of the barriers identified (financial and time limitations, personal preferences, lack of education/awareness, and family-related obstacles) are similar to those reported by women from the general population. Cultural aspects such as women's role in the home, religious restrictions, and modesty were also identified as barriers to health behavior engagement, comparable to women from other insular communities.

Conclusions:

Utilizing a mixed methods approach in identifying barriers and facilitators informed intervention development and improved cultural tailoring, potentially serving as a model for intervention design with additional UOJ communities as well as other difficult to access, low socio-economic, culturally insular populations.

Key messages:

- This is the first study identifying facilitators and barriers to UOJ women's health behavior engagement.
- Findings can inform intervention design in difficult to access, culturally insular populations.

Important factors to ensure wellbeing in a whole-school setting – a photovoice study

Jo Ese

J Ese[1], *J Flobakk*[2], *C Castellan*[2], *C Ihlebaek*[2,1]
[1]Faculty of Business, Languages and Social Sciences, Østfold University College, Halden, Norway
[2]Department of Public Health Science, Norwegian University of Life Sciences, Aas, Norway
Contact: jo.ese@hiof.no

Background:

The whole-school approach focuses on promoting health and wellbeing for pupils, employees, and parents. In Norway, several schools are now developing such an approach and opening the school premises for community activities. The aim of this study was to investigate what pupils, employees and parents themselves experience as important factors to ensure wellbeing in a whole-school setting. More knowledge about such factors as perceived by the users could give important information in order to ensure health promotion in other schools wanting to implement a whole-school approach.

Methods:

The participatory method Photovoice was used. Seven pupils, six employees, and four parents at Alvimhaugen Primary School, Norway photographed what they perceived as factors generating wellbeing at the school premises. The school is located in an area with challenges related to living conditions. The pictures were used as basis for six focus group discussions by the participants. All interviews were audiotaped, transcribed and analysed using Malterud's Systematic Text Condensation and Drew & Guillemins framework for image analysis. The results were discussed within the framework of Sense of Coherence (SOC).

Results:

The factors that emerged as important for wellbeing among all stakeholders were interconnected. Important factors were the built and natural environment, activities before/during/after school hours, and organisational characteristics. Further, these factors were associated with a sense of security, belonging, social support and manageability expressed by the stakeholders.

Conclusions:

The factors identified are all known to be central in strengthening SOC. These factors are therefore important for promoting health, not only in pupils but also in employees and parents. The whole-school approach could contribute to address complex public health issues and wellbeing, and might be especially important in schools in deprived areas.

Key messages:

- The built and natural environment, activities before/during/after school hours, and organisational characteristics are all important aspects to ensure wellbeing in a whole-school approach.
- The whole-school approach could contribute to promote wellbeing, and might be especially important in schools in deprived areas.

Implementation process of social prescribing to improve primary care patients' health and well-being

Sonia Dias

S Dias[1], *C Figueiredo*[2], *A Coelho*[2], *L Hoffmeister*[3], *A Gama*[1]
[1]Escola Nacional de Saúde Pública, Centro de Investigação em Saúde Pública, Universidade NOVA de Lisboa, Lisbon, Portugal
[2]Unidade de Saúde Familiar da Baixa, ACES Lisboa Central, Lisbon, Portugal

[3]Escola Nacional de Saúde Pública, Universidade NOVA de Lisboa, Lisbon, Portugal
Contact: smfdias@yahoo.com

Social prescribing (SP) is an innovative approach to tackle social determinants of health. It enables general practitioners (GPs) to address non-medical causes of ill-health by linking primary care patients with non-medical community sources of support. Despite convincing results from punctual evaluations, comprehensive evaluation of SP is needed to provide guidance on what works and evidence on its impact.

A SP pilot-project started in 2018 in a primary care service in Lisbon. Its implementation process and outcomes are being evaluated through a longitudinal mixed-method evaluation study assessing patients' wellbeing, quality of life, anxiety and depression in key stages of the intervention and stakeholders' perspectives on facilitators/barriers to the intervention implementation.

GPs refer patients to a social worker of the service, who defines with the patient the individual intervention plan using community resources. Initially, GPs and social workers were trained on SP, a network of community partners was built, SP information was distributed to patients, a referral online platform was created and a baseline study is being conducted. In the 1st semester, 130 patients were referred: 39.2% were ≥65 years old, 70.8% were female, 45.4% had foreign nationality. Over two thirds were referred for multiple reasons mostly social isolation, immigration/social integration, mental health, sedentary lifestyle, access to social benefits and employment/skills training.

The project has enabling to support patients with multiple complex psychosocial needs. Regular meetings between GPs and partners have improving collaboration and patients' supervision. The participatory approach and training emerged as facilitators of the intervention. Yet, the increased burden on social workers due to growing referral profile and some stakeholders' scepticism toward SP need to be addressed. The triangulation of sources, methods and data provide evidence on the intervention impact and scalability.

Key messages:

- The social prescribing intervention has been effective in tackling multiple social determinants of health.
- Intervention evaluation is being key to identify facilitators and opportunities for scale up.

"Health Party" intervention on genetic testing for ethnic minority women: study protocol

Valencia Kabeya

V Kabeya[1], S Puthussery[1], A Furmanski[2]
[1]Institute for Health Research, University of Bedfordshire, Luton, UK
[2]School of Life Sciences, University of Bedfordshire, Luton, UK
Contact: valencia.kabeya@study.beds.ac.uk

Background:

Culturally appropriate interventions are needed to improve the uptake of genetic counselling and testing among ethnically diverse communities. This study aims to assess the feasibility and preliminary effectiveness of a "Health Party" intervention to increase awareness, knowledge and uptake of genetic testing for breast and ovarian cancer among ethnic minority women in the UK.

Methods:

The "Health Party" intervention will include an educational session in a party setting. Participants will be taught by professionals about genetic testing and how to access genetic testing services in the UK National Health Service. We will recruit a sample of 60 women aged 18 years and over from key ethnic minority groups in the UK (Black African, Black Caribbean, Indian, Pakistani, Bangladeshi) and will conduct four community based sessions, each with about 15 participants. The outcomes will primarily relate to recruitment and attrition rates, data collection, study resources and intervention delivery. A quantitative pre-post evaluation with measurements before, shortly after, and at 6 months following the intervention will be conducted to assess the preliminary effectiveness on awareness, knowledge and uptake of genetic testing. We will use three way mixed analysis of variance (MANOVA) to analyse changes pre- and post- intervention. The fidelity of the intervention including facilitation strategies, quality of delivery and participant response will be assessed.

Conclusions:

Findings will establish the feasibility of the intervention and will provide insights into its effectiveness to increase the awareness, knowledge and uptake of genetic testing for breast and ovarian cancer among women from ethnic minority groups in the UK.

Impact: Depending on its feasibility and effectiveness, the intervention can be used to help women from ethnic minority groups to make informed choices about genetic testing and improve early diagnosis and treatment of breast and ovarian cancer.

Key messages:

- "Health Party" may be a feasible intervention for ethnic minority women in the UK.
- "Health Party" intervention may increase awareness, knowledge and uptake of services.

Lifestyle, environmental exposures and male fertility in healthy young men in North Italy

Claudia Zani

C Zani[1], D Zani[2], F Donato[1], M Marullo[1], GCV Viola[1], S Lorenzetti[3], L Montano[4]
[1]Department of Medical and Surgical Specialties Radiological, University of Brescia, Brescia, Italy
[2]Unit of Urology, Hospital ''Città di Brescia'', Brescia, Italy
[3]Department of Food Safety, Nutrition and Veterinary Public Health, Italian National Institute of Health (ISS), Rome, Italy
[4]Andrology Unit and Service of Lifestyle Medicine in UroAndro, ASL Salerno ''Oliveto Citra Hospital, Salerno, Italy
Contact: claudia.zani@unibs.it

Background:

Human semen quality is affected by metabolic, lifestyle and environmental factors. We planned a randomized controlled trial to evaluate the effects of lifestyle changes on semen quality in healthy young men living in Italian highly polluted areas. We present here some preliminary baseline data on the association between lifestyle and semen quality.

Methods:

150 non-smokers, non-alcohol drinkers and non-obese young healthy men, aged 18-22 years, have been assigned to an intervention or control group according to a 1:1 randomization plan. The intervention group follows a 4-month nutritional pathway based on a Mediterranean dietary pattern and receives suggestions on practice of physical activity. All subjects undergo urologic examination, measurement of weight, height and abdominal circumference, an interview on lifestyle variables, and provide blood and semen samples in fasting conditions, at the enrollment and at the end of the intervention and follow-up (after 8 months). Adherence to Mediterranean diet is assessed using the "PREvención con DIeta MEDiterránea" (PREDIMED) tool, and physical activity using the "International Physical Activity Questionnaire" (IPAQ). Automated sperm analysis for all semen parameters is performed on the SQA-V GOLD.

Results:

The data of 101 subjects living in a highly industrialized area in North Italy (mean±SD: age: 20.3±1.2 years, BMI: 22.3±2.2) were analyzed. The sperm cell concentration was higher in subjects with IPAQ score > median than those with lower values (68.3±48.6 vs 63.7±47.0 106/mL). Total percent motility was higher in subjects with abdominal circumference < median (50.7±13.6 vs 41.2±18.8, p = 0.004), in subjects with IPAQ score > median (48.2±16.8 vs 44.2±16.8), and in subjects with PREDIMED score > 7 (47.6±18.8 vs 45.0±15.0).

Conclusions:

These preliminary data suggest that semen quality is associated with abdominal fat and physical activity in healthy young men.

Key messages:

- The semen quality is a sensitive marker of the health status and is predictive of disease occurrence.
- Our study suggests that semen quality is associated with lifestyle aspects in healthy young men.

Developing the Turkish version of the exercise benefits/barriers for the elderly scale

Saime Erol

S Erol[1]*, O Erdem*[1]*, H Koç*[1]*, F Çetin*[1]*, N Erkek*[1]
[1]Nurisng Department, Public Health Nursing, Marmara University Faculty of Health Sciences, Istanbul, Turkey
Contact: saimeerol@hotmail.com

Objective:

The aim of this study was develop the Turkish version of the exercise benefits and barriers scale for elderly people.

Methods:

The study was carried out with the methodological research design with a total of N = 300 individuals living in a nursing home (n = 134) and applying to the Family Health Center (n = 131) between October 2017 and May 2018. The study included subjects aged 65 years and older who had no dementia, communication or physical disability. The item pool of the scale consisted of 36 items. Items were structured in five-likert form. Expert opinions of eleven individuals were received for Content Validity Index (CVI). The data of the study were collected with 26-question socio-demographic characteristics form, the Mini Mental Test and the Exercise Benefits/Barriers Scale for the Elderly (EBBSE). Approval and consents were obtained from the relevant Ethics Committee, from the healthcare facility and participants. For the validity and reliability; CVI, exploratory factor analysis (EFA), confirmatory factor analysis (CFA) Hotelling's T2, paired sample t test have been carried out.

Results:

The mean age of the subjects was 72.44±5.94 years. Scale's CVI was 90. The factor analysis demonstrated that the scale included three sub-dimensions of 18 items in Physical and Psychological Benefits of Exercise, 2 items in Social Benefits of Exercise and 8 items inExercise Barriers accounting for 55.36 % of the total variance of the scale. Cronbach Alpha internal consistency coefficients of the scale was .84. All of the four fit indices obtained in the CFA had desirable magnitudes (RMR = .05;RMSEA = ,07;NFI = .81;CFI = .87), indicating a good fit between the model and the data. The item total score correlations ranged from .40 to .69. The scale's test-retest correlation was .99.

Conclusions:

EBBSE is a valid and reliable scale that can be used to evaluate benefits and barriers perceptions in physical activity practices.

Key messages:

- Developed EBBSE can be used to determine the perceptions of exercise for elderly.
- Developed EBBSE can be used to change barrier perceptions of exercise.

Effectiveness of the universal substance use prevention program on alcohol consumption among adults

Marta Dobrowolska Kulanová

M Dobrowolska-Kulanová[1]*, M Štefaňáková*[2]*, O Orosová*[1]
[1]Department of Educational Psychology and Psychology of Health, PJ Safarik University in Košice, Košice, Slovakia
[2]Department of Psychology, PJ Safarik University in Košice, Košice, Slovakia
Contact: mata.kulanova@gmail.com

Background:

Universal substance use prevention program (PUNAV) is a 24-hour course primarily aimed at developing the competencies of future teachers and prevention trainers. One of the key strategies in the PUNAV is correcting the misperceptions and this way changing normative beliefs about risky behaviour, which, when overestimated, are a predictor of risky behaviour.

Objective:

To explore whether the participation in PUNAV has an effect on alcohol use of future teachers and whether this relationship is mediated by descriptive normative belief regarding alcohol use while considering gender as a possible moderator of these processes.

Methods:

The sample consisted of university students from Slovakia; n = 277, 78% women, Mage = 22.23, SD = 2.12. The PUNAV effect was explored within an experimental design. The potential pre-test effect was rejected based on a comparison within the experimental groups and within the control groups (using Solomon model of four groups). The bootstrapping analysis was used to test for moderated mediation according to gender using SPSS Process macro and linear regressions.

Results:

The results showed that participation in the PUNAV has a direct effect on alcohol consumption (AUDIT subscore) only among men (b = -1.88, 95%CI -2.9- -.8). An indirect effect through the descriptive normative beliefs about alcohol use (effect size: -.25, BootCI: -.46 - -.07) was found when the whole sample was taken into account. Participation in PUNAV was found to be related to normative beliefs about alcohol use ($\beta = -.32$, p<.001) and these were related to alcohol consumption ($\beta = .20$, p<.001).

Conclusions:

Participation in the PUNAV, which aims primarily to develop the competencies of future teachers proved useful for prevention showing a significant effect with respect to their alcohol consumption.

Acknowledgement: This work was supported by grant projects APVV-0253-11 and APVV-15-0662.

Key messages:

- Well-designed and databased prevention programs can affect risk behaviour among adult population.
- The importance of normative beliefs as a major strategy to achieve effectiveness of prevention programs has been constantly supported by empirical evidence.

Obesity Prevalence in Alabama: Trends from 2011 to 2017 and Evaluation of a State Obesity Program

Zihan Dong

Z Dong[1]*, SW Pan*[1]
[1]Department of Health and Environmental Science, Xi'an Jiaotong-Liverpool University, Suzhou, China
Contact: jane.zhd1509@gmail.com

Background:

Alabama, one of the southeastern states in the US, suffers from a heavy burden of obesity. In 2014, Alabama launched a state program named 'ALProHealth', aiming to prevent and reduce obesity prevalence. The objective of this study is to evaluate the potential impact of the ALProHealth Program on the prevalence of obesity in Alabama from 2014 to 2017.

Methods:

Data for this study come from the Behavioral Risk Factor Surveillance System (BRFSS). An interrupted time series design was employed. The state obesity prevalence trend for the pre-program period (2011-2014) was estimated and compared with the post-program period (2015-2017). Statistical analyses were conducted using segmented linear regression. Indiana was chosen as the control group in this study.

Results:

The obesity prevalence in Alabama significantly increased from 31.8% in 2011 to 36.2% in 2017, increasing by 0.81% on average each year (95% CI: 0.47 to 1.15, p = 0.002). Before the ALProHealth Program, the obesity prevalence increased by 0.59% (p = 0.11) and 0.32% (p = 0.34) in both Alabama and Indiana respectively, though it is not statistically significant. After the program implementation, the slope of obesity prevalence increased by 0.43 (p = 0.45) and 0.03 (p = 0.96) in Alabama and Indiana respectively, though change is not significant. When comparing Alabama and Indiana, the rate of slope change is higher in Alabama (0.73) compared with Indiana (0.093), indicating the rate of slope change in obesity prevalence increased faster in Alabama than Indiana.

Conclusions:

To sum up, the study found no evidence that the ALProHealth Program contributed to the decrease of obesity prevalence in Alabama. One possible reason is that there was low program coverage. Future studies should examine the potential effectiveness of other programs using a similar conceptual model as ALProHealth Program.

Key messages:

- In 2014, Alabama launched a state program named 'ALProHealth', aiming to prevent and reduce obesity prevalence.
- The study found no evidence that the ALProHealth Program contributed to the statewide decrease of obesity prevalence in Alabama, which may attribute to low program coverage.

The relationship between participation to social activities, life satisfaction, isolation on aged

Saime Erol

O Erdem[1], S Erol[1], A Aydoğan[1], B Subaşı[1], L Kılıç[1]
[1]Nurisng Department, Public Health Nursing, Marmara University Faculty of Health Sciences, Istanbul, Turkey
Contact: saimeerol@hotmail.com

Objective:

This study was conducted to determine the relationship between the participation of people living in the nursing homes to social activities and their life satisfaction, social isolation and loneliness.

Methods:

The study was performed between January 2017 and April 2018 in three nursing homes using the cross-sectional research design. The study population consisted of 310 elderly people in total, 118 women, 192 men, who were over 65 years of age and had no mental and communication problems. Ninety percent of the population was reached. The data were collected by using a questionnaire, Standardized Mini Mental Test, Satisfaction with Life Scale (SWLS), Social Isolation Scale (SIS) and Loneliness Scale for Elderly People (LSEP). Descriptive statistics, Mann-Whitney U test, Kruskal-Wallis variance analysis and Spearman correlation analysis were used in data analysis.

Results:

The mean age of the elderly subjects was 74.10 ± 7.57 years, and 61.9% were male and 38.1% were female. Elderly subjects' SWLS and LSEP scores were below the median, and their SIS score was above the median value. Elderly people without disabilities, who can meet their own needs, do not feel alone, stay in the healthcare facility of their own accord, are satisfied with the services healthcare facility and with life, do sports, go to cinema and theater in their free time and go out more often had high SWLS median values and low SIS and LSEP values (p < 0,05). Examining scale correlations, a moderate and negative correlation between SWLS and SIS (r = -,59; p = ,000) a highly significant and negative correlation between SWLS and LSEP (r = -,70; p = ,000) and a positive, statistically moderately significant correlation between SIS and LSEP (r = , 65; p = , 00) were found.

Conclusions:

Life satisfaction increases and social isolation and loneliness decreases when elderly people living in nursing homes participate in social activities.

Key messages:

- Loneliness of elderly individuals can be reduced by increasing participation in social activities.
- Social isolation of elderly individuals can be reduced by increasing participation in social activities.

Opticourses: promoting healthier food purchases at no additional cost in low-income households

Marion Tharrey

M Tharrey[1], M Perignon[1], C Dubois[2], H Gaigi[3], N Darmon[1]
[1]UMR MOISA, INRA, Montpellier, France
[2]CD, Trophis, Marseille, France
[3]HG, Conseil, Marseille, France
Contact: marion.tharrey@supagro.fr

Introduction:

Healthy diets are generally more expensive than unhealthy diets, explaining why socially disadvantaged individuals perceive food prices as a barrier to improve their diets. It is thus crucial to develop strategies enabling the achievement of good nutritional quality with a low budget, taking into account actual beliefs and expectations of the target population. A co-construction approach is thus recommended, involving participants at each step of the intervention to maximize its impact.

Methods:

The ''Opticourses'' program was launched in 2010 with a feasibility study, followed by an intervention research in 2012-2014, in order to develop and evaluate a prevention program aiming at improving the nutritional quality of food purchases at no additional cost in a socioeconomically disadvantaged population. In order to implement activities tailored to the target population, participants were involved in the development of the protocol and the tools of the intervention and evaluation processes.

Results:

Opticourses's workshops (8 to 12 participants) include different activities displayed in four 2h sessions around real food purchases of participants, and games and exchanges aimed at promoting food and food choices of good nutritional quality for their price. The intervention research showed improvements in food purchasing behaviors of Opticourses participants. A transferability phase was conducted in 2015-2017. Since 2017, Opticourses is spreading in several regions of France, through training of professionals, in particular the courses organized by the Health Education Regional Committee (CRES) in the South of France.

Discussion:

Bringing an original, concrete, co-constructed and scientifically based response to an everyday life problem is the main strength of the program. One important risk of failure for such prevention program is the underestimation of the requirements of the intervention research, in terms of time and human and budgetary resources.

Key messages:

- From a research point of view, getting access to new food purchasing data will allow a continuous refinement and innovation in the improvement of the diet for people with budgetary constraints.
- By focusing on food purchasing, a familiar activity that most adults feel able to handle, the Opticourses program is engaging and pragmatic, in accordance with health promotion principles.

Transition to health democracy in France: occupational therapy for population-based interventions

Sophie Albuquerque

S Albuquerque[1], L Farias[2]
[1]Occupational Therapy, School of Rehabilitation Sciences, Aix-Marseille University of Medical and Health Sciences, Marseille, France
[2]Occupational therapy Division, Department of Neurobiology, Karolinska Institutet, Huddinge, Sweden
Contact: sophie.albuquerque@univ-amu.fr

Background:

Health promotion stands as a core value of occupational therapy, a client-centred healthcare profession that achieves this goal by enhancing individuals' ability to engage in activities that they want to, need to, or are expected to do. Yet, occupational therapists in France have not been working in alliance with Public Health funding or programs in the community to reduce possible illnesses leading to chronic conditions and hospitalizations. There is a need to discuss how these professionals can collaborate with Public Health initiatives to move beyond individual interventions and address population-based needs. This study explores occupational therapists opportunities to develop health promotion practices in France.

Methods:

A participatory action research was conducted with six co-participants using occupational justice-based frameworks and the French National Public Health report on Health Promotion as a ground for discussion which extended over 3 months. Qualitative content analysis and Kemmis' practice architecture theory was used to understand how practices are shaped by discursive, economic and socio-political circumstances.

Results:

Preliminary results show that occupational justice-based reasoning enables practitioners to shift from an individual to a population needs focus. Yet, the lack of education for this type of practices is evident. The findings highlight prerequisites that need to be fulfilled in order to apply an occupational justice-based approach within health promotion initiatives.

Conclusions:

Working on community settings allows practitioners to comprehend the complex interactions between individuals and context. Public Health field provides an interface between society requirements and populations needs in which occupational therapist could enact health promoting interventions. The practice in this field is emerging and therefore it is relevant to discuss the competencies that should be included within occupational therapy education.

Key messages:

- A healthcare system that does not consider its population's contextual situation is a failing system. France's welfare transformation requires all professionals to develop community-based initiatives.
- The findings will support the development of the first guidelines for health promotion occupational therapy practices in France.

Schoolchildren's participation in health promotion process

Ruta Maceinaite

R Maceinaite[1], *G Šurkienė*[1], *R Sketerskienė*[1]
[1]Faculty of Medicine, Institute of Health Science, Vilnius University Faculty of Medicine, Public Health Institute, Vilnius, Lithuania
Contact: ruta.maceinaite@gmail.com

Background:

Health promotion (HP) process enables people to increase control over their own health. Schools offers ideal setting for HP interventions as most children spend a large part of time there. The pupils should be involved in this process. Information about schoolchildren's participation in HP process is a key when planning measures to improve the situation. The shortage of information about students' participation in this process leads to the aim of study - to determine schoolchildren's' participation in HP process.

Methods:

Cross-sectional study was conducted in 2018. 906 schoolchildren aged 14-19 from 29 schools in Lithuania were surveyed by anonymous questionnaire (response rate 80.5%). Logistic regression models with 95% of CI were used for the data analysis. Statistical significance level was $p \leq 0.05$.

Results:

More than half of respondents (51.4% (95% CI: 48.2; 54.7)) participated in HP process. Participation was significantly related to residence (OR = 2.47 (95% CI: 1.80; 3.39)) and grade (OR = 1.39 (95% CI: 1.06; 1.82)). Participation in health promoting events (57.7% (95% CI: 53.2; 62.1)), assistance in organizing events (33.5% (95% CI: 29.3; 37.9)) - were the most common ways of schoolchildren's participation. 35.3% of pupils (95% CI: 32.3; 38.5) evaluated their participation as good or very good. 68.7% of schoolchildren (95% CI: 65.6; 71.6)) wanted to participate in HP process more actively. Girls were more likely to want to participate in HP process more actively than boys (OR = 2.08 (95% CI: 1.56; 2.78)), children who lived in countryside were more likely to want to participate in HP process more actively than pupils who lived in city (OR = 1.42 (95% CI: 1.02; 1.99)).

Conclusions:

Only half of schoolchildren participated in HP process. The majority of pupils would like to participate in HP process more actively, so it is very important for the school to create the right conditions and encourage schoolchildren to participate in HP process.

Key messages:

- The participation of schoolchildren in health promotion process is insufficient.
- The majority of pupils would like to know more about health promotion process.

Is medical ionizing radiation negligible or neglected? How to interact with patients?

Isabelle Nicoulet

I Nicoulet[1]
[1]Bureau des Expositions en Milieu Médical, Autorité de Sureté Nucléaire, Montrouge, France
Contact: isabelle.nicoulet@sfr.fr

Issue:

Medical exposure is in France, the first source of artificial exposure of populations to ionizing radiation (IR). The use of ionizing radiation in diagnosis, (CT scan) is steadily increasing. With IR, nothing is visible, nothing is lost, everything is cumulative and transformed. How to explain it to patients and how to answer their questions? How, in this area, can patients become empowered?

The radiologists have already produced information materials for patients. Explaining the different types of exams is easy, explaining the dose is more complex; doses are not expressed with the same units. In addition, since the organs do not all have the same sensitivity to ionizing radiation, the addition of doses delivered does not always make sense. The comparison of doses delivered with the natural exposure to ionizing radiation makes it understandable. Specific awareness campaigns such as 'for lumbago radio, this is not always the right scenario' were launched.

One of the main rule of radioprotection is the justification of the act in relation to the expected benefit. Both general practitioners and patients can influence the decision by asking simple questions. An awareness campaign on this theme is planned by HERCA (European HEad of Radiation protection Competent Authorities) in Europe in November 2019.

It aims to reduce inappropriate exams by breaking habits. It is aimed mainly to general practitioners.

Results:

The French Nuclear Safety Authority will decline this campaign for both general practitioners and patients. This campaign is based on the most common questions such as:

- If I have already made a diagnosis, what is the added value of a radiological examination?
- Why should I have another radiological examination?
- Why refer my patient for an X-ray or CT if another examination can be done that does not use ionizing radiation?
- Why is it important to ask if pregnancy is a possibility?

Lessons:

Illustrative documents will be presented at the congress

Key messages:

- Risks related to medical exposure to ionizing radiation are not sufficiently explained.
- A European campaign of recognized authorities and the involvement of patients should help reinforce the messages of the French campaign.

Analysing local public health action plans: development of a tool for the French CLoterreS Study

Yann Le Bodo

Y Le Bodo[1], *R Fonteneau*[1], *C Harpet*[2,3], *H Hudebine*[4], *F Jabot*[1,3], *W Sherlaw*[1,3], *E Breton*[1,3]
[1]Department of Human and Social Sciences, EHESP School of Public Health, Rennes, France
[2]Department of Environmental and Occupational Health, EHESP School of Public Health, Rennes, France
[3]Arènes Research Unit, UMR CNRS 6051, Rennes, France
[4]LABERS Research Unit, Université de Bretagne Occidentale (UBO), Brest, France
Contact: yann.lebodo@ehesp.fr

Background:

The potential contribution of local authorities to prevention and health promotion is well recognized. In France, since 2009, Local Health Contracts (LHCs) are mobilising Regional Health Agencies, local elected officials and stakeholders to intervene in 4 areas: health promotion, prevention, health care and social care. LHCs remain poorly documented policy instruments.

Methods:

As part of the CLoterreS study, a multidimensional coding tool was developed and tested by two coders to explore the place of prevention and health promotion in LHCs. Its development was based on the WHO conceptual framework for action on the social determinants of health and the Self-assessment tool for the evaluation of essential public health operations in the WHO European Region. Preliminary results concern a random sample of 17 LHCs from as many French regions selected among the 165 LHCs signed between 2015 and March 2018.

Results:

On average, the LHCs featured 26 action forms (AF) (min: 5; max: 56). In a LHC, the average proportion of AF addressing either the social determinants of health, living circumstances or other determinants targeted by health protection, promotion or primary prevention interventions (SDoH-HPP-P1) was 79% while 44% of the AF address secondary/tertiary prevention, social care or the organization of health care and services. Among the SDoH-HPP-P1 themes (double coding permitted): psychosocial life circumstances were addressed in the 17 LHCs and concerned, on average, 31% of their AF; material living circumstances were addressed to a lesser extent (16 LHCs, 13%); other key themes include environmental health (12, 14%), mental health (16, 12%), alcohol abuse (15, 11%), drug use (14, 11%), smoking (13, 9%), physical activity (13, 12%), healthy eating (12, 12%).

Conclusions:

This work confirms that LHCs are instruments with prevention and health promotion at their core. Explanation of the differing investments in this area across our sample will be further explored.

Key messages:

- Local Health Contracts are promising instruments to address locally a broad range of health determinants.
- The CLoterreS analytical tool has proven effective in capturing multiple themes and shedding light on differences between Local Health Contracts' action plans.

Facebook Intervention To Improve Physical Activity Level Among Youth

Jovana Todorovic

J Todorovic[1], *Z Terzic-Supic*[1], *P Piperac*[2], *Z Stamenkovic*[1], *M Santric-Milicevic*[1], *B Djikanovic*[1]
[1]Institute of Social Medicine, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[2]Department of Humanities, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
Contact: jovana.todorovic@med.bg.ac.rs

Background:

Physical activity level decreases during the transition from late adolescence to young adulthood. Social media are nowadays widely used and part of many people's daily routines and the interventions on these websites have the possibilities to be integrated into those routines without becoming a burden. The aim of this study was to assess physical activity level among medical students and to assess the possibilities of using social media intervention with an aim to improve physical activity among them.

Methods:

Prospective study was conducted during October of 2016 at the Faculty of Medicine, University of Belgrade, Serbia. The study included 375 first and fifth-year students. At the baseline, students filled in the questionnaire regarding social and lifestyle characteristics as well as their physical activity. Physical activity was assessed using the International Physical Activity Questionnaire (IPAQ). After completing the questionnaire, students were asked to join a Facebook discussion group. The intervention consisted of motivation for physical activity through motivational pictures, texts, and discussions. The second assessment was done after one month. Based on the reported physical activity level students were divided into two groups: sufficient (>600MET-minutes/week) and insufficient physical activity ($\leq$600 MET-minutes/week).

Results:

Total of 85.4% of students were sufficiently active at the baseline, while 90.4% were sufficiently active after one month. Multivariate logistic regression analysis showed that students who were part of the Facebook group (OR: 3.51, 95% CI: 1.46-8.43) and students who had sufficient physical activity at the baseline (OR: 5.44, 95% CI: 2.44-12.13) had a higher likelihood to be sufficiently active after one month.

Conclusions:

Social media can be used for interventions targeting lifestyle change among young adults and activities on these websites can be adjusted to meet the needs of the target population.

Key messages:

- Intervention on social media could lead to lifestyle change.
- Interventions on social media could be adjusted to fit the target population.

Children self-reports and Parent proxy reports of physical activity and sedentary behaviour

Marija Jevtic

S Sumonja[1], *M Jevtic*[2,3]
[1]College of Vocational Studies in Subotica, Subotica, Serbia
[2]University of Novi Sad, Faculty of Medicine, Novi Sad, Serbia
[3]Institute of Public Health of Vojvodina, Novi Sad, Serbia
Contact: marija.jevtic@uns.ac.rs

Background:

Aim of this study was to determine agreement between parent proxy reports and children self-reports of physical activities and sedentary behaviour.

Methods:

The sample included 7-10 year-old children and their parents (n = 188) in a local community in Northern Serbia. Data were collected by questionnaires designed to assess context-specific measures of children's physical activity (outside play, organized sports) and sedentary behavior (TV viewing, using computer, playing electronic games). Children and their parents completed questionnaires separately. Agreement between children's and parent̀s responses was calculated with Cohen's kappa. Differences in parent̀s and childreǹs responses in relation to gender, grade and BMI were analyzed using $\chi 2$ test. Values $p < 0.05$ were considered statistically significant.

Results:

Level of agreement between parents' and children's reports ranged from poor for variable TV viewing before going to school ($\kappa = 0.21$; p = 0.04) to substantial for variable physical activity before going to school ($\kappa = 0.74$; p = 0.00). Girls were more likely than boys to agree with parents about time spent playing on the computer after school ($\chi 2 = 11.23$;p = 0.01). Overweight and obese children tended to report more time in TV viewing than their parents ($\chi 2 = 26.4$;p = 0.01).

Conclusions:

There are differences in reports of physical activities and sedentary behaviour between 7 to 10 year-old children and their parents The lowest level of agreement found for variable TV viewing indicates low awareness and control of this screen-based sedentary behaviour.

Key messages:

- Differences in parents' and children's reports of children's physical activities and sedentary behaviour are confirmed.
- It should be taken into consideration in studies which use self-reports or proxy reports for assessing children's physical activities and sedentary behaviour.

Factors promoting health empowerment of young people: a qualitative pre-interventional study

Marie Corneloup

M Corneloup[1,2], I Millot[2], N Ponthier[2], A Peteuil[2]
[1]UFR des Sciences de Santé, Université de Bourgogne, Dijon, France
[2]Instance Régionale d'Education et de Promotion de la Santé de Bourgogne-Franch-Comté, Dijon, France
Contact: mariecorneloup@hotmail.com

Background:

Angata, an intervention research project led by the regional instance of health education and promotion (Ireps) of Burgundy-Franche-Comté, aims to strengthening the autonomy and decision-making ability of vulnerable youth regarding their health. It is implemented in several facilities. The goal is to improve well-being and quality of life of young people benefiting from socio-educational measures by working with them and the professionals in their living environments. The objective of the study presented was to analyze the factors promoting health empowerment of young people, prior to this intervention, in the Employment Integration Facility (Epide) of Belfort.

Methods:

Interviews were conducted with 8 young people and 13 professionals to explore their representations regarding well-being, nutritional health (eating habits, nutrition, physical activity), self-esteem and physical appearance. The determinants of health, lifestyles and organization in the living environment as well as the biographical pathways of young people were also collected.

Results:

The Epide, structured on a military model, welcomes young people out-of-school, without qualifications and with complex life courses. The Epide can be seen as a functional community whose whole effort is dedicated to the goal of young volunteers leaving for a job or professional training. The support provided by educators (professional social or former military) is focused on building skills and restoration of self-esteem. Critical consciousness develops over time spent within the structure. The factors promoting empowerment within this strict framework are numerous, but young people's participation in the decisions taken within the structure remains at the solicitation stage.

Conclusions:

The framework provided at the Epide allows an environment conducive to the process of individual empowerment. These leverage can be mobilized to reinforce health empowerment of youth during the Angata project.

Key messages:

- An empowering educational environment, even strict, can foster the health empowerment of young people subject to vulnerabilities.
- The allowed level of participation remains an important factor to consider in order to fully promote health empowerment of young people.

Physical Activity Patterns of Primary School Teachers in a District in Istanbul, Turkey

Pinar Ay

A Surmen[1], P Ay[2], S Hidiroglu[2], M Karavus[2]
[1]Noncommunicable Disease, Ministry of Health, Yozgat, Turkey
[2]Public Health Department, Marmara University,School of Medicine, Istanbul, Turkey
Contact: npay@marmara.edu.tr

Background:

Physical inactivity (PI) is determined as the fourth leading risk factor for global mortality. Insufficient physical activity is prevalent in Turkey; approximately 4 in 10 adults are physically inactive and have less than 150 minutes of moderate activity per week. The objective of this study was to assess the prevalence of PI and the factors associated with it among primary school teachers in a district in Istanbul, Turkey.

Methods:

This was a cross-sectional study conducted in a district in Istanbul, Turkey. Sample size was calculated as 434 assuming a PI prevalence of 70% with a 95% confidence level, margin of error of 0.05 and a design effect of 2. Twenty out of 39 schools were selected randomly. PI was assessed through using International Physical Activity Questionnaire short form. Logistic regression analysis was used to determine the variables associated with PI.

Results:

A total of 345 teachers participated in the study (response rate: 79.5%). Among the participants the mean age was 45.6± 8.3 and %74.1 were women. PI prevalence was 49.2% (95%CI: 43.6%-54.7%). PI was significantly associated with having chronic disease (OR: 1.8, 95%CI:1.0-3.0), having children (OR: 2.9, 95%CI:1.5-5.7), using motor vehicles for transportation (OR:4.1, 95%CI:1.5-11.0) and using elevators (OR:4.4, 95%CI:1.7-11.4). Among women, PI was significantly associated with having children (OR: 10.3, %95CI:1.2-87.1) and using elevators (OR: 8.4, 95%CI: 2.3-30.8).

Conclusions:

Approximately half of the teachers were physically inactive. As having children is an important determinant of PI, we need to adopt appropriate conditions so that parents, particularly women can engage in physical activity together with their children. Active transportation and use of elevators should be encouraged. Special attention should be paid to adults having chronic diseases.

Key messages:

- PI is highly prevalent among school teachers, particularly among the ones who have chronic diseases.
- Strategies supporting parents especially women to engage in physical activity together with their children, encouraging active transportation and use of elevators should be implemented.

Appropriate approaches for improving health promotion literacy in adolescents – a systematic review

Silvia Florescu

S Florescu[1,2], C Mihaescu Pintia[1,2], C Sasu[1,2], M Ciutan[1,2], SG Scintee[1,2], R Sfetcu[3], C Vladescu[1,2]
[1]NSPHMPD, National School of Public Health, Management and Professional Development Bucharest, Bucharest, Romania
[2]PHEBRC_JBI_AG_R, Public Health Evidence Based Romanian Centre: A Joanna Briggs Institute Affiliated Group, Bucharest, Romania
[3]Spiru Haret University, Faculty of Psychology and Educational Sciences, Bucharest, Romania
Contact: florescu.silvia@gmail.com

Background:

Adolescents are exposed to various risks for their health: substance use, Internet overuse, video game addiction, unhealthy diet (reduced intake of fruits and vegetables, fast food culture), low physical activity, overweight, stress, violence, unsafe sexual behaviours, self-medication. Health literacy is defined as the knowledge, motivation and competence to access, understand, appraise and apply right information to make decisions in terms of healthcare, disease prevention and health promotion. Despite the advancement of theoretical models, many national and international health promotion programs, the percentage of unhealthy behaviours still persist in young age. Objective: Current review proposes to assess the implementation and effectiveness of various interventions in order to identify possible success or failure factors.

Methods:

Comprehensive Systematic review was performed. After three steps data searching (in PubMed, SCOPUS, Cochrane, PsycINFO, Google Scholar) and critical appraisal, 63 studies out of 739 were fully retrieved.

Results:

Implementation aspects as intervention types (single or combined targeted risk factors), type of audience (students, parents, school staff, communities), settings (home, school or outdoor), type of organization (face to face, groups, online), professional or peer-led, communication type (written materials as brochures, posters or videoconferencing) or effectiveness measures were extracted and synthesized. Important features of context such as funding, European or government programs were used for clustering the studies.

Conclusions:

Health literacy interventions in adolescents need the involvement of education staff and parents participation. Health literacy for adolescents has to take into account cultural context, language, psychological features of each age; either digital or non-digital interventions cannot elude face to face communication between adolescents and their parents, academics or peers.

Key messages:

- Health literacy school-based interventions are effective but the content for adolescents audience should rely on guidelines provided by interdisciplinary teams of experts.
- Health Literacy interventions in adolescents should be age-appropriate and do-not-harm precautions must always be taken in order to avoid prejudices, body-image or self-esteem concerns.

Improving participation of hard-to-reach older people in diet interventions: the INVITE strategy

Aurélie Bocquier

A Bocquier[1,2,3], C Dubois[4], P Verger[1,2,3], N Darmon[5], - INVITE study group[6]
[1]Aix Marseille Univ, IRD, AP-HM, SSA, Vitrome, Marseille, France
[2]IHU-Méditerranée Infection, Marseille, France
[3]ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France
[4]Trophis, Les Pennes Mirabeau, France
[5]MOISA, INRA, CIHEAM-IAMM, CIRAD, Montpellier SupAgro,Univ Montpellier,Campus Inra-SupAgro de la Gaillarde, Montpellier, France
[6]INVITE Study Group, Marseille, France
Contact: aurelie.bocquier@inserm.fr

Background:

A lot of behavioural interventions promoting healthy eating and physical activity are focusing older people, but, among them, individuals from low socioeconomic status and/or experiencing social isolation participate less. The aim of the present study was to design, pilot and perform a formative evaluation of an active recruitment strategy called 'INVITE'. This strategy aimed to improve participation of hard-to-reach older people in existing collective workshops combining diet and physical activities dedicated to older people.

Methods:

We co-constructed this strategy, based on results from a literature review, qualitative interviews with older people and professionals using the Behaviour Change Wheel framework as a guide. INVITE includes 5 steps: i) identification of socially deprived/isolated people aged 60-85 years in retirement fund databases; ii) postal invitation letter; iii) phone call; iv) home visit by a social worker. The formative evaluation used questionnaires (closed and open-ended questions) completed by 2 social workers in April 2019.

Results:

Among the 54 older people selected in the databases, 29 could be reached by phone. Among these 29 persons, 25 reported being interested by the collective workshops; 17 refused the home visit (main reasons: not available during the workshops period, current health problems); 12 accepted the home visit, but only 10 could be visited at home (one was ill; one cancelled the visit). Nine out of these 10 persons accepted to participate to the workshops. The main motivating factors were that workshops were: free; perceived as friendly; and as an opportunity to "go out" and to receive diet counselling to improve diet quality with no additional cost.

Conclusions:

The INVITE strategy was perceived positively but adjustments are needed to improve home visits acceptation rate (e.g., by revising the criteria used to identify people in the databases). We will now evaluate the attendance rate to the collective workshop.

Key messages:

- The INVITE strategy was designed to improve participation of hard-to-reach older people in combined diet and physical activity collective workshops.
- This strategy was perceived positively by most older people contacted and both social workers.

Measuring health promotion in a sports club setting: a modified Delphi study

Anne Vuillemin

S Johnson[1], A Vuillemin[1], S Geidne[2], S Kokko[3], J Epstein[4], A Van Hoye[4]
[1]Université Côte d'Azur, LAMHESS, Nice, France
[2]Örebro University, School of Health Sciences, Division of Sport Science, Örebro, Sweden
[3]University of Jyväskylä, Research Center for Health Promotion, Faculty of Sport and Health Sciences, Jyväskylä, Finland
[4]University of Lorraine, APEMAC, Nancy, France
Contact: anne.vuillemin@univ-cotedazur.fr

Background:

The settings-based approach has become an increasing focus in health promotion since the World Health Organization's 1986 Ottawa Charter. Schools and cities have implemented this approach, but development within sports clubs is limited. Thus, an internationally validated measurement of health promotion within this setting is lacking.

Methods:

A modified Delphi study was completed to develop an international evaluation tool grounded in the settings-based approach. Expert panelists from academia, sports and health sectors were invited to participate in 3 online rounds. Items were generated or selected based on 3 prior Delphi-based studies and 2 nationally validated scales. Round one created a collaborative list of items, round two validated items based on relevance, importance and feasibility and the final round classified items into one of four determinants: cultural, social, environmental or economic.

Results:

Panelists (69) from 13 countries participated in creating a final list of 62 items at 3 organizational levels. The sports club level included; 5 cultural, 6 social, 6 environmental and 5 economic items. The management level included; 5 cultural, 5 social, 5 environmental and 3 economic items. The coaching level included; 5 cultural, 5 social, 4 environmental and 4 economic items.

Conclusions:

This study provides three important innovations; 1- it is rooted in theory through the settings-based approach, 2- the measurement tool includes three levels within sports clubs, capturing a whole club dynamic and 3- all items included in the tool have been validated by an international panel of experts.

Key messages:

- This 62-item measurement tool allows the comparison of perceptions from participants, coaches and management regarding how health is promoted within their sports club.
- This information offers insight on the capacity of sports clubs to implement and monitor policies and practices on

- the promotion of health beyond sports performance within their organization.

Improving health outcomes in Northamptonshire's Homeless population

Samia Latif

S Latif[1], *A Sen*[2]
[1]East Midlands, Public Health England, Nottingham, UK
[2]Directorate of Public Health, Northamptonshire County Council, Northampton, UK
Contact: samia.latif@phe.gov.uk

Issue:

Homeless people experience inequalities and barriers to accessing healthcare. Northamptonshire had significantly higher number of homeless compared to the England average. This pilot aimed to provide health screening and interventions for Northampton's homeless population using an integrated system wide approach. This would inform commissioning and contribute to the database.

Description:

The project used a collaborative resource pooling approach by 24 NHS and non-NHS partners. Planning was reliant on information from voluntary sector so budgets were estimated. Health outreach clinics were planned over 3 months and delivered over 3 weeks at 10 voluntary centres offering blood borne viruses (BBV) and latent tuberculosis screening; basic health checks; and Hepatitis B and seasonal flu vaccinations. Unregistered people were supported to register with a GP. Evaluation will determine how to better collect data and promote and offer such a service.

Results:

127 people received basic health checks; 27 were overweight and 20 had high blood pressure. Of the 102 tested for BBVs, 5 were Hep C +ive and 2 were Hep B +ive. A fifth of those tested for LTBI were positive. In total, 67 Hepatitis B and 12 seasonal-flu vaccinations were given. 12 people required GP registrations. Primary and secondary care referrals were made. Following the pilot, services will provide wrap around care for Northamptonshire's homeless. Clinics at various times and locations will enable homeless people to engage with health and social services.

Lessons:

- Difficult to stratify the homeless and identify needs
- This innovative project was used as a case study by other areas
- Published data underestimates numbers of homeless
- Allow Adequate preparation for such events
- Consider health and safety risk assessment of venues during planning
- Staff continuity ensures consistent team working
- Dedicated communications lead support required

Key messages:

- Wraparound health promoting services are required to enable this cohort of population to engage with and seek health and social care.
- A multisectoral approach is required to improve and address inequalities of vulnerable groups.

The profile of people living in extreme poverty in the region of Crete

Maria Papadakaki

M Papadakaki[1], *MA Stamouli*[2], *S Diamanti*[1], *S Lioliou*[1], *P Maragkaki*[1], *M Pachiadaki*[1], *S Stavropoulou*[1], *K Kasotaki*[1], *G Tzamalouka*[1], *J Chliaoutakis*[1]
[1]LaHeRS Lab, Social Work Department, Hellenic Mediterranean University of Crete, Heraklion, Greece
[2]Department of Health Care Units and Business Administration, University of West Attica, Athens, Greece
Contact: mpapadakaki@yahoo.gr

Background:

The financial crisis of the last decade has increased the number of people living in extreme poverty in Greece. Until today, there is no research evidence on the bio-psycho-social needs of the population. The current study, among other, aimed at investigating the living and working conditions, the health and mental health status of these people and produced recommendations for health care policy and planning.

Methods:

A cross-sectional study was carried out in Crete Region with adult beneficiaries of material support benefits (according to income-related criteria). The study was part of the program FAED, which was co-funded by the EU and offered material support (e.g. food, material for personal hygiene, etc. to more than 17.000 beneficiaries in Crete region within 2016-2017. A structured questionnaire extracted information on various aspects including, working, housing and living conditions, health and mental health status.

Results:

798 individuals (46.5% male; 43.3 years) consented to participate and completed the questionnaire. Mean time of unemployment was 4.2 years. 26.8% was accommodated by relatives, 23.5% rented a house and 18% lacked heating. Nearly half of the participants reported a chronic disease (47.0%), 24.1% reported disability certified by health authorities. 4.9% had severe alcohol-related problems, 50.6% had mild to severe depression symptoms and 40.3% mild to severe symptoms of anxiety disorder. 12.0% totally lacked a support network for daily practical and emotional issues.

Conclusions:

Personal psychosocial needs seem to have been neglected because of complex family needs. Socioeconomic deprivation seems to have exacerbated chronic disease management due to neglect of health care needs. A huge burden of mental diseases is evident necessitating community mental health care.

Key messages:

- Mapping of bio-psychosocial needs is important for social policy and health care planning.
- Integrated care is necessary to meet the complex needs of people living in extreme poverty.

Romanian students' attitude and opinion about the smoke-free indoors law

Ileana Prejbeanu

IM Prejbeanu[1], *O Pita*[1], *ML Cara*[2]
[1]Environmental Health Department, University of Medicine and Pharmacy, Craiova, Romania
[2]Public Health Department, University of Medicine and Pharmacy, Craiova, Romania
Contact: ileana.prejbeanu@gmail.com

The Romanian Parliament approved the first piece of legislation regarding smoking in public places in 2002; smoking was banned in most indoors but allowed in bars and restaurants. The law has been amended several times; the 2016 amendment banned smoking in nearly all indoor public spaces, in indoor workplaces, in playgrounds and on public transport; there are only two exceptions to the law - cells in maximum security prisons and designated rooms in the transit areas of international airports.

In this context, we asked 498 students (in Law, Business Administration, Electronics, Languages, Sciences, Medicine, Dentistry, Pharmacy or Nursing), aged 21.93 ± 4.21 years, males and females, to answer a 23-item questionnaire on cigarettes smoking; the questionnaire included seven questions related to the Romanian smoke-free indoors law.

A number of 131 students (26.3%) are cigarettes-smokers; there are statistically significant differences among the faculties subgroups ($p < 0.01$), the highest percent of smokers being in Dentistry (50%) and the lowest - in Languages (13%). Most of the students (N = 466 - 93.6%) agree with the smoke-free indoors law; the disagreement is registered among the smokers (27 vs. 5 non-smokers, $p < 0.001$). A number of 360 subjects (72.29%) mention they met situations of smoking in public places: in bars/clubs/restaurants (73.3%), staircases of blocks of flats (56.1%), public transport or taxis (44.1%), even hospitals (8.3%) and classrooms (7.7%). In 75.8% out of these situations nobody took attitude; 40 students (11.1%) acted themselves and drew attention (most often successfully) to the smokers about breaking the law. One fifth of the smokers of the group have also smoked/intended to smoke in public places; most of them are students in Electronics and just one - in Law ($p < 0.05$).

Romanian students seem to be content with the ban of indoor smoking. Actions to reduce consumption of tobacco products and to protect public health have to be continued.

Key messages:

- Romanian young people seem to be content with the decrease of second hand smoke in indoor public spaces.
- Intense actions to combat the tobacco epidemic are still needed in Romania.

Sleep problems among Dutch higher educational students, working towards solutions

Claudia Van Der Heijde

C Van Der Heijde[1], *M Van Weeren*[1], *P Vonk*[1]

[1]Student Health Service, University of Amsterdam, Amsterdam, Netherlands

Contact: c.m.vanderheijde@uva.nl

Background:

Lately, attention for the role of sleep in health and wellbeing has increased. Short sleep duration and poor quality of sleep are associated with a higher chance at several (mental) health issues, including a higher mortality risk. Furthermore it is associated with attention problems and lower academic achievement. Poor sleep has a high prevalence, especially among students. We aim to provide (policy) recommendations from studying the associated factors on an individual and social level with poor sleep and its consequences.

Methods:

In a cross-sectional survey design (N = 493), the extent of sleep problems and its associated factors was studied amongst a group of Dutch students. The Pittsburg Sleep Quality Index (PSQI) was used. Linear regression analysis was performed. Participants were recruited through social media and e-mail (Male 43%; Female 57%; mean age, 22 years).

Additionally, experts were questioned in a small survey to come up with solutions (N = 24).

Results:

59% of higher educational students suffer from poor sleep quality. Factors that were significantly associated with worse sleep quality were: sleep need, behavior and psychology (effects stress overload), having a paid job in the evening/night, loneliness, having the Chinese and other ethnicity and having a sleep-related disorder. Sleep was significantly associated with worse mental health, vitality and drug use. Additionally, sleep was a significant predictor for attention problems and worse academic performance in the current academic year.

Conclusions:

Nearly 2 out of 3 students suffered from poor sleep quality, reconfirming the high prevalence amongst higher educational students in other studies. Universities can contribute to better sleep quality of their students by educating their students more about sleep hygiene (including effects of drugs and how to deal with high work pressures), and make them more aware of the availability of student psychologists and student general practitioners.

Key messages:

- Students in higher education are a population at high risk for poor sleep quality.
- More attention for the importance of sleep for health, wellbeing and academic achievements should be implemented in the university institutional context.

Using retrospective process analysis to identify lessons learned from a community health initiative

Kristina Hoffmann

C Schluefter[1], *M Albrecht*[1], *J E Fischer*[1], *S Georg*[1], *K Hoffmann*[1]

[1]Mannheim Institute of Public Health, Univeristy of Heidelberg, Mannheim, Germany

Contact: Kristina.Hoffmann@medma.uni-heidelberg.de

As the WHO-Health-in-all-Policies-concept suggests many of the health-related aspects of the social, physical and economic environments can be modified within the community setting. In reality, developing and implementing population-based health initiatives is often challenging for both communities and researchers. To guide future efforts of community health initiatives, we systematically analyzed challenges we encountered and the lessons learned.

We systematically reviewed daily logbooks, meeting minutes and press releases about the initiative to identify successes, unexpected challenges and barriers in its implementation. Comments from two reflective workshops held in the partner community identified additional areas of knowledge. Retrospective content analysis of these sources uncovered emerging process-related themes.

Success was evident in a high degree of citizen participation in initiative-related forums. Challenges included a greater need to a) develop a common vision before starting initiative activities, b) establish an effective collaboration between community residents and our team, c) create more transparent lines of communication, foster trust and better manage community expectations. Establishing a project office in the community for regular updates, trust building and partnering with a professional communication agency were key steps that helped turn some challenges into successes. Barriers identified were missing resources both within the community and our team, a limited time period and limited possibilities of reach into all systems within the community (e.g. kindergartens).

The use of the method of retrospective process analysis helped to uncover detailed insights into the operational implementation process of a community health initiative. These insights serve as a transfer of practical knowledge, which intends to enable researchers and practioneers within communities to plan and conduct their community health initiatives to large success.

Key messages:

- Analyzing the process of health initiatives retrospectively uncovers detailed insights into implementation processes and helps to understand successes, challenges and barriers of the initiative.
- Insights into the implementation process of health initiatives function as guidance to other researchers and practioneers to support future efforts in the field of community health.

Perceived needs of elderly for living a self-reliant life: implications for municipal health policy

John Dierx

J Dierx[1]

[1]Research Group Living in Motion, Avans Hogeschool, Breda, Netherlands

Contact: jaj.dierx@avans.nl

Background:

The population in the Netherlands and in the municipality of Oss is getting older in good health and wellbeing, living more independently and self-reliant with changing needs of support (Hilderink, 2018). However, offered support by health care and wellbeing professionals has not changed. Since it is unknown whether offered support matches the changed needs, the municipality of Oss wanted to know what elderly perceive supporting them in self-reliant life so they could be empowered by more effective supported and more efficient use of staff and finances. Results might have implications for more municipalities with an aging population.

Methods:

41 Elderly (age 65-92 y) in Oss were invited to enjoy a meal prepared by their grandchildren at their school and attend a Structured Interview Matrix-session (O'Sullivan et al., 2013) at the same time to map their perceived needs for an self-reliant life. Collected voice recorded data were transcribed and analyzed using thematic analysis (Braun & Clarke, 2006).

Results:

Results show that elderly prefer living independently, self-reliant and being self-supporting as long as possible first in physical mobility (walking, biking, driving a car), second in socially with respectively their children, friends and neighbors and third in financially independency. When inevitably getting dependent, they prefer help from children, friends and neighbors for practical daily living activities (e.g. cleaning, gardening, groceries). However, concerning medical care they prefer health and wellbeing professionals with general practitioner and municipality as gateway.

Conclusions:

Elderly want to be self-reliant as long as possible, living in their own house and neighborhood. When getting dependent, they prefer friends and neighbors for assistance in daily living and support from health and wellbeing professionals only for medical assistance with a key role for the municipality and general practitioner.

Key messages:

- Elderly prefer living a self-reliant life as long as possible in their own house and neighborhood.
- Municipal health services are perceived to play a key role in supplying adequate support from Health and wellbeing professionals.

Improving Health Literacy in Austrian Companies: Results from a Systematic Company Recruitment

Madlene Movia

K Hofer-Fischanger[1], M Movia[1], S Tuttner[1], B Fuchs-Neuhold[1], A Müller[1], F Amort[1], G Grasser[1]
[1]Health and Tourism Management, FH JOANNEUM – University of Applied Sciences, Bad Gleichenberg, Austria
Contact: madlene.movia@fh-joanneum.at

Issue:

The HL-Survey-EU-2011 showed limited health literacy (HL) among the Austrian population (51,6%), especially in the federal state of Styria (63,1%). The project ‘‘Auf Gesundheitskurs - gesundheitskompetent in Feldbach’’ focuses on individual and organizational HL by training and educating production and service company workforce in a rural region in Austria.

Description:

The population in the target region is especially disadvantaged regarding HL due to the parameters of age, gender, education, income and ethnicity. There are several small and medium-sized businesses within this area. This project (2018-2020) aims to improve knowledge, competences and skills of multipliers from different companies concerning organizational and individual HL, based on an in-person training programme. However, in order to recruit participants for this research project, a systematic recruitment approach was used.

Results:

A total of 783 companies, listed in the community database, were contacted via email in order to inform about the project and to invite for an interview. After the initial email, 40 companies were selected, based on four characteristics: industry sector, company size, distance to town centre, relevance to HL, and contacted via phone as well. However, 7 companies out of 783 confirmed the first interview and 6 out of 7 signed the project cooperation. 18 out of 40 phone contacts led to personal meetings, 9 resulted in signing the cooperation. In total, 15 companies have decided to participate in the project.

Lessons:

Overall, telephone contact led to much higher response rates than email alone. The parameters which effected positive outcomes during the interaction by phone and in-person were demonstrating benefits (healthy workplace, motivated staff, positive atmosphere, new customers), explaining the practical value, clarifying costs, expenditures and time effort. Although the topic of workplace health promotion is popular in this rural region, the focus on HL is new.

Key messages:

- Key factors in company recruitment for HL initiatives in rural regions are telephone and personal contact.
- Pointing out specific benefits for companies within the recruiting process seems also crucial.

School children’s perspectives on food literacy as competencies – insights from a qualitative study

Cecilie Karen Ljungmann

C Ljungmann[1], N Stjernqvist[1], A Bonde[1]
[1]Health Promotion, Steno Diabetes Center Copenhagen, Gentofte, Denmark
Contact: cecilie.karen.ljungmann@regionh.dk

Background:

Food literacy (FL) has developed as a relatively new theoretical concept, which according to Benn (2014) captures not only knowledge about healthy food (to know) and cooking skills (to do), but also the sensing of food (to sense), care of others (to care) as well as citizenship involvement in food issues (to want). Empirical studies of the concept are, however, few. The aim was to test the applicability of the 5 theoretical competencies of food literacy in school children aged 12-14 years.

Methods:

The operationalisation of the theory into a practical context occurred in three steps using a qualitative approach; 1) Concretizing the domains of the model by defining sub elements to each domain and questions to each sub element. 2) Reviewing questions by a panel of 10 experts in food and education, and subsequently adjusting and reducing according to comments. 3) Conducting participatory observations on a food camp and 4 focus group interviews with a total of 21 school children.

Findings:

In practice the competencies are often complementing each other as described by the theory. In relation to the competence ’to know’, the children argued how they achieved more knowledge through hands-on activities. An important element of the competence ’to do’ was getting support from adults when trying new techniques. ’To sense’ was illuminated in the children’s talks about learning to seasoning. ’To care’ was apparent in the children’s appreciation of making food together and the development of cooperation skills while ’to want’ was observed in making of leftovers into ‘‘new’’ dishes and talks on subjects such as food production.

Conclusions:

The 5 competencies can be found in everyday practices and are often complementing each other in a learning process. This highlights the need to build on a broad concept of food literacy that addresses more than one competence hence creating broader understandings and practical skills.

Key messages:

- This study has tested the applicability of a theoretical concept, food literacy, and has found it useful in practice to highlight specific competencies and their interconnectedness.
- The insights into practical examples of the interconnected competencies can be used to guide future interventions that aims to promote food literacy.

A Bridge to Wellness: Gains from a health fair among fishermen in the Port of New Bedford, USA

Maryellen Brisbois

M Brisbois[1], H Silva[2], A Santos[2], H Canasta[1], A Feno[1], L Cabral[2], R Soares[2]
[1]Community Nursing, University of Mass Dartmouth, Dartmouth, USA
[2]School of Health, University of the Azores, Ponta Delgada, Portugal
Contact: mbrisbois@umassd.edu

Background:

Globally, it has been noted that fishermen have a higher mortality from cardiovascular disease, cancer, and injury from work-related accidents when compared to the general population. A potential increase in unemployment in fishermen in

New Bedford could result in a lower income level which relates to an increase in risk behaviors, less health screenings, and negative health behaviors. While there is a lack of health-related data among fishermen across the globe, there is little information regarding the health among fishermen, who are predominantly immigrants, in the US.

Objectives:

The objectives include designing a health promotion fair to prepare nursing students with the skills to educate fishermen associated with nutrition, diabetes mellitus, cancer and hypertension as identified by key informants in the community.

Results:

Students expressed gains in achieving nursing competencies related to collaboration, communication, and teaching/learning by designing a fair with stations related to the four health topics with posters and activities. Educational materials were available in both Portuguese and English to support this aggregate who expressed learning new knowledge. Networking among local fishing agencies, nursing students and the fishermen supported this project from start to finish.

Conclusions:

Despite limited access to this vulnerable group, learning nursing competencies and increased fishermen's knowledge were realized. Connecting students with vulnerable populations is an effective way to promote learning for both groups.

Key messages:

- Multiple gains are noted when nursing students are paired with vulnerable community aggregates.
- Learning to work in the community with local agencies and groups is an effective teaching/learning pedagogy.

Internalization of rules and risk-behavior among early adolescents and relevance for public health

Jozef Benka

J Benka[1], O Orosova[1], M Bacikova-Sleskova[1]

[1]Department of Educational Psychology and Health Psychology, Pavol Jozef Safarik University, Kosice, Slovakia

Contact: jozef.benka@upjs.sk

Introduction:

Self-determination theory (SDT) is a macro theory of human behavior and provides a substantial theoretical background for understanding and changing qualitative aspects of behavioral regulation such as the level of internalization in the context of health-related behaviors of individuals and communities. The aim of this study is to use this theory to focus on the internalization of parental rules in early adolescents in Slovakia and examine it in relation to their risk behavior.

Methods:

A sample of 581 early adolescents (mean age = 12.5 SD = 0.5; 49% girls) from Slovakia participated in a larger project focusing on health-related behaviors (APVV-0253-11, APVV-15-0662). They completed measures based on SDT addressing the level of internalization or parental rules and the risk behaviors of alcohol use and smoking. These risk behaviors were measured on a dichotomous level (used/ not used). Binary logistic regressions were used to explore the relationship between the level of the internalization of rules with respect to alcohol use and smoking controlling for the relevant variables.

Results:

The results of the analyses showed that after controlling for age and gender, internalized parental rules were negatively associated with alcohol use (95%CI = 0.918-0.981). Conversely, the extrinsic regulation of parental rules indicated a higher likelihood of using alcohol (95%CI = 1.039-1.151). However, this was not observed in smoking which was found to not be associated with rule internalization.

Conclusions:

The findings stress the importance and relevance of the internalization process when studying behavioral regulation in the context of health. This was demonstrated in the internalizing of parental rules among early adolescents. However, the findings also suggest that a different approach might be needed with different contexts and different health related behaviors.

Key messages:

- Acknowledging the importance of the qualitative aspects of self/behavioral regulation such as the level of internalization may improve public health interventions.
- A different approach might be needed when internalization is considered in different contexts and different health related behaviors.

Eating disorders among university students: a public health challenge. An European study

Joel Ladner

J Ladner[1], A Lukács[2], I Brumboiu[3], E Ciobanu[4], C Croitoru[4], P Sasvári[5,2], MP Tavolacci[1]

[1]INSERM 1073, University of Rouen, Rouen, France

[2]Faculty of Health Care, University of Miskolc, Miskolc, Hungary

[3]Epidemiology and Primary Health Care Department, Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania

[4]Nicolae Testemiţanu State University of Medicine and Pharmac, Nicolae Testemiţanu State University of Medicine and Pharmacy, Chisinau, Moldova

[5]National University of Public Service, Budapest, Budapest, Hungary

Contact: joel.ladner@univ-rouen.fr

Background:

Eating disorders (ED) and behavioural risk factors among students in higher education remain to be investigated. The aim of the study was to identify the prevalence of ED and the behavioural factors associated with ED in university students in four European universities: Chisinau (Ch) in Republic of Moldava, Cluj-Napoca (CN) in Romania, Miskolc (Ms) in Hungary and Rouen (R) in France.

Methods:

In the four countries, students in higher education completed an anonymous standardized self-questionnaire, from 2016 to 2018. The questionnaire collected age, gender (M, W), housing, curricula, smoking, cannabis consumption, alcohol abuse problems (ADOSPA test), and perceived stress (Cohen score). The Sick, Control, One stone, Fat, Food (SCOFF scale) screening test was used to identify student with ED.

Results:

A total of 3076 students were included, 705 in Ch, 582 in CL, 534 in Ms and 1255 in R. The sex-ratio was M:F = 0.31 Ch, 0.30 in CN, 0.44 in Ms and 0.66 in R. The mean age was 21.2 (SD = 3.98) in Ch, 21.2 (SD = 3.2) in CL, 23.8 (SD = 5.1) in Ms and 20.0 (SD = 3.4) in R. The global prevalence of ED was 23.8%. According to the gender, the prevalence of ED in the four universities was 14.7% in M and 38.3% in W in Ch, 21.8% in M and 24.7% in W in CN, 19.7% in M and 21.4% in W in Ms and 16.1% in M and 34.0% in W in R ($p < 10\text{-}4$). After logistic regression, significant positive relation between the positive SCOFF was observed with female gender, alcohol abuse problems and stress level.

Conclusions:

ED prevalence patterns were quite similar in the four countries, with high prevalence of ED, even in men. Associated behavioural risk-factors were quite similar. It might be necessary in the future to screen students for potential ED upon entry to the university and also to inform student about the risk of ED and advise them to consult a healthcare professional.

Key messages:

- Our study highlights the high prevalence of eating disorders, with similar behaviours in university students in four countries.
- Because of the detrimental effects of ED on physical and emotional health, it seems mandatory to set up public health programs (health promotion, prevention).

Learning from calorie posting/traffic light systems introduction in a University hospital canteen

Patricia Fitzpatrick

P Fitzpatrick[1,2], C Flood[1], E Cuniffe[1], K Doherty[1], A Lyons[1], S Stynes[1], A Pilkington[3], L Barnes[3], T Peare[4], CC Kelleher[1,5]
[1]Department of Preventive Medicine & Health Promotion, St Vincent's University Hospital, Dublin, Ireland
[2]School of Public Health, Physiotherapy & Sports Science, University College Dublin, Dublin, Ireland
[3]Department of Dietetics, St Vincent's University Hospital, Dublin, Ireland
[4]Department of Catering, St Vincent's University Hospital, Dublin, Ireland
[5]College of Health & Agricultural Sciences, University College Dublin, Dublin, Ireland
Contact: patricia.fitzpatrick@ucd.ie

Calorie posting is now policy in hospitals in Ireland and restaurants will be required to display calorie counts on menus by end of 2019. The Health Promotion, Dietetics and Catering teams worked together to introduce calorie posting and a traffic light system (TLS) for all foodstuffs available in the staff canteen of a large University teaching hospital in Dublin, Ireland. A calorie posting launch took place in September 2018. The aim of this study was to determine staff perception of calorie posting and TLS.

One month after the launch, 343 staff members were surveyed using a short pre-designed Sphynx-software questionnaire at 3 time points daily over one week, at breakfast, lunch and evening mealtimes. SPSS was used for analysis.

Of the 353 respondents (65.3% female; 18-44 years 65.3%, 45+ 32.1%, unknown 2.6%), more staff found calorie posting helpful compared to TLS (66.5% vs 43.7%; p = 0.001). Staff stated they made themselves aware of calorie count always/mostly (46%) and sometimes (26.2%). More females than men found both calorie posting (72.3% vs 53.3%; p = 0.001) and TLS (49.1% vs 31.8%; p = 0.001) helpful. More respondents identified calorie posting than TLS as influencing food choice at least sometimes (60.3% vs 36%; p = 0.0001). Females were more likely to make a food choice change based on TLS (39.7 vs 20.6%; p = 0.01). Age and frequency of canteen use were not associated with either.

The results suggest calorie posting is used rather than TLS by all hospital staff and female hospital staff are likelier to use both. Learning from this study, the positioning of TLS in relation to individual foodstuffs has been reviewed, further promotion of TLS/calorie posting has taken place in the hospital and a regular audit has been established. Notwithstanding the challenges, important moves towards healthier choices were seen.

Key messages:

- Introduction of traffic light system and calorie posting needs evaluation.
- Females appear more likely to avail of traffic light systems and calorie posting in relation to food choices.

Health literacy and physical activity as buffers to counter act work related stress

Luís Saboga-Nunes

L Saboga-Nunes[1,3,4], R Guerra[2], P Madaleno[2], T Santos[2]
[1]ProLiSa; Centro de Investigação em Saúde Pública, Universidade NOVA de Lisboa, Lisbon, Portugal
[2]Escola Nacional de Saúde Pública, Universidade NOVA de Lisboa, Lisbon, Portugal
[3]Institute of Sociology, University of Education, Freiburg, Germany
[4]Instituto de Saúde Ambiental, Faculdade de Medicina, Universidade de Lisboa, Lisbon, Portugal
Contact: saboga.nunes@gmail.com

Background:

Stress health problems affect 47.8% of the work force in Portugal. It is predicted that, in the next decade, these problems will overcome musculoskeletal disorders, the first cause of employee's withdrawal from work. Research indicates connections between stress and dimensions of the work place (like job satisfaction). Nevertheless the conceptual understanding of these relationships is sparse. In order to better understand these relationships, this research focus on the use of job–specific models of stress, associating them with health literacy (HL) - in the context of the European Health Literacy Survey framework (HLS-EU) - and physical exercise.

Methods:

A total of 748 participants from the different offices of a company in the financial sector (Portugal, main land and autonomous territories) participated in a cross sectional survey (CAWI). Age ranged from 25 to 65 years and HL was measured using the HLS-EU instrument validated to Portuguese (HLS-EU-PT). Each participant was allocated to one of the groups, either of satisfactory HL (when scores ≥ 30) or insufficient HL (when scores <30).

Results:

Out of the 748 participants (58.7% males, average age of 39 years), 80.4% sometimes and very often experience stress and tension in the workplace. Less than one in every two (44.4%) practice physical activity several times a week. Of the participants, 7.1% have inadequate, 39.0% problematic, 36.6% sufficient and 17.3% excellent HL (HLS-EU-PT). Employees that are more active are those who experience lower levels of stress.

Conclusions:

The research of the effects of HL combined with physical exercise, as buffer variables to problems related to the effects of work stress, is a new area of research that may help understand patterns of adherence to activities that can help workers deal with everyday working conditions. More research is needed to integrate HL strategies in the work place.

Key messages:

- Stress health problems affect 47.8% of the work force in Portugal.
- Employees that are more active are those who experience lower levels of stress.

Importance of Health literacy in magnesium supplementation - Case study Novi Sad, Serbia

Marija Jevtic

J Gajic[1], D Dimovski[1], B Vukajlovic[1], M Jevtic[1,2]
[1]Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia
[2]Institute of Public Health of Vojvodina, Novi Sad, Serbia
Contact: marija.jevtic@uns.ac.rs

Background:

Currently the market offers wide range of magnesium dietary supplements that vary either in their pharmaceutical dosage form (capsules, tablets, direct form, effervescences etc.), magnesium compound present (magnesium oxide, - chloride, -citrate,- bisglycinate, -acetyltaurinate etc.) their dosage (ranging from 150 to 400mg) or other vitamins and minerals present (vitamin B complex, vitamin C, zinc, manganese etc). Since the public can now choose to buy dietary supplements not only from pharmacies and specialized stores but from places such as supermarkets, cosmetic shops or even markets it is important to educate the public and help them make healthier choices.

Objectives:

While providing primary health care services in public pharmacy, overall choices and reasons for buying magnesium supplements were noted during the first four months of 2019 (January to April). The goal was to investigate the most important factors patients consider when opting to take magnesium supplements as well as their health literacy regarding the topic.

Results:

The results indicate that the currently most popular choices are mouth dissolving forms of magnesium (more than 50% units sold), and predominantly forms the magnesium oxide form (around 75%). It is suggested that the most important factors when choosing magnesium dietary supplements are its price, media presence, friends advice, general familiarity or even product design as very few the patients asked about the present form of the magnesium.

Conclusions:

Magnesium dietary supplements belong to highly desirable supplements on the free market. It is observed that patients choice mostly doesn't coincide with health authorities recommendations.

Key messages:

- Importance of health literacy and understanding the dietary supplement labels.
- Higher impact of sources of information other than healthcare authorities.

DP Infectious diseases, preparedness and vaccines

Age, period, and cohort effects on infectious disease mortality in Korea, 1983-2017

Sang Jun Eun

H-S Kim[1], *SJ Eun*[2]
[1]Korea Centers for Disease Control and Prevention, Cheongju, South Korea
[2]Department of Preventive Medicine, Chungnam National University College of Medicine, Daejeon, South Korea
Contact: zepplin7@cnu.ac.kr

Background:

Infectious diseases are a leading cause of death worldwide, and constitute a significant burden of disease, even in developed countries including Korea. Although different ages, periods, and cohorts may affect mortality, few studies analyzed the epidemiologic pattern of infectious disease mortality considering these effects. This study aimed to estimate the age-period-cohort effects on infectious disease mortality in Korea.

Methods:

The national death certificate and census mid-year population estimates data from 1983 to 2017 were categorized into 5-year age groups and 5-year periods. Infant deaths were excluded due to incomplete data. Intrinsic estimator regression models were fitted to estimate age-period-cohort effects on infectious disease mortality.

Results:

A J-shaped age effect declined from age 1-4 years (intrinsic estimator coefficient [IEC] 0.68; 95% confidence interval [CI] 0.52, 0.85), the lowest at age 20-24 years (IEC -1.68; 95% CI -1.85, -1.51), and then increased with age. The declining trend of period effects was slowed down in 1998-2002 (after the 1997-1998 Asian economic crisis), and turned to an upward trend from 2008-2012 (after the 2008-2009 global financial crisis). The cohort effect increased from the earliest cohort born before 1905 (IEC -1.17, 95% CI -1.35, -0.98), peaked in the 1941-1945 cohort (IEC 1.20, 95% CI 1.10, 1.29), then plateaued out (IEC ranged from 0.93 to 1.10), and has continued to decline since the 1966-1970 cohort in which rapid economic growth began.

Conclusions:

There were clear age, period, and cohort effects on infectious disease mortality in Korea. Through the period and cohort effects, the economic downturn and upturn might have increased or reduced infectious disease mortality, respectively. Recent upward trend in infectious disease mortality after the 2008-2009 financial crisis suggests a need to strengthen prevention and control of infectious diseases.

Key messages:

- It is important to consider age-period-cohort effects in identifying the epidemiologic pattern of infectious disease mortality trend and finding its underlying drivers.
- Economic cycle might have influenced infectious disease mortality through period and cohort effects.

Survey of nosocomial influenza in South-western Swiss hospitals during two seasonal epidemics

Delphine Hequet

D Hequet[1], *L Qalla-Widmer*[1], *C Balmelli*[2], *O Clerc*[3], *U Fuehrer*[4], *A Iten*[5], *V Portillo*[6], *L Senn*[7], *N Troillet*[8]

Contact: delphine.hequet@chuv.ch

Nosocomial influenza increases morbidity and mortality in hospitalised patients. No multicentre study analysed its impact in Swiss hospitals yet. This study was conducted From November 1st to April 30th in 2016-2017 and 2017-2018 in 27 acute-care public hospitals in South-western Switzerland. It aimed at describing nosocomial cases of seasonal influenza. During these 2 time-periods, every patient hospitalized for >72 hours that was positively screened by RT-PCR or antigen detection for influenza was retrospectively included in the survey. Policies to prevent influenza were collected in each participating hospital. Characteristics of patients included age, sex, and comorbidities. Included patients were followed-up until discharge or death. Complications and administration of anti-neuraminidases and/or antibiotics were registered.

The mean influenza vaccine coverage of healthcare workers (HCW) was 40%. 836 patients were included (98% with a type A influenza virus in 2016-2017; 77% with a type B virus in 2017-2018). Most patients (81%) had an unknown vaccine status. Overall, the incidence of nosocomial influenza was 0.3/100 admissions (0.35/1000 patient-days). The most frequent comorbidities were diabetes (21%), chronic respiratory diseases (18%), and malnutrition (17%). Fever (77%) and cough (66%) were the most frequent symptoms. 70% of patients received anti-neuraminidases, 28% received antibiotics. Infectious complications such as pneumonia were reported in 8%. Overall, the all-cause mortality was 6%.

The occurrence of nosocomial influenza underlines the importance of vaccinating patients and HCW, rapidly recognising community or hospital-acquired cases, and applying adequate additional measures to prevent dissemination, including the timely administration of anti-neuraminidases to avoid antibiotic use (and misuse).

Key messages:

- Important to encourage patients to be vaccinated against influenza.
- Apply additional measures in order to prevent influenza dissemination.

Seroprevalence of anti-Parvovirus B19 IgG in childbearing age women in Pleven region (Bulgaria)

Silviya Yankulovska

T Petkova[1], *S Pachkova*[2], *Tz Doichinova*[3], *S Aleksandrova-Yankulovska*[4]
[1]Department of Infectious Diseases and Epidemiology, Medical University, Pleven, Bulgaria
[2]Medical Center, Clinical Institute for Reproductive Medicine, Pleven, Bulgaria
[3]Department of Infectious Diseases and Epidemiology, Medical University, Pleven, Bulgaria
[4]Department of Public Health Sciences, Medical University, Pleven, Bulgaria
Contact: silviya_aleksandrova@hotmail.com

Background:

Parvovirus B19 is a widespread infection in childhood. Seroprevalence of anti-Parvovirus B19 increases with age and about 60% to 70% of women of childbearing age have serological evidence of past exposure to virus. Diaplacental

Parvovirus B19 infection in pregnant women can lead to anaemia, non-immune hydrops fetalis and foetal death. The aim of the study is determining the susceptibility to Parvovirus B19 in childbearing age women.

Methods:

We conducted a prospective seroepidemiological study in which 90 healthy women of childbearing age (19 to 40 years) were tested during the period September-October 2018 in Medical Center "Clinical Institute for Reproductive Medicine"- Pleven, Bulgaria. Participants were surveyed on a voluntary basis. The exclusion criteria were: presence of autoimmune disorder, immunosuppressive states, malignancy and populations at risk such as persons under 18 years of age and pregnant women. The presence of specific Parvovirus B19 IgG was detected using a standardized anti-Parvovirus B19 (IgG) ELISA kit. The demographic and anamnestic data were collected for each participant in Case Report Form.

Results:

The average age of the women was 31.4 ± 4.9 years. Dominating were women with higher education (52.2%) living in urban areas (92.2%). The survey results showed that 37.8% of women were positive for anti-Parvovirus B19 IgG, 61.1% were negative and 1.1% equivocal. Immunty to the virus increased from 27.3% to 45% with age. There was no significant correlation between the presence of antibodies and the demographic factors (living area, education and number of family members).

Conclusions:

The results of this study imply that 61.1% of the childbearing age women in Pleven region are susceptible to infection with Parvovirus B19. Because of the high susceptibility to Parvovirus B19, active monitoring of risk groups pregnant women for the prevention of fetal complications is recommended.

Key messages:

- There is no specific treatment or prophylaxis against Parvovirus B19 infection and epidemiological surveillance requires the introduction of effective preventive measures at the public health level.
- Active monitoring in childbearing age women is necessary to reduce the risk of fetal damage and the cost of healthcare associated with the infection.

Effect of rotavirus vaccination offer to children observed in Italy between 2010-2018

Francesca Antinolfi

F Antinolfi[1]*, L Brunelli*[2]*, T Gallo*[3]*, F Valent*[4]
[1]Hygiene and Public Health School, Department of Medicine, University of Udine, Udine, Italy
[2]Department of Medicine, University of Udine, Udine, Italy
[3]Public Health Department, Udine Healthcare and University Integrated Trust, Udine, Italy
[4]Institute of Hygiene and Clinical Epidemiology, Udine Healthcare and University Integrated Trust, Udine, Italy
Contact: antinolfi.francesca@spes.uniud.it

Background:

Rotavirus (RV) is the most common cause of gastroenteritis (GE) among children under 5 years. Since 2012 Friuli Venezia Giulia (FVG) Region (Italy) has offered free RV vaccination to low birthweight preterm and other at-risk babies. Starting from 2018, the offer has been extended to all newborns. Aim of the study is to investigate the effectiveness of RV vaccination offer on coverage and GE-related hospital admissions among FVG children under 1 year between 2010-2018.

Methods:

With a retrospective analysis we identified FVG Region children <1y with at least one dose of RV vaccine and children <1y admitted to hospital with a diagnosis of Non-Specific GE (NSGE; ICD9-CM codes 001-009) and RVGE (008.61) from 2010 to 2018. Vaccination coverage and hospitalization risk in each annual child cohort were calculated. Hospitalization and vaccination data were also linked using a univocal anonymous stochastic key.

Results:

Of 77,330 children (51% males) born in FVG during 2010-2018, 8209 (11%) were vaccinated for RV. Coverage progressively increased from 0.2% in 2010 (22/9736) to 23% in 2017 (1782/7747) and then almost tripled in 2018 reaching 67% (5006/7425). During the 9 years observed, 414 children were hospitalized for NSGE (0.5%) and 172 for RVGE (0.2%). NSGE hospitalizations started from 48 (0.5%) in 2010 and reached 58 (0.8%) in 2018. Admissions for RVGE were 27 (0.3%) in 2010 and decreased to 15 (0.2%) in 2018. Annual hospitalization rate fluctuated with no clear pattern. In the observation period, 11 RV vaccinated children were admitted to hospital for NSGE (2.6% of total NSGE admissions), 1 of them specifically with RVGE.

Conclusions:

The offer of RV vaccination to newborns results to be effective to gain vaccine coverage among children under 5 years. The impact of this offer on GE-related hospital admission and RVGE in particular cannot be properly evaluated yet, as not enough time has passed since the implementation of free offer to all newborns.

Key messages:

- Defining and implementing an appropriate vaccination offer is essential to ensure adequate levels of coverage against Rotavirus among children under 5 years.
- The evaluation of the effect of Rotavirus vaccination on hospital admissions for NSGE and RVGE needs a careful and continuous assessment in next years.

Evolution of Healthcare-associated infections over five years: results of prevalence surveys

Hela Ghali

H Ghali[1]*, A Ben Cheikh*[1]*, S Bhiri*[1]*, S Khefacha Aissa*[1]*, L Dhidah*[1]*, M Ben Rejeb*[1]*, H Said Latiri*[1]
[1]Department of Prevention and Security of Care, Sahloul University Hospital, Faculty of Medecine of Sousse, University of Sousse, Sousse, Tunisia
Contact: yasminebenrejeb@hotmail.com

Background:

Tunisia is not spared from the scourge of healthcare associated infections (HAIs). National surveys on the prevalence of HAIs on a given day have regularly taken place in health facilities. We aimed to describe bacteriological profile as well as treatment modalities of HAIs in Sahloul Hospital for the last five years.

Methods:

We conduct every year a prevalence survey, as part of the program for the prevention and control of HAI at Sahloul Hospital. It is a cross-sectional study of one-day prevalence with a single pathway. All departments were included in the survey, except emergency and hemodialysis services due to their very short length of stay. Data collection was carried out using NosoTun plug (national HAI prevalence survey).

Results:

Over five years, prevalence of HAI ranged from 11.4% in 2014 to 7.1% in 2018. In 2014, bacteriological analysis was performed in 55.8% of HAI cases. In 66.6% of cases (n = 16), isolated bacteria were gram negative bacilli, the most frequent were Pseudomonas aeroginosa. In 2015, 17 germs were identified, and in 88.2% of cases (n = 5), isolated pathogens were also gram-negative bacilli, the most frequent were Pseudomonas aeroginosa (n = 4) and Acinetoobacter baumanii (n = 3). Besides, cephalosporin 3rd generation was the most frequent antibiotic used for the treatment. However, in 2016, Klebsiella Pneumoniae was the most frequent germ isolated. Among those infected patients, 26 were treated (92.8%). In 2017, 26 germs were identified, the most frequent were Gram Negative Bacilli (53.8%), mostly Escherichia coli and Pseudomonas aerginosa, followed by Acinetobacter baumanii. in 2018, 16 germs were identified, the most frequent were Gram Negative Bacilli (55.5%), mostly Klebsiella Pneumoniae.

Conclusions:

The challenges for the future are to minimize infection with gram-negative bacilli while limiting the emergence of antibiotic resistant organisms.

Key messages:

- Our study helped us to have an insight into the most common isolates identified throughout the last five years.
- An incidence survey was carried out to better highlight the impact of healthcare associated infections in our hospital.

A systematic review of prediction models used in tuberculosis contact tracing

Farah Kidy

F Kidy[1], E Bruno-McClung[1], S Shantikumar[1], W Proto[1], O Oyebode[1]
[1]Warwick Medical School, University of Warwick, Coventry, UK
Contact: f.kidy@warwick.ac.uk

Background:

Contact tracing forms a key part of tuberculosis (TB) control in high-income, low-incidence settings. It aims to reduce morbidity, mortality and onward transmission of TB. Contact tracing is a complex and resource intensive intervention. Risk assessment of contacts is needed to ensure appropriate allocation of resources and greatest possible impact. Current prioritisation procedures are based on expert opinion and consensus. Prognostic prediction models offer a way to synthesise evidence about this decision.

Methods:

We searched Medline, Embase, BNI, CINAHL, HMIC, and the Cochrane Library for peer reviewed publications in English about TB contact tracing prediction models. Studies were included if there was statistical combination of predictors. No date, age or other restrictions were applied. Study selection was carried out by two independent reviewers. Data were extracted using the CHARMS checklist and studies evaluated for risk of bias using PROBAST.

Results:

Five reports were selected from a total of 16,585 non-identical returns. Each study was carried out in demographically distinct settings (Peru, USA, France, Taiwan). The choice and definition of outcomes and predictors varied. All the models included external validation and some included internal validation. Calibration and discrimination measures were variably reported. The models were at high risk of bias due to challenges in defining TB disease and due to statistical approaches taken: there was poor reporting of sample size considerations, universal use of univariable analysis to select predictors, and dichotomisation of data. There were some concerns about applicability due to differing populations and diagnostic approaches. None of the models included social risk factors.

Conclusions:

The use of existing models is problematic. There are constraints upon resources which means that contact tracing needs to be carried out efficiently. A robust prediction model is urgently needed to achieve this.

Key messages:

- Contact tracing for tuberculosis would benefit from more robust prioritisation tools to save resources and increase impact.
- Existing prognostic prediction models are at high risk of bias and there are concerns about applicability in high-income, low-incidence settings.

Measles situation in Ukraine during the period 2017-2019

Roman Rodyna

R Rodyna[1]
[1]Epidemiological Surveillance Department, Public Health Center, Kyiv, Ukraine
Contact: rodmanmail2@gmail.com

Background:

Measles remains a significant cause of death among children globally, despite the availability of effective vaccine. While global measles deaths have decreased by 84% worldwide from 2000 to 2016, measles is still common in many countries, particularly in Africa and Asia: during 2016 7 million people were affected. In Ukraine 12,000 people suffered from measles in 2012. The last outbreak in Ukraine started in 2017, continued in 2018 and it is ongoing in 2019. Totally about 100,000 people fell ill, 31 died and it is one of the biggest outbreaks in Europe in the last 20 years. Our work was aimed to analyze the measles outbreak in Ukraine and find out its causes in 2017-2019.

Methods:

We conducted an analysis of measles incidences in Ukraine during the period 2017 - 2019 using analytical and epidemiological methods.

Results:

The number of reported measles cases was: in 2017 - 4782 in 2018 - 53,219, 3 month of 2019 - 34,188. In 2016 the number of measles cases was 102. The incidence rates of measles per 100,000 population were: in 2016 - 0,24; in 2017 - 11,2; in 2018 - 125,2; in 2019 (3 month) - 80,4. Comparatively to the 2016 incidence rates increased 46 times in 2017 and 521 times in 2018. The percentage of children among suffered people was: in 2017 - 66,6%; in 2018 - 55,3%; in 2019 - 47,8%. According to the national vaccination schedule, 1 dose of MMR (MMR1) vaccine children get in 12-month age, the second dose (MMR2) - in 6-years age. Vaccination coverage of MMR1 and MMR2 vaccines has significantly decreased during the period 2008-2016 from 96% to 45% due to challenges in the procurement of vaccines in the country and antivaccination campaigns.

Conclusions:

Measles epidemic situation was caused by accumulation of a significant pockets of non-immune population.

Key messages:

- Measles epidemic situation was caused by accumulation of a significant pockets of non-immune population.
- The robust supplementary vaccination campaign among children and adult will allow to overcome measles outbreak in Ukraine.

Influenza vaccine among future health care workers: a cohort study on Italian medical students

Alessio Corradi

A Corradi[1], F Bert[1,2], E Pompili[1], D Catozzi[1], A Hordila[1], G Voglino[1], MR Gualano[1], R Siliquini[1,2]
[1]Department of Public Health Sciences, University of Turin, Turin, Italy
[2]Molinette Hospital, City of Health and Science of Turin, Turin, Italy
Contact: corradi.alessio@gmail.com

Background:

Flu vaccination rates among health workers remain low and very variable between European countries despite the recommendations. Medical schools could be the best phase to educate health workers toward flu vaccine. This study aims to evaluate flu vaccine ‘‘prejudice’’ and vaccine hesitancy in medical students (MSs).

Methods:

In 2018/19 flu season a cohort study was conducted at the School of Medicine of Turin, parallel to the flu vaccination campaign. Students were surveyed for sociodemographic variables, knowledge, attitudes and practices toward vaccination, adverse reactions, overall satisfaction toward received vaccination. Data was collected from 377 students. Multivariable logistic regressions were performed. The significance level was $p \leq 0.05$.

Results:

Females were 70% and median age was 24 (IQR 22.5-25). The 73.2% of the sample was vaccinated in the campaign, although the 60% of this had never been vaccinated before. Poor knowledge on flu vaccine, both self- and objectively assessed, was associated with lower vaccination rate (OR 0.23, $p = 0.006$; OR 0.15, $p < 0.001$ respectively). Vaccination was more likely in those who had been vaccinated in the last 3 years

(OR 9.14, $p < 0.001$). Among non-vaccinated students, most frequent reasons to not undergo vaccination was not feeling at risk of contagion (48%). Vaccine decreased flu prevalence (OR 0.33, $p = 0.039$). Among vaccinated students, the persuasion that vaccination should be mandatory for health workers (OR 5.91, $p = 0.039$) was associated with higher vaccine satisfaction score while self-diagnosis of flu was associated with a lower score (OR 0.009, $p < 0.001$).

Conclusions:

Lack of flu vaccination among health workers increases flu prevalence and multiplies possible carriers in health facilities. European Medical Schools should start yearly vaccination campaigns to promote good habits in MSs. In parallel, more must be done to teach MSs the benefits of flu vaccination and thus increasing willingness to being vaccinated.

Key messages:

- Feeling poorly informed and being poorly informed about influenza vaccine significatively decrease likeliness of vaccination in medical students. Students do not feel at risk of contagion.
- Influenza vaccine uptake is a habitual behavior that should be promoted as early as possible among European health workers, possibly during Medical School.

Assessment of the links between awareness about MI and behavior related to vaccination

Vilma Jasiukaitiene

V Jasiukaitienė[1], *I Stankutė*[1], *L Miščikienė*[1]
[1]Department of Health Management, Lithuanian University of Health Sciences, Kaunas, Lithuania
Contact: vilma.jasiukaitiene@lsmuni.lt

Backgrounds:

In Lithuania, the morbidity rate of meningococcal infection (MI) is one of the highest in the European Union. In year 2017 - 81 MI cases were reported (2.9 cases / 100 thousand inhabitants). The aim of the study - to assess the links between awareness of parents of pre-school children about meningococcal infection and behavior related to vaccination.

Methods:

Anonymous questionnaire survey was carried out in pre-school educational institutions of Kaunas city in 2019. 165 questionnaires were presented to parents (response rate 91.52%). Associations between categorical variables were measured using Chi square test. A statistically significant difference was defined when $p < 0.05$. Z criterion was used for evaluating hypothesis of variable dependence.

Results:

55.0% of respondents know that MI is caused by bacteria and it is spread by air (84.8%). 40.1% of parents indicated that they have vaccinated their children or are planning to do so. 38.0% of respondents chose not to have their children vaccinated and did not plan vaccination in the future. Answers of parents, who have vaccinated or are planning vaccination of their children, showed a statistically significant increase of awareness of the risk of MI spreading by air (44.4% and 0.0%, $p < 0.05$) and that in order to avoid the risk of MI (42.3% and 0.0%, $p < 0.05$) children need to be vaccinated following recommended vaccination plan (53.4% and 25.0%, $p < 0.05$), as well that in Lithuania MI vaccine has been included in the recommended vaccination plan in 2018 (43.7% and 12.5%, $p < 0.05$).

Conclusions:

More than half of the respondents know the pathogen of the MI, the way of it spreading, but less than half of them have vaccinated or are planning to vaccinate their children. Links have been identified between the vaccination of children and awareness of the ways of MI spreading and prevention of it.

Key messages:

- The behavior of parents with better awareness is related to decision of vaccination.
- Parents with better awareness have vaccinated or are planning to vaccinate their children from MI.

Laboratory based Influenza sentinel surveillance in Pakistan At NIC, Islamabad 2007-2017

Nadia Noreen

F Bashir[1], *K Fawad Khan*[1], *S Zafar Qureshi*[2], *F Khaudaidad*[1], *R Sonia*[1]
[1]FELTP Pakistan, Islamabad, Pakistan
[2]FGPC, ISLAMABAD, Pakistan
Contact: nadia.jamil3@gmail.com

Background:

A country-wide lab-based surveillance system for ILI and Severe Acute Respiratory Illness (SARI) with weekly sampling and reporting was established in 2008.This system was necessary for early detection of emerging novel influenza subtypes and timely response for influenza prevention and control.

Objectives:

To assess the trends of Influenza-like-Illness(ILI) and to monitor the predominant circulating strains of influenza viruses through Lab based sentinel surveillance.

Methods:

A cross-sectional study was conducted based on ten years (2007-2017) influenza surveillance data obtained from National Influenza Central Laboratory Pakistan (NICLP) from January to March 2018.Study was done from the data records and samples of suspected ILI patients and SARI patients received from all seven sentinel sites. An ILI case was defined as sudden onset of fever of ≥ 38 C$^\circ$ and cough, with onset within last 10 days, while patients with sudden onset of fever (>38 °C), cough/sore throat requiring hospital admission within 7 days were termed as SARI. Samples were tested at NICLP for confirmation of virus, typing and subtyping by RT-PCR.

Results:

A total of 15885 samples were analyzed during ten years period, out of which 3475(21.9%) were found positive for influenza virus. Among positive samples 26(0.75%) were Influenza-A (H1N1), 550(38%) were A/H3N1,550(15.9%) were A/H3N1,1587(45.7%) were A/H1N1 pdm09and 1312(37.8%) were influenza B. Males were predominant(54%).Influenza Maximum cases were reported from age group 01->12 years(66%).Virus circulation was detected throughout the year along with few cases of seasonal A/H1N1 virus during late winter(January February) and spring(March). Influenza A/H3N2 virus circulation was mainly observed during summer months (August-October).

Conclusions:

The findings of this study emphasize the need for continuous and comprehensive influenza surveillance to predict seasonal trends for vaccine development and to further fortify pandemic preparedness.

Key messages:

- The need for continuous and comprehensive influenza surveillance.
- Public health importance by pandemic preparedness.

MRSA contamination in ambulances: a systematic review

Mattia Fattorini

M Fattorini[1], *C Quercioli*[2], *G Messina*[1,3], *N Nante*[1,3]
[1]Post Graduate School of Public Health, Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[2]Hospital Val d'Elsa, Local Health Unit Tuscany South-East, Siena, Italy
[3]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
Contact: fattorini7@student.unisi.it

Background:

Methicillin-resistant Staphylococcus aureus (MRSA) is a multidrug resistant organism (MDRO) frequently involved in skin, soft tissue and bone infections. Moreover, it is one of the most frequently isolated pathogen in bloodstream infections in European countries. Because of its capacity to survive on inanimate surfaces, this microorganism could be detected not only on hospital environment, but also in other healthcare settings such as ambulances. We performed a systematic review in order to study the level of MRSA contamination in ambulances (vehicle surfaces and medical equipment).

Methods:

In March 2019 we searched studies in PubMed using the key search terms ''MRSA, ambulance''. We included different designs of studies in English.

Results:

The research yielded 18 publications: after title, abstract and full text's analysis, 9 manuscripts were included in this review. Studies were conducted from 2007 to 2018 in USA, Egypt, Poland, Germany and South Korea. Overall, the number of ambulances sampled for MRSA was 511 (min. 3-max. 150), and 64 (12.5%) resulted contaminated by MRSA. Sampling points examined for each vehicle varied from 5 to 33, for a total of 5872 (min. 39-max. 2136) samplings performed. The amount of MRSA positive samplings was 145/5872 (2.5%) (min. 1-max. 43). Stretcher resulted the most frequently contaminated fomite (29 of the 145 MRSA positive samplings, 20%).

Conclusions:

Despite MRSA prevalence is decreasing in Europe, recent studies showed how this MDRO could still be responsible of a remarkable burden in terms of attributable deaths and costs. Implementing effective sanitation procedures with a continuative monitoring of the processes is highly recommended in all the healthcare settings, including ambulances. Automated terminal disinfection of these vehicles, adopting technologies such as ultraviolet germicidal irradiation or hydrogen peroxide aerosol, could reduce bacterial contamination hosted on surfaces and medical equipment.

Key messages:

- Although the percentage of isolates of MRSA in European countries is decreasing, the burden this multidrug resistant organism in terms of mortality and costs remains remarkable.
- Ambulances must be considered as a potential reservoir of MRSA because of its ability to survive on inanimate surfaces, and adequate sanitation procedures should be frequently performed.

Evaluation of additional benefits of HPV vaccination to cervical cancer screening in France

Sophie Rousseau

S Rousseau[1], M Massetti[2], S Barre[1], H Leleu[2], J Gaillot-de Saintignon[1]
[1]Institut National du Cancer, Boulogne-Billancourt, France
[2]Public Health Expertise, Paris, France
Contact: srousseau@institutcancer.fr

Background:

The National Cancer Institute (INCa) undertook the evaluation of the expected impact of HPV vaccination in the context of the recent marketing of nonavalent vaccine (Gardasil®9) and the implementation of organized screening (OS) of cervical cancer (CC) in France.

Methods:

The study is based on a microsimulation model that replicates the natural history of CC. A cohort of 14-year-old women is generated and followed until death. Others HPV-infection related diseases (condyloma, anal cancer, penile cancer and oropharynx cancer) are not modelled. Different strategies were compared with the current vaccination coverage rate (VCR) of 21.4% (2017): impact of increased VCR alone and increased VCR combined with correction of inequalities (CI). Results are presented according to two hypotheses for the duration of protection offered by the vaccine (limited to 20 years and lifelong) and according to two hypotheses for price of the vaccine (French price and average European prices).

Results:

The incremental cost-effectiveness ratio (ICER) was less than 15 000 euros per QALY (quality-adjusted life year) in all the assessed strategies. For each 14-year-old women cohort, 85% VCR with CI would prevent at least: 2 546 conations, 2 347 precancerous lesions CIN 2 / 3 diagnosed, 377 CCs, 139 deaths per CC (20 years vaccine protection). Scenarios based on increasing VCR with CI are the most cost-effective.

Conclusions:

The study quantifies the increased risk of CC-related outcomes associated with current sub-optimal VCR and the possible investment to implement actions in order to improve the efficiency of the current strategies and tackle health inequalities (communication campaign, actions toward underserved women).

Key messages:

- Improving HPV vaccination uptake is a cost-effective measure, even considering only the cervical cancer prevention.
- Including health inequalities participation in modeling is crucial as underserved women are both less vaccinated and screened.

Hospital acquired infection, evaluation of point of prevalence in a 147 beds italian hospital

Francesco Gori

F Gori[1], N Vonci[1], G Santoriello[2], C Quercioli[2], G Messina[1,3], S Sancasciani[2]

[3]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
Contact: francescogori24@gmail.com

Background:

Hospital Acquired Infections (HAI) have become a public health priority worldwide, leading to higher medical costs, prolonged hospital stays, and increased mortality. The point of prevalence analysis (PPA) of HAI and antibiotics (ATB) consumption is extremely relevant for its social and economic impact. Aim of this study is to evaluate the prevalence of HAI and to analyze ATB consumption in 147 beds hospital.

Material and Methods:

This prevalence study was conduced on March 23, 2018, we analyzed the clinical documentation of 78 patients hospitalized in the Hospital of Val D'Elsa, Siena, Italy and searched for evidence of HAI and for all indication of ATB therapy in all hospital wards. HAI were defined according to guidelines of European Centers for Disease Control and Prevention (ECDC 4.2) using Stata 12.

Results:

We analyzed a total of 78 patients (51,3% female), average age was 71,6 (sd ± 23,4) years, mean lenght of stay 7,2 (sd ± 7,9) days. Patients included in the study were recovered mostly in General Medicine ward (62,8%); 23% of patients underwent surgery. Fifty-one point three of patients had Peripheral Venous Catheter, 17,9% Central Venous Catheter and 47,4% Urinary Catheter. Three infections were discovered (PPA 3,8%); 2 HAIs were found in Medicine ward, the third one in the Intensive Care Unit. The chi-square test did not show statistically significant differences with the last year's results in the same wards ($p = 0.3305$). Fifty-four percent of all patients received ATB, the most used class were third generation Cephalosporines (50%), followed by Carbapenems (19%) and Fluoroquinolones (7%).

Conclusions:

PPA of HAI was 3,8%, comparable to last year's (3,5%). This is a positive result when compared to regional and national point prevalence study realized by ECDC in 2012 (6,2% in Tuscany Region, 6% in Italy). Our analysis showed that ATB consumption was quite high: and it is in agreement with those provided by the Tuscany Region.

Key messages:

- in our hospital we report an excellent result about the pint of prevalence of hospital acquired infections 3,8%.
- The antibiotics consumption in our hospital is quite high, the most frequently used antibiotic class is the third generation Cephalosporines.

Increasing awareness about psittacosis among bird owners

Annet van t Westeinde

T Overmars-Marx[1]
[1]GGD IJsselland, Zwolle, Netherlands
Contact: a.vant.westeinde@ggdijsselland.nl

Background:

Visitors of bird fairs and bird owners in general are at risk of becoming infected by Chlamydia psittaci bacterium. This bacterium is mainly found in birds and can be transmitted to humans. The knowledge about psittacosis is limited among the general public, bird owners and even among doctors.

Awareness to health problems regarding psittacosis, is important. By increasing this awareness among bird owners we encourage them to report these health problems and bird contact to the general practitioner. Experience shows that it is difficult to reach this particular group. The aim of this study was to gain more insight in the characteristics of bird owners to develop methods for providing appropriate information. This information aims to increase awareness regarding psittacosis.

Methods:

The research adopted a qualitative approach and in depth interviews were held with sixteen bird owners using a semi-structured interview guide. The data collected was analysed using thematic analysis.

Results:

Four themes were identified: social network related to birds, relationship with birds, awareness of risks and symptoms of psittacosis, information channels.

Conclusions:

Most of the study participants were hobby breeders. They experience a strong connection with their birds and are experts in this field. In general they feel healthy. The bird owners are unaware of the fact they risk a disease as a consequence of their favourite hobby. However, they seem to be open for advice related to their health. It is recommendable to provide information from a near-by environment (e.g. through internet or at the local bird club) and use credible ambassadors. Increased awareness on the symptoms of psittacosis can be reached if appropriate information is received by bird owners. This might lead to more reports at the general practitioner and therefore prevents severe cases of psittacosis.

Key messages:

- Most bird owners were unaware of the health risks related to their birds.
- To prevent severe cases of psittacosis it is important to provide information from a near-by environment and to use credible ambassadors.

Vaccine hesitancy among parents in the general population in Sicily (South Italy): A survey study

Maria Fiore

M Ferrante[1], *A Cristaldi*[1], *L Cormaci*[2], *MG Falla*[2], *P Zuccarello*[1], *G Oliveri Conti*[1], *M Fiore*[1]
[1]University of Catania, Catania, Italy
[2]Specialization School of Hygiene and Preventive Medicine, University of Catania, Catania, Italy
Contact: mfiore@unict.it

Background:

Vaccine hesitancy (VH) has become the focus of growing attention because of decreased vaccination rates and increased emergency department use, morbidity, and mortality. VH has not been deeply studied in Sicily. The aim of this study was to estimate the prevalence of VH among parents and to investigate the potential determinants.

Methods:

We performed a survey from 1 March to 1 June 2018, using a random sample of parents who reported on median 10 year-old children. The parents were recruited in pediatrician's offices and elementary schools. Information pertaining to socio-demographic characteristics, sources of information regarding vaccination and VH was collected. VH was calculated using the Parents Attitudes about Childhood Vaccines (PACV) questionnaire. Associations between VH and predictors were tested using Multivariable Logistic Regression.

Results:

In total 471 questionnaires were collected, 77.7% of respondents were mothers. Based on the PACV 100-point scale, 73.2% (95% CI: 69.0-77.2) of parents had a 0 to <49 score (low level of VH); and 26.8% (95% CI: 22.8-31.0) had a score of 50 and higher (high level of VH). Internet (66.9%, 95% CI: 62.4-71.1) was the main source of information on vaccination followed by television (29.1%, 95% CI: 25.0-33.4). In the bivariate analyses, VH was associated with education, marital status and occupation, but not with gender and age of parents. In multivariate analyses, highly educated (ORadj = 0.297, 95% CI = 0.141-0.626) and married (ORadj = 0.457, 95% CI = 0.213-0.977) parents were more prone to be nonhesitant, but not so unemployed parents (ORadj = 1.787, 95% CI = 1.083-2.956).

Conclusions:

The prevalence of VH among the Sicilian parents was comparable with other populations. These results could be an important starting point to support the implementation of effective vaccination strategies.

Key messages:

- Implement interventions and strategies to further understand the issue of VH, to restore trust in authorities and vaccines.
- Suggest strategies that could improve childhood vaccination rates.

Risk factors of healthcare associated infections: prevalence surveys over five years

Hela Ghali

H Ghali[1], *A Ben Cheikh*[1], *S Bhiri*[1], *S Khefacha Aissa*[1], *L Dhidah*[1], *M Ben Rejeb*[1], *H Said Latiri*[1]
[1]Department of Prevention and Security of Care, Sahloul University Hospital, Faculty of Medecine of Sousse, University of Sousse, Sousse, Tunisia
Contact: yasminebenrejeb@hotmail.com

Background:

Healthcare associated infection (HAI) is alarmingly increasing in low income settings. In Tunisia, the burden of HAI is still not well described. We aimed to analyze risk factors independently associated with HAIs in hospitalized patients in Sahloul Hospital for the last five years.

Methods:

We conduct every year a prevalence survey, as part of the program for the prevention and control of HAI at Sahloul Hospital. It is a cross-sectional study of one-day prevalence with a single pathway. All departments were included in the survey, except emergency and hemodialysis services due to their very short length of stay. Data collection was carried out using NosoTun plug (national HAI prevalence survey). Logistic regression was performed to identify independent risk factors of mortality among infected patients with p value less than .05.

Results:

Over five years, prevalence of HAI ranged from 11.4% in 2014 to 7.1% in 2018. In 2014, independent risk factors of HAIs were the use of peripheral venous catheter, central venous catheter, and undergoing a surgery. Intensive care units and surgical departments were independently associated with the occurrence of HAIs. In 2015 and 2016, in addition to the factors already mentioned, antibiotic therapies for the last six months as well as parenteral feeding were also found as independent risk factors. In both 2017 and 2018, intrinsic factors were found in multivariate analysis; in fact diabetes as underlying disease was independently associated with HAIs.

Conclusions:

Identifying risk factors that contribute to develop HAIs may support the implementation of strategies for their prevention, therefore maximizing patient safety.

Key messages:

- Identifying risk factors for HAIs may improve patient safety.
- Insertion of medical devices was the main risk factor for patients over the five years.

Participatory action research for global antibiotic stewardship network in CPLP: mixed-method study

Luis Lapao

MR Maia[1,2], *LV Lapão*[1]
[1]Global Health and Tropical Medicine, Institute of Hygiene and Tropical Medicine, NOVA University of Lisbon, Lisbon, Portugal
[2]School of Social Sciences and Humanities, NOVA University of Lisbon, Lisbon, Portugal
Contact: luisvlapao@gmail.com

Background:

Antibiotic stewardship services (ABS) contribute to antibiotic resistance (AR) global monitoring. Aiming at co-implement an ABS network within the Portuguese-speaking setting (CPLP), by enabling the evidence translation and second opinion between the countries, we surveyed Cape Verdean (CV) health professionals (HP) perceptions about AR prevention and control, assessing ABS opportunities.

Methods:

A Design Science with Participatory Action Research establishes a contextualized ABS process. This mixed-method study addressed the first 2 stages, the problem and objectives. Quantitative study considered the HP's answers (56 HP; 2 hospitals) to a questionnaire, about their perception on AR and ABS. Qualitative study set-up 10 open-ended structured interviews, clinical shift observation in 2 pilot-services (1 hospital), and meetings with key-elements for ABS, including leadership.

Results:

Key-stakeholders for ABS multidisciplinary teamwork were identified. Preliminary results are: 1. HP reveal some knowledge but lack of awareness on AR and ABS (eg. 34% don't recognize the AR local threat); 2. The absence of guidelines and lack of access to key-information affect prescribing confidence (eg. only 46% HP consider microbiology results in deciding antibiotherapy); 3. Priorities for a pilot service are the lack of qualified HP, the need to optimize material resources management and stock procurement, and the need for better access to patient's clinical and prescription information; 4. Digital resources and telemedicine system can be facilitators. Top-down communication and support are essential for the ABS process sustainability.

Conclusions:

A Global ABS network can be important in promoting prevention and effective control of AR, reducing differences between the CPLP countries. In CV, an educational program to support the co-design of ABS service and a decision-support information system are identified priorities. Digital health, like telemedicine, can be ABS facilitators.

Key messages:

- The implementation of a Global Antibiotic Stewardship network, aiming at reducing Portuguese-speaking Countries differences, could be leveraged by a Participatory Action Research process.
- An educational program, a decision-support information system and the telemedicine are key for the Global Antibiotic Stewardship network implementation success.

Evaluating latent tuberculosis testing and treatment programme for new migrants in South East England

Priyamvada Paudyal

P Paudyal[1], *A Mason*[1,2], *A Gedi*[2], *B Purcell*[2]
[1]Brighton and Sussex Medical School, Brighton, UK
[2]South East, Public Health England, Horsham, UK
Contact: p.paudyal@bsms.ac.uk

Background:

Tuberculosis (TB) cases in England often originate from high burden TB countries due to 'reactivation' of the latent TB infection (LTBI), an asymptomatic and non-infectious phase lasting years. 5,137 TB cases were notified in England in 2017, and 71% of these patients were born outside the UK. This mixed-method study evaluated the implementation of the four LTBI testing and treatment programme for new migrants in South East (SE) England.

Methods:

A retrospective database (May 2016-Feb 2018) review was undertaken to identify LTBI cases using multiple data sources; LTBI testing laboratories, LTBI programmes, and the national TB team at Public Health England. In addition, a survey questionnaire was emailed to 51 stakeholders (45% response rate) and five in-depth interviews were conducted with LTBI programme leads/TB nurses to explore the challenges of the programme. Quantitative data were analysed using descriptive summary statistics and qualitative interviews were analysed using thematic content analysis.

Results:

Of the 5931 eligible patients, 40 % (n = 2391) accepted the LTBI test and 13.4% (n = 321) tested positive. 93.1% (n = 299) of the positive patients were referred for treatment and 63.8% (n = 191) of these accepted the treatment. The programme also picked up 18 active TB cases, an unexpected incidental finding. Results from the survey and the interviews identified laboratory arrangements, workforce, and data collection/management as the greatest challenges for the LTBI programme. Patient focused care, cultural understanding, success in testing/treating migrants, and raising awareness amongst professionals/communities were highlighted as achievements of the programme.

Conclusions:

This study found that LTBI programmes in SE England are in line with national expectations and other LTBI programmes in England. The study recognises the achievements and good practice of the LTBI teams in SE England and identifies key barriers to improve the service for the future.

Key messages:

- Data collection and management is the biggest challenges of the LTBI programmes in SE England.
- The LTBI programmes in SE England are in line with national expectations.

Prevalence survey of healthcare associated infections in a large teaching hospital

Fulvio Castellani

F Castellani[1], *D Barbato*[1], *A Angelozzi*[1], *C Isonne*[1], *V Baccolini*[1], *G Migliara*[1], *C Marzuillo*[1], *C De Vito*[1], *M De Giusti*[1], *P Villari*[1]
[1]Department of Infectious Diseases and Public Health, Università La Sapienza di Roma, Rome, Italy
Contact: fulvio.castellani@uniroma1.it

Background:

Healthcare Associated Infection (HAI) is the most frequent adverse event in healthcare settings. It is associated with an increased mortality and antimicrobial resistance, prolonged hospital stays and consistent financial loss for the healthcare systems. The objective of this study was to estimate the burden of HAIs and antimicrobial use in the Teaching Hospital Policlinico Umberto I (THPUI) of Rome to identify the most critical areas for interventions.

Methods:

Data were collected according to the most recent ECDC Point Prevalence Survey protocol in November 2018. Descriptive statistics for all variables were calculated. Univariate analysis was used to assess possible associations between variables and HAIs. Variables with a significance level of $p < 0.25$ were included in a multiple logistic regression model.

Results:

A total of 799 patients were included in the analysis; of these, 13.3% presented at least one HAI. Bloodstream infection was the most common, accounting for 30.9% of the total infections. Globally, 125 microorganisms were isolated, with Enterobacteriaceae being the most frequent (32%). At the time of the survey, 49.1% patients were receiving antimicrobial therapy. The multivariate analysis showed a significant association between HAI and use of medical devices (OR = 34.30,IC95%:3.69-318.66), length of stay (OR = 1.01, IC95%:1.00-1.02) and the exposure to prophylactic antimicrobial therapy (OR = 0.23, IC95%:0.11 -0.47).

Conclusions:

Our HAI prevalence was higher than the European standard (6.7%). This highlights the need of implementing targeted measures to prevent and control HAIs and a continuous monitoring to evaluate the effectiveness of such interventions. Another step could be the elaboration of a survey to investigate the knowledge, attitudes and practices of healthcare workers towards HAIs in order to raise awareness, enhance surveillance strategies and promote educational interventions.

Key messages:

- It was important to quantify the burden of HAIs in the THPUI in order to identify the main areas for interventions.
- Several activities will be implemented to contain this problem.

Knowledge of Romanian young women regarding HPV and cervical cancer

Monica Brinzac

M Brinzac[1], A Coci[1], V Ionaşcu[1]
[1]Cluj School of Public Health, Cluj Napoca, Romania
Contact: monica.brinzac@publichealth.ro

Romania has the highest prevalence of cervical cancer in Europe. Cervical cancer is ranked the fourth deadliest cancer and the first among women aged between 15-44 years. In Romania, this type of cancer has 4443 new cases annually and is responsible for 1909 deaths. Lack of sexual education was linked to the increased prevalence rates of cervical cancer. Romania has a two-fold incidence rate than Finland, Luxembourg and France, countries which have sexual education courses.

HPV is the most prevalent risk factor for cervical cancer and this disease is the third most common cancer among women and the second most common among women aged between 15-44 years.

The design of the present study is quantitative as the data was gathered through an online questionnaire. The target group was selected through some pre-established parameters based on the previous searches on Facebook and Google like age, sex, HPV, vaccine, immunization, cervix, cervical cancer. The sample was represented by all the women that reach the parameters aged between 18- 24 years. The results show the knowledge on HPV, HPV vaccination and cervical cancer to be good as for all the questions more than half of the sample had an adequate understanding. In contrast, the overall tendency of the sample was for most of them to be aware of the existence of the mentioned diseases, of the testing process and vaccine existence, but then to lose their expertise when having to give details on the concepts reminded. This trend was noticed in all section as the first questions assessed their awareness of the HPV, cervical cancer, Pap- smear and vaccination, while the following needed a more comprehensive knowledge (i.e. 94.5% of the sample heard of Pap-smear while only 58.7% what it is).

The results have highlighted the gap in the knowledge of Romanian women and the need of campaigns and policies targeting this area. This study can form a basis for the development of such programs as it emphasizes the underdeveloped areas.

Key messages:

- Presenting a snapshot of the knowledge of young adult women on HPV and cervical cancer.
- Putting the groundwork for future studies and policies.

Analysis of risk factors for occupationally acquired HBV, HCV, HIV infections in Polish paramedics

Katarzyna Topczewska

Katarzyna Topczewska[1], Maria Gańczak[1]
[1]Department of Epidemiology and Management, Pomeranian Medical University, Szczecin, Poland
Contact: katarzyna.topczewska@pum.edu.pl

Background:

Paramedics constitute a group of professionals constantly exposed to potentially infectious biological material through close contacts with patients, possibly resulting in occupationally acquired infections.

Objectives:

To assess the prevalence and to analyze selected risk factors for occupationally acquired HBV, HCV and HIV infections among Polish paramedics.

Methods:

Between December 2018-April 2019 a cross-sectional serosurvey was conducted in 6 randomly selected ambulance stations in the West Pomeranian region of Poland with the use of an anonymous questionnaire. Serum samples were assessed for anti-HBc total, anti-HCV, anti-HIV with the use of 3rd-generation testing methods.

Results:

Response rate was 83%; 141 participants (82% males, median age 33 years, median length of practice 11.9 years) agreed to participate. Anti-HBc were found in 7% participants, none of infected individuals was aware of an infection; no anti-HCV/anti-HIV positive paramedics were recognized. Risk factors for occupationally acquired infections were as follows: 5.1% paramedics were not vaccinated against HBV, 18.3% sustained $\geq$ 1 sharps injury in the preceding year (44.4% of incidents were not reported), 95.6% irregularly used masks/goggles, 6.2% used gloves irregularly (the lack of availability was the most commonly stated reason), 5.1% had never participated in infection control training, 61.6 % did not use safety engineered devices at work, 52.2% reported recapping a needle in the last 12 months. The risk of a single exposure to HBV was correctly defined by 40.2 % of participants, to HCV - by 33.0%, to HIV - by 28.3%.

Conclusions:

Most risk factors for occupationally acquired blood-borne infections among Polish paramedics are modifiable. Unsatisfactory knowledge about the occupational exposure risks and poor compliance with infection-control procedures call for better risk recognition and assessment to reduce HBV, HCV and HIV infections in this group of health professionals.

Key messages:

- Paramedics showed detectable markers of HBV infection; individuals with not recognized occupationally acquired infection could be a source of infection for patients.
- Existing policies should be reinforced, and better surveillance for occupational risks should be instituted to minimize occupational blood borne infections among paramedics.

Strategies to achieve HPV-related disease control in Italy: results from an integrative approach

Chiara de Waure

A Acampora[1], A Grossi[1], V Colamesta[1], A Barbara[1], A Causio[1], GE Calabrò[1], S Boccia[1], A Cicchetti[2], C de Waure[3]
[1]Institute of Public Health, Catholic University of Sacred Heart, Rome, Italy
[2]School of Health Economics and Management, Catholic University of Sacred Heart, Rome, Italy
[3]Department of Experimental Medicine, University of Perugia, Perugia, Italy
Contact: chiara.dewaure@unipg.it

Background:

Vaccination against Human Papilloma Virus (HPV) might allow controlling HPV-related diseases but coverage in Italy is far from the optimal goal. This project aimed at identifying strategies to promote HPV vaccination in Italy.

Methods:

an integrative approach including a systematic review and a two-step panel consultation was used to identify strategies for improving coverage among adolescents who are already target of the national campaign and promote vaccination in further targets. The systematic review followed PRISMA recommendations and the panel consultation relied on the administration of questionnaires in the first step and on a televoting system during a consensus conference in the second one. Ten experts were involved belonging to Gynecology, Public Health, General Practice, Pediatrics and Consumers. Recommendations relied on a set of criteria drawn from the Evidence to Decision framework.

Results:

The systematic review led the identification of three main strategies to improve coverage respectively based on reminds, education and multicomponent approaches. Following the evaluation of selected criteria, namely relevance of benefits, evidence strength, feasibility, equity, acceptability and costs, a strong recommendation was formulated on the use of reminds tailored to vaccine recipients or their parents whereas a moderate one was developed on the use of reminds directed to health professionals. A moderate recommendation was released on the implementation of multicomponent interventions. The panel consultation also supported the elaboration of a strong recommendation on the promotion of vaccination among women treated for HPV-related diseases, fertile women not yet vaccinated and 25 years old women. Catch-up initiatives, in particular among women and men 18 years old, were also identified as strongly recommendable.

Conclusions:

This project led to identify several valuable strategies to strengthen HPV vaccination at national level.

Key messages:

- Using reminds tailored to vaccine recipients or their parents is strongly recommended while using reminds directed to health professionals and multicomponent interventions are moderately recommended.
- It is strongly recommended to promote HPV vaccination among women treated for HPV-related diseases, fertile women not yet vaccinated and 25 years old women.

How to reach high behavioral riskgroups for HBV-vaccination: combining offline and online strategies

Annemarie Meiberg

AT Urbanus[1], *AE Meiberg*[1]
[1]CIb, RIVM, Bilthoven, Netherlands
Contact: annemarie.meiberg@rivm.nl

Issue:

Since 2002, the Netherlands started a hepatitis B-vaccination program targeted at high behavioral risk groups in absence of a universal vaccination policy (implemented from 2011 onwards). The Public Health Services (PHS) offer free HBV-vaccination to sexworkers (SW) and men who have sex with men (MSM). In order to increase vaccination coverage and adherence a combination of offline and online strategies was used.

Description:

In 2002 the HBV-program started to reach risk groups by offline outreach activities like visiting sauna's, brothels, festivals etc. In addition targeted campaigns were developed: posters and incentives were used at outreach locations. Gradually, reaching the riskgroups at location became less effective and more costly, therefore online outreach became more important: targeted campaigns are conducted via social media, online dating platforms and commercial sex websites. These campaigns refer to websites with sexual health information, tailored advice and an online module to schedule vaccination appointments.

Results:

In 16 years' time, the program reached over 62,000 MSM and 23,000 SW with a combination of offline and online strategies. Nowadays, PHS nurses organize each year around 70-80 regional (online and offline) outreach actions for MSM and around 30-35 for SW. in 2017-2018 9-13% of the first vaccinations among MSM and SW was facilitated by the online appointment module. In addition, each year PHS are motivated to develop innovative plans in order to increase vaccination coverage such as informative meetings for MSM migrants with a festive touch, and in-depth research in how to reach male and female SW at home.

Lessons:

Combining targeted online and offline strategies in order to reach the risk groups for vaccination has been successful over the past 16 years. Each year about 4,000 MSM and 1,000 SW receive their first HBV-vaccination thanks to constant commitment and creativity of enthusiastic health professionals for new approaches.

Key messages:

- Combining targeted online and offline strategies in order to reach the risk groups for vaccination has been successful.
- Encouraging innovative plans is succesful in reaching high behavioral risk groups for vaccinations.

Surveillance of healthcare-associated infections in a Tunisian university hospital

Asma Ben Cheikh

H Hannachi[1,2], *A Ben Cheikh*[1,2], *S Bhiri*[1,2], *H Ghali*[1,2], *S Khefacha*[1,2], *L Dhidah*[1,2], *M Ben Rejeb*[1,2], *H Said Latiri*[1,2]
[1]Université de Sousse, Faculté de Médecine de Sousse, Sousse, Tunisia
[2]Department of Prevention and Security of Care, Hospital of Sahloul, Sousse, Tunisia
Contact: asmasmams@yahoo.fr

Introduction:

Healthcare -associated infections has become a worldwide public health problem. The aim of this study was to estimate the incidence of healthcare- associated infections in a university hospital of Tunisia.

Methods:

This was a cohort study conducted in six intensive care units in a university hospital of Tunisia during three months (from august to October 2018). Data was provided from patients' files. Data entry and analysis was done using SPSS version 22. Multivariate analysis was used in order to identify independent risk factors for healthcare associated infection.

Results:

A total of 202 patients were enrolled in this study. The incidence rate of healthcare-associated infections was 53,96%(109/202). The ratio infection/infected was estimated to 1.65(109/66).

The incidence of multi-drug resistant pathogens was 21,28% (43/202). The most common resistant pathogens included pseudomonas aeruginosa resistant to cefdazidime in 13,76%(15/109) followed by those resistant to extended spectrum cephalosporin 11.92% (13/109), followed by carbapenem-resistant acinetobcater baumanii 6,42%(7/109) then by carbapenem resistant pathogens and enterococcus resistant to vancomycin 2.75%(3/109) and finally staphylococcus aureus resistant to methicillin 2.1%(2/1.83). The multivariate analysis showed that long duration of central line catheterisation (RR = 7.44; 95%CI[2.79-19.82]), tracheotomy(RR = 8.61;95%CI[2.09-35,39]) and length of stay (RR = 1.08; 95%CI[1.04-1.13]) were found as independent risk factors for healthcare -associated infection.

Conclusions:

The emergence of mutli-drug resistant pathogens needs to be deeply studied and effective measures have to be taken in order to detect and prevent transmission of resistant strains and/or their resistance determinants, especially those with phenotypes having the fewest viable treatment options.

Key messages:

- The incidence of healthcare associated infection in the intensive care unit was high.

- Effective measures have to be taken in the intensive care unit to detect and prevent transmission of resistant pathogens.

Community engagement in public health emergency preparedness

Barbora Kinross

J Takacs[1], M Ciotti[1], S Tsolova[1], E Wiltshire[1], A Baka[1], J Kinsman[1,2,3], D de Vries[4], L Cremers[4], M Rios[4], J Angrén[5]
[1]ECDC, Solna, Sweden
[2]Epidemiology and Global Health Unit, Umeå University, Umeå, Sweden
[3]Karolinska Institutet, Solna, Sweden
[4]University of Amsterdam, Amsterdam, Netherlands
[5]Public Health Institute, Solna, Sweden
Contact: Barbora.Kinross@ecdc.europa.eu

Background:

Communities that could be affected by infectious disease outbreaks are increasingly recognised as resources that may be effectively utilized by the authorities during public health emergencies.

Methods:

This case study project, aiming to identify synergies between communities and authorities, was based on qualitative sources of evidence, including document and media review, stakeholder mapping, interviews and FGDs (N = 137). Four countries were selected for inclusion: Spain and the Netherlands on the basis of emerging tick-born disease incidents; Iceland and Ireland on the basis of acute gastroenteritis outbreaks.

Results:

In the Netherlands and Spain strong synergies were identified in tick surveillance activities, and the value of pre-existing networks of interest groups for preparedness and response activities was recognised. The Icelandic norovirus event was unexpected and fast-moving, while VTEC in Ireland is a familiar and slower-burning challenge. As a relatively common disease in Ireland, VTEC-protocols are closely followed, while a generic all-hazards approach was taken in Iceland. There was considerable community support in the responses in both countries., and in Iceland community representatives also actively participated in producing institutional post-event evaluations.

Conclusions:

An over-riding principle emerging from this study is that an informed, at-risk community understands the challenges to adopting effective preventive practices for themselves better than anyone. Additional good practices included the utilisation of pre-existing stakeholder networks for information dissemination; and of monitoring community perceptions of any public health incident, including through social media, in order to identify and manage misperceptions. Efforts to build on the community engagement activities that are already in place in the four countries could contribute to better preparedness planning and more efficient and timely responses in future outbreaks.

Key messages:

- Recognise the community as a real partner in outbreak preparedness, response, and recovery.
- Optimise communications with communities who may be affected by outbreaks.

Incidence study of surgical site infections in a large University Hospital in Rome, first results

Doriana Vallone

D Vallone[1], M Di Pumpo[1], A Gentili[1], A Tamburrano[1], F Berloco[2], MI Corbo[2], A Cambieri[2], G Damiani[1,2], W Ricciardi[1,2], P Laurenti[1,2]
[1]Institute of Public Health, Section of Hygiene, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Hospital Health Management, Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Rome, Italy
Contact: doriana.vallone@guest.policlinicogemelli.it

Background:

Surgical Site Infections (SSI) represent about a quarter of healthcare associated infections (HAI), increase the risk of mortality and hospital stay and extend healthcare costs. The aim of this work is to evaluate the incidence of SSI in patients undergoing surgical procedures of Hospital Units in the Fondazione Policlinico A. Gemelli IRCCS (FPG).

Methods:

This descriptive observational monocentric study has a 30-months duration: the first phase was conducted between July 2018 and March 2019. Patients undergoing abdominal surgery procedures were enrolled. Active infection surveillance was performed, according to the ECDC, during the hospital stay and the surgical outpatient visits. We also performed a post-discharge surveillance (PDS) at 30 days (or 90 days if an implant has been inserted), through a telephone interview, made by a medical doctor resident in Public Health.

Results:

During the first phase were enrolled 431 procedures in 2 Hospital Units, about emergency and hepatobiliary surgery. There were 53 cases of surgical site infection (SSI) highlighted in these procedures. Therefore, SSI's were reported in 12.09% of the procedures. In particular, in 6.28% of cases, SSIs were diagnosed during the hospital stay. The results of this study showed statistically significant differences ($p < 0.005$) in incidence rate of emergency (10,70%) and hepatobiliary tract (13,17%) procedures. The average hospital stay was significant higher ($p < 0.001$) in patients who developed an SSI (17.27 days) than in patients without SSI (4.89 days).

Conclusions:

These preliminary results show that the incidence rate of SSI for gastrointestinal procedures is similar to other European Countries (9.6%). The Hospital Health Management of FPG take care to the surveillance of hospital infections and monitor the correct application of the procedures, in line with the standards defined by Joint Commission International for guarantee high level in patients' care.

Key messages:

- Performing a survey to measure the incidence of surgical site infections for surgery procedures is very important to define it and to improve surveillance systems of hospital infections in FPG.
- Active surveillance of surgical site infections may allow to enhance appropriate preventive measures.

Influenza vaccination campaigns targeted at healthcare workers:results of four hospitals in Rome

Marcello Di Pumpo

A Tognetto[1], A Abbondanzieri[2], G Cerone[2], M Di Pumpo[1], A Nardi[3], L Paglione[3], E Franco[2], G La Torre[3], GB Orsi[3], P Laurenti[1,4]
[1]Section of Hygiene, Institute of Public Health, Catholic University of the Sacred Heart, Rome, Italy
[2]Department of Biomedicine and Prevention, University of Rome Tor Vergata, Rome, Italy
[3]Department of Public Health and Infectious Diseases, Sapienza University of Rome, Rome, Italy
[4]Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy
Contact: dipumpomarcello@gmail.com

Background:

Seasonal influenza vaccination (SIV) of health care workers (HCWs) is well recognized as a public health measure that can protect both HCWs from infection and patients from the risk of influenza complications. Nevertheless, vaccination coverage rates among this specific population result generally lower than the recommended target. With our study, we aimed to describe the activities and the outcomes of four different SIV campaigns targeted at HCWs and organized during the season 2018/2019 in four hospitals in Rome.

Methods:

A cross-sectional study involving four teaching hospitals was performed. The collected data were synthetized into a set of descriptors and indicators, validated through a previous study that had involved the same Centers.

Results:

The Medical Directorates, in collaboration with the University Hygiene and Public Health Units of the four hospitals organized different strategies: Hospital 1, 3 and 4 realized educational courses for HCWs and actively promoted the campaigns through e-mail invitations to all HCWs. As for the access to vaccination, all the hospitals provided a dedicated unit for SIV; Hospital 1 and Hospital 4 organized also on-site vaccination sessions in the hospital wards, that required a large number of staff. The vaccination coverage rates resulted: 22.37% in Hospital 1, 18.10% in Hospital 4, 9.28% in Hospital 2 and 8,51% in Hospital 3.

Conclusions:

Our results demonstrate that multi-activity campaigns, involving education, promotion and easy access to vaccination constitute an effective approach to reinforce the value of SIV. Our findings suggest that on-site vaccination may play a key role in determining a higher vaccination coverage.

Key messages:

- Multi-activity vaccination campaigns, involving education, promotion and easy access to vaccination constitute an effective approach to reinforce the value of seasonal influenza vaccination for HCWs.
- On-site vaccination may play a key role in determining a higher vaccination coverage.

The Knowledge on antibiotics and antimicrobial resistance among Polish medical students

Beata Mazińska

T Sobierajski[1], *M Wanke-Rytt*[2], *B Mazińska*[3], *K Karpierz*[2], *W Hryniewicz*[3]
[1]Faculty of Applied Social Sciences and Resocialisation, University of Warsaw, Warsaw, Poland
[2]The Medical University of Warsaw, Warsaw, Poland
[3]Department of Epidemiology and Clinical Microbiology, National Medicines Institute, Warsaw, Poland
Contact: b.mazinska@nil.gov.pl

Background:

Antimicrobial resistance (AMR) is one of the biggest threats to public health worldwide, compromising ability to treat infections. Medical students as a future doctors will have an important role to play in preventing the spread of antibiotic resistance. The aim of this study was to analyse the knowledge and attitudes of Polish medical students towards antibiotics and AMR.

Methods:

A questionnaire containing 24 questions, on medical students' knowledge, attitudes and perceptions of antibiotic prescribing and antibiotic resistance was developed. The survey was conducted in May-June 2018 among medical students of Medical University of Warsaw at various years of their studies.

Results:

The study group consisted of 291 students (70% women, 30% men). Forty six of the students had used antibiotics within the previous 12 months. The prevailing reasons for taking an antibiotic were: pharyngitis (25%), bronchitis (12,8%), sore throat (12%), cough (8.3%), pneumonia (7.9%), urinary tract infection (7.6%), cold (6.6%). Ninety-two percent of the respondents considered AMR to be a significant problem, and 7.9% stated it will become in the future. Four percent of respondents believed that antibiotics are effective in treating common cold. The majority of students (83.5%) expressed the opinion that doctors often prescribe an antibiotic without need. Most respondents think that too frequent prescription and low awareness of the consequences of their overuse have an impact on the rise and spread of antibiotic resistant bacteria. The vast majority of respondents (80%) declared that university studies enabled the gaining of a wider knowledge about the use of antibiotics. The vast majority of respondents (92.4%) indicated a willingness to extend their knowledge on antibiotic use.

Conclusions:

Medical students are aware that AMR is a growing problem resulting in diminishing treatment options. The results of the study should be taken into future education programs.

Key messages:

- Medical students have a good understanding of the health risk of AMR but consider antibiotics for viral infections.
- More training on rationale antibiotic use included in the curriculum is warranted.

MenACWY vaccination decisions in the Netherlands: the role of risk perceptions

Marion de Vries

M de Vries[1,2], *L Claassen*[2], *M te Wierik*[1], *F Coban*[1], *D Timmermans*[3,4], *A Timen*[1,5]
[1]Centre of Infectious Disease Control, RIVM, Bilthoven, Netherlands
[2]Centre of Environmental Safety and Security, RIVM, Bilthoven, Netherlands
[3]Department of Public and Occupational Health, VU University Medical Centre, Amsterdam, Netherlands
[4]RIVM, Bilthoven, Netherlands
[5]Athena Institute, VU University, Amsterdam, Netherlands
Contact: marion.de.vries@rivm.nl

Background:

The Netherlands experiences an unprecedented increase in meningococcal W infections. A national catch-up menACWY vaccination campaign started in October 2018, covering birth cohorts 2001-2005. To understand menACWY vaccination decisions, our study reports on perceptions of risks and their influence on menACWY vaccination intentions during an ongoing outbreak of meningococcal infections.

Methods:

Online surveys were administered in September 2018 among adolescents (AD) targeted for menACWY vaccination (N = 3036) and parents (PA) of these adolescents (N = 3002). Following a mental models approach, survey items addressed knowledge and beliefs of meningococcal disease, the menACWY vaccination and vaccinations in general, and menACWY vaccination intention. Random Forest Analyses were conducted to identify those knowledge and beliefs that strongest predict vaccination intention.

Results:

The response was 52.8% (N = 1603) in AD and 57.1% (N = 1784) in PA. 71% Of AD and 83% of PA indicated a positive vaccination intention. Most respondents perceived meningococcal disease as a severe disease with possible deathly consequences and were aware of transmission routes. Some misbeliefs of vaccines were rather strongly represented, with respectively 35% of AD and 45% of PA thinking that each year a number of children dies due to vaccination side effects. Preliminary results indicate that perceptions of vaccines in general, especially concerning the need for and the effectiveness, were the strongest predictors of vaccination intention in both AD and PA.

Conclusions:

Adolescents and their parents seemed well informed about meningococcal disease, but less about vaccinations. The belief that vaccines are needed and effective in preventing infectious diseases seems to be of more importance in vaccination decisions than other beliefs of disease and vaccination. Future communications need to address the identified misbeliefs and emphasize the need for and effectiveness of vaccines.

Key messages:

- MenACWY vaccination intentions are more dependent on beliefs about vaccines in general than on beliefs about meningococcal disease and the menACWY vaccination.
- The belief that vaccines are needed and effective in preventing infectious diseases is of major importance in menACWY vaccination decisions.

A systematic review of email-based reminder interventions to increase vaccine uptake

Carlo Signorelli

A Odone[1], *B Frascella*[1], *F Balzarini*[1], *A Oradini Alacreu*[1], *C Signorelli*[1]
[1]Vita-Salute San Raffaele University, Milan, Italy
Contact: signorellicarlo2307@gmail.com

Introduction:

Reminder and recall interventions have been proven to be effective in increasing vaccination coverage. Emails are a popular mean of communication, and their use as a reminder method has many potential benefits: low costs, timely delivery and no restriction of content. Nevertheless, there is limited evidence that compares the advantages of using emails for vaccination reminders to other methods, on which extensive literature is already present.

Methods:

We conducted a systematic review following the PRISMA guidelines to analyze evidence from peer-reviewed studies on the application of email-based interventions to immunization programs. We included any measure of vaccine uptake or immunization coverage, in any target population and settings.

Results:

We included 11 studies in the final analysis, of which 9 were RCTs, 1 was a controlled trial and 1 a before and after study. Most studies were conducted in the US. Six studies had data on the uptake of influenza vaccination, three on HPV series completion, 1 on PPSV23, and 1 on vaccines recommended for adolescents. In 4 studies email reminders proved to be more effective in increasing vaccination uptake than no reminders. Five studies didn't show advantages of using email reminders when compared to traditional methods (phone call, mail, paper card) and digital reminders (SMS, automated phone calls). In 1 study a significantly higher increase in uptake was achieved when combining emails with Interactive Voice Response phone calls. Finally, 2 studies compared different email models.

Conclusions:

In conclusion, this review outlined that not enough evidence is available regarding the use of email reminders to increase vaccination uptake. Our findings suggest that the choice of reminder method should depend on the population, and future studies should analyze its cost-effectiveness and convenience in respect to other methods, and aim at improving the content of emails to increase their efficacy as a reminder method.

Key messages:

- Based on our review of available studies, not enough evidence is available to prove the efficacy of email reminders to increase vaccine uptake.
- Additional evidence is needed to analyze cost-effectiveness of email reminders, convenience in respect to other methods, and to improve their content to increase their efficacy as a reminder method.

Information sources and attitudes of Polish migrants accepting or declining vaccination in Scotland

Dermot Gorman

DR Gorman[1]*, K Bielecki*[1]*, L Willocks*[1]*, K Pollock*[2]*, J Munshaw*[3]*, H Larson*[4]
[1]Public Health, NHS Lothian, Edinburgh, UK
[2]School of Health and Life Sciences, Glasgow Caledonian University, Glasgow, UK
[3]Health Improvement Team, NHS Health Scotland, Edinburgh, UK
[4]Vaccine Confidence Project, LSHTM, London, UK
Contact: dermot.gorman@nhslothian.scot.nhs.uk

Background:

Poland has the lowest EU vaccine confidence scores. The Polish are the largest migrant group in Scotland (91,000) with a high decline rate of nasal influenza vaccination. A new Polish language information leaflet in the 2018 school influenza programme saw consent form return increase but uptake remained low. We compare vaccination attitudes of accepting and declining parents.

Methods:

A questionnaire to 365 Polish parents after vaccination asked about the leaflet, vaccination, time in UK and included WHO Vaccine Hesitancy statements. Accepting and declining parents were compared.

Results:

128 (37%) responded - 42% of vaccinating and 39% declining parents. 90% were long term UK resident, 72% speak Polish at home. Previous experience had most influence in vaccination decision-making, with social media and personal contacts in Poland and Scotland also key. Decliners were more likely to cite social media than accepters. Concerns about new vaccines, side effects and 'currently uncommon conditions' are high in the Polish community and decliners hold more negative and scientifically 'incorrect' opinions. Parents know that Polish and UK immunisation schedules differ for influenza, a condition thought less serious in Poland than UK.

Conclusions:

Polish norms strongly influence this migrant group. Differences in how Polish migrants who accept or decline the vaccination respond to vaccine hesitancy statements plus knowing that Polish media and the Polish community shape their views can be used by health authorities to target health messages. It is important to be aware of immunisation status and vaccination beliefs of mobile migrant groups, such as the Polish, to prevent spread of vaccine preventable diseases in Europe. Linking vaccine hesitancy statement responses and behaviour can highlight national characteristics and particular concerns of vaccine hesitant parents. This information could be used to improve vaccine uptake rates among different ethnic minorities.

Key messages:

- Polish migrant children have low nasal influenza vaccine uptake. Vaccine hesitancy statements show decliners are particularly likely to distrust new vaccines and worry about vaccine side effects.
- Migrants access Polish social media and information and retain vaccination beliefs and norms post migration. Knowing this allows targeting of information campaigns to increase uptake.

Legionella control in a tertiary care hospital in Italy: adapting solutions to changing scenarios

Giovanni Noberasco

G Noberasco[1]*, A Battaglini*[1]*, F Grammatico*[1]*, M Zacconi*[1]*, A Battistini*[2]*, V Daturi*[2]*, D De Florentis*[2]*, A Borneto*[3]*, A Morando*[4]*, A Orsi*[1,2]
[1]Department of Health Sciences, University of Genoa, Genova, Italy
[2]Hygiene Unit, IRCCS Ospedale Policlinico San Martino, Genova, Italy
[3]Technical Services Unit, IRCCS Ospedale Policlinico San Martino, Genova, Italy
[4]Hospital Management Unit, IRCCS Ospedale Policlinico San Martino, Genova, Italy
Contact: noberasco.giovanni@gmail.com

Background:

Legionella contamination of hospital water distribution system still remains a critical issue in healthcare settings, despite the disputed relationship between environmental legionella and hospital-acquired legionellosis. We report the experience of our 1200-beds hospital, where a new water safety plan (WSP) has been applied since 2017, and the results obtained with the application of different methods to control Legionella water contamination, especially in critical areas.

Methods:

Policlinico San Martino is the referral tertiary acute-care university hospital in Liguria region, North-West Italy. It's made of 21 buildings of different dimensions, 7 of which host high risk patients, according to Italian Guidelines for legionellosis prevention and control. A sampling plan for Legionella detection was implemented in 2017, focusing on the water network critical points. Different secondary disinfection procedures were used, including systemic (chlorine dioxide, monochloramine), focal (point-of-use filtration) and short-term methods (hyperchlorination), the last in case of contamination higher than 10○4 CFU/l.

Results:

Respectively, during 2017 and 2018 a total of 201 and 119 hot water samples were collected, distributed among the 7 critical buildings of the hospital. Negative samples raised from 69.7% to 74.8%, while positive samples >10○3 CFU/l (recommended cut-off for acute disinfection according to Italian guidelines) lowered from 21.9% to 9.2% of total samples. Out of 55 positive samples, Legionella sg 3 accounted for 98.2% of the total.

Conclusions:

The new WSP determined a significant reduction of Legionella contamination of water distribution networks in our hospital critical buildings. The continuous surveillance of critical water system points provided evidence to elaborate an effective protocol for routine and extraordinary disinfection interventions, as result of a close collaboration between hospital hygiene unit and engineering and technical services.

Key messages:

- The implementation of an effective water safety plan and different disinfection procedures in hospital critical areas allow us to reduce and control the risk of hospital-acquired Legionella infection.
- Continuous surveillance cultures of drinking water to detect Legionella are necessary to adapt disinfection methods to local results.

RSV burden among hospitalized patients: 6-years surveillance of Liguria regional reference lab

Federico Grammatico

F Grammatico[1], F Butera[1], IG Iavarone[1], I Schenone[1], C Arcuri[1], G Barisione[1], G Guarona[1], L Sticchi[1,2], A Orsi[1,2], G Icardi[1,2]
[1]Department of Health Sciences, University of Genoa, Genova, Italy
[2]Hygiene Unit, IRCCS Ospedale Policlinico San Martino, Genova, Italy
Contact: federico.grammatico@edu.unige.it

Background:

Respiratory syncytial virus (RSV) represents one of the most common agent causing respiratory infections in infants and adults. It causes seasonal epidemics, with a peak prevalence in winter. RSV epidemiology and burden are still under-recognized, although it leads to complications and increased mortality in patients at risk, such as infants, pregnant women, the elderly and patients with chronic diseases.

Materials/Methods:

Data analyzed in this study were collected during the virological surveillance system activities at the Policlinico San Martino university hospital in Genoa, Italy. The regional reference laboratory receive swabs from all Liguria region, and detects the main circulating respiratory viruses by using molecular methods. The proportion rate of RSV (subtypes A and B) positive samples was determined in the period January 2013 - December 2018, stratifying data by gender, age and hospital units.

Results:

From January 2013 to December 2018, 14911 swabs were analyzed, 585 patients reported at least once RSV positive respiratory sample. The median age of RSV positive patients was 56 years (IQR 27-71), with a males: females ratio of 0.93: 1. The peak RSV infection period occurred mainly during first quarter, confirming the seasonal trend of the virus. Greatest proportion of RSV positive samples were received from hematology-oncology wards (45.2% of isolations) and medicine units (31.9%). From 2013 to 2018 an increase of swabs collection of 207% was observed. Neonatology and pediatrics resulted in the highest rate of positive swabs (above 30%), hemato-oncology departments collected 7932 swabs with 3,3 % resulted positive.

Conclusions:

A virological surveillance system able to detect the principal respiratory viruses circulating in adult population is a key element to better understand the RSV epidemiology and evaluate therapeutical strategies, in view of the availability of effective vaccines able to prevent RSV infection in the next future.

Key messages:

- RSV represents a leading cause of respiratory disease in hospitalized patients, especially in hematology-oncology, medicine and intensive care unit wards.
- Virological surveillance is a key element to better understand RSV epidemiology in all ages, in view of the availability of new effective vaccines.

Perioperative antibiotic prophylaxis: tools, results and reflections from a 6-year monitoring

Matteo d'Angelo

M d'Angelo[1], F Malacarne[1], G Perri[1], C Smaniotto[1], C Battistella[1], L Brunelli[1], A Madia[1], L Arnoldo[2], R Cocconi[3], S Brusaferro[4]
[1]Department of Medicine, University of Udine, Udine, Italy
[2]Accreditation, Clinical Risk Management and Performance Asse, Udine Healthcare and University Integrated Trust, Udine, Italy
[3]Santa Maria della Misericordia Academic Hospital, Udine Healthcare and University Integrated Trust, Udine, Italy
[4]Department of Medicine, Udine Healthcare and University Integrated Trust, Udine, Italy
Contact: matteo.dangelo@uniud.it

Background:

Perioperative antimicrobial prophylaxis is a key practice to prevent surgical site infection. The Udine Healthcare and University Integrated Trust has defined its features in a specific procedure, available on the hospital Intranet. Compliance with the procedure has been monitored on a semi-annual basis.

Methods:

Between July 2013 and December 2018 15 clinical records per semester for each one of the 16 surgical units were randomly extracted, including ordinary admissions with clean or clean/contaminated surgery. Compliance with the procedure was monitored for all the items considered: drug, dosage, timing of administration, redosing and duration of prophylaxis. A first comparison analysis both between semesters and for longer time frames was performed with the chi-square test; to evaluate the presence of a linear trend all over time (in semestres), the Pearson linear correlation coefficient was calculated; in case of correlation, a simple two-variable linear regression analysis was performed. Statistical significance was assessed for $p < 0.05$.

Results:

A sample of 2775 records was evaluated. Focusing on the first and last semester of monitoring, overall compliance increased in 9 of the 16 units, although there is a drop, when extending the analysis to the whole sample (72% vs 70.8%) with no statistical significance. Otherwise a statistically significant difference is recorded between the first and the last two years of analysis ($p < 0.007$), with an increase of overall compliance from 64.2% (2013-2014) to 69.7% (2017-2018). Finally a strong and significant negative correlation between time and overall compliance to redosing emerges ($r = -0.79$; $p = 0.004$).

Conclusions:

Compliance with hospital procedure has substantially improved over time reaching a stable performance value. However the linear regression analysis highlights the need to implement new intervention strategies in order to increase overall compliance to redosing.

Key messages:

- Overall compliance with hospital procedure has improved over time.
- Results highlight the need to implement new intervention strategies.

Prevalence of measles IgG antibodies among immigrant workers in South Korea

Yu-Mi Kim

YM Kim[1], BG Kim[1], YS Hong[1]
[1]Department of Preventive Medicine, Dong-A University College of Medicine, Busan, South Korea
Contact: kimyumi@dau.ac.kr

Background:

After the national vaccination for measles was introduced in 1985, the measles has been controlled in South Korea despite the epidemic in 2000-2001. Current cases in Korea were assumed to be transmitted from outside the country. Because the dynamics and social changes of the population has emerged as important factors in the measles epidemic, this study aimed to assess the prevalence of measles IgG antibodies among immigrant workers.

Methods:

The cross sectional seroprevalence survey was conducted in Gyeongsangnamdo province, Korea. Because the representative sampling frame could not be possible, the voluntary foreign workers who have agreed informed consents with a translated format into the native language, participated in this study. IgG antibodies of measles was examined by ELISA using the automation equipment (BEP III- ELISA). This study obtained the approval of Dong-A University Clinical Research Ethics Review Committee.

Results:

364 people of foreign workers participated in the study. Regional distribution for study participants was composed of 30 people in Vietnam (16.5%), Uzbekistan 71 people (19.5%), Thailand 70 people (19.2%), China 60 people (16.5%), Philippines 36 people (9.9%), and Indonesia 32 people (8.8%). The average age was 33.0 ± 6.9 years old and 86.5% of the total was men. High school or higher education accounted for 74%. 93.7% showed positivity (95% CI: 95.7-98.9%) for measles IgG antibody and 3.6% showed equivocal.

Conclusions:

The measles seropositivity among immigrant workers in Korea was considered to be at the recommended level.

Key messages:

- The measles seropositivity among immigrant workers in Korea was considered to be at the recommended level.
- International cooperation is needed to prevent global measles epidemic.

Determinants of influenza vaccination uptake among Polish school teachers

Maria Ganczak

M Ganczak[1], D Biesiada[1,2], A Molas-Biesiada[1,2], K Topczewska[1], M Drozd-Dąbrowska[1]
[1]Department of Epidemiology and Management, Pomeranian Medical University, Szczecin, Poland
[2]Primary Care Practice, Bierznik, Poland
Contact: ganczak2@wp.pl

Background:

School settings place teachers at risk for influenza infection. Polish National Immunization Program recommends influenza vaccination (IV) for this occupational group. The study objective was to assess teachers' knowledge and attitudes regarding IV, to determine 2018/2019 uptake and factors influencing the IV receipt; this has never been performed before in Central/Eastern Europe.

Methods:

Between March-April 2019 teachers from 5 randomly selected primary schools (2 urban, 3 suburban) in West Pomerania, Poland, were surveyed with the use of the self-administered, anonymous questionnaire.

Results:

Response rate was 50.1%. Among 102 respondents (68.6% females, mean age 45.7 years, mean length of practice 20.3 years), 31.4% were chronically ill. Only 4.9% reported getting the 2018/2019 IV, 8.8% were willing to be vaccinated in the next season. Of the respondents getting the 2018/2019 IV, only one also re-ported getting the 2017/2018 vaccine. The most common source of information about the IV were: family doctor (55.9%) and TV (68.6%). Beliefs that the IV was not effective (40.2%%) and concerns about the side effects (19.6%) were the most common reasons for not getting it. Only 44.1% of respondents believed teachers have heightened risk of contracting influenza. Regarding preventive methods, 83.3% teachers pointed at social distancing, 65.7% - at frequent handwash-ing, 65.7% - at vaccination; 38.2% believed that drinking tea with lemon could prevent influenza. More than a third of teachers (38.4%) thought influenza infection is always symptomatic. Older age was the only factor independently associated with IV receipt ($p < 0.05$).

Conclusions:

Influenza vaccination coverage among Polish primary school teachers is disturbingly low. Future education strategies encouraging teachers to immunize themselves against influenza should tackle misconceptions about the IV and increase awareness. Interventions related to maximizing IV uptake should focus especially on younger teachers.

Key messages:

- This preliminary study showed that influenza vaccination coverage among Polish primary school teachers urgently needs improvement.
- Teachers should better understand the importance of influenza vaccination as a significant preventive measure and realize their role in infection prevention and transmission at the school setting.

Health professionals as parents are not immune to vaccine hesitancy – an Italian national survey

Sofia Zanovello

M Fonzo[1], C Bertoncello[1], S Cocchio[1], S Zanovello[1], SE Bennici[1], T Baldovin[1], A Buja[1], G Napoletano[2], F Russo[2], V Baldo[1]
[1]Hygiene and Public Health Unit, DCTV, University of Padova, Padova, Italy
[2]Servizio Promozione e Sviluppo Igiene e Sanità Pubblica, Direzione Prevenzione, Regione Veneto, Venezia, Italy
Contact: sofia.zanovello@studenti.unipd.it

Vaccine hesitancy is a growing concern in many European countries, including Italy, as instanced by alarming results from Eurobarometer 488 dated April 2019. In the view of the current magnitude of the phenomenon, our aim was to investigate its determinants among parents, with a specific view on those working as health professional.

In 2017, parents of children aged 3-84 months were recruited online. Based on self-reported vaccine status and timeliness of vaccinations, parents were classified as pro-, hesitant, or anti-vaccine. The association between baseline characteristics and hesitancy was investigated with logistic regression adjusting for child's and parents' age, prematurity, presence of older children, previous vaccine adverse reaction in the child at issue, parents' nationality, education and employment status, health profession of at least one parent, single parenting, vegetarian lifestyle and perceived economic security.

A total of 3,865 questionnaires were collected (64% pro-, 32% hesitant, 4% anti-vaccine). Families with at least one health professional as parent were 20% of the sample.

Vegetarian lifestyle (aOR 3.0; 95%CI 2.20-4.08), unsatisfactory (aOR 1.67 95%CI 1.08-2.58) and partially satisfactory perceived economic security (aOR 1.40; 95%CI 1.09-1.78) and previous vaccine adverse reactions (aOR 1.25; 95%CI 1.05-1.48) were associated with vaccine hesitancy, while having older children resulted as a protective factor (aOR 0.82; 95%CI 0.69-0.98). No significant association was found with other abovementioned variables, including parent employed as health professional (aOR 0.99; 95%CI 0.81-1.22).

Vaccine hesitancy seems to be part of a lifestyle choice and, to a smaller extent, associated with previous vaccine adverse reactions and lower socioeconomic status. Interestingly, parents' level of education and employment in healthcare do not affect vaccine acceptance. The latter poses a challenge, given their crucial role in promoting vaccination.

Key messages:

- Hesitancy is associated with lifestyle choices, experience of adverse reactions and socioeconomic status, while education and employment as health professional seem not to be relevant.
- Whether they are health professionals or not, parents' attitude towards their child's vaccinations is the same.

Understanding the complexities of HIV risk among sexual minority men in a global context

Kristefer Stojanovski

K Stojanovski[1], *EJ King*[1]
[1]Health Behavior & Health Education, University of Michigan, Ann Arbor, USA
Contact: kstojan@umich.edu

Background:

Complex systems theory recognizes the intricacy of health issues and inequities, which permits the study of interrelationships across multiple levels of the socioecological model. We interrogated the research to identify upstream and downstream factors, their intersections, and recursive processes to develop a visualization of HIV risk among sexual minority men.

Methods:

Using global HIV literature drawn from diverse disciplines and geographies, we elucidated HIV risk factors through a complex systems theory approach. We used thematic analysis to categorize HIV risk factors into different levels of the socioecological model, such as policies, community risk factors, individual behaviors, etc. We also identified the relationships between these risk factors to assess how they shaped HIV risk. The analyses were used to inform the connections between the various factors that lead to HIV risk in order to develop a visualization of the complex system, for which Stella Architecture was used.

Results:

The thematic analysis of the literature and complex systems visualization portrays that HIV risk arises from a complex interplay of recursive and reinforcing factors ranging from policies, community factors, healthcare systems, and interpersonal relationships leading to manipulations in individual-level behaviors that put sexual minority men at risk for HIV. This visual representation indicates that HIV risk cannot simply be thought of as an individual-level factor nor simply related to sexual behaviors. Rather, HIV risk arises from upstream societal forces such as stigma, poor mental health, and health systems that relate to a multitude of downstream factors that socially pattern sexual minority men's HIV risk.

Conclusions:

The risk of HIV among sexual minority men stems from numerous intersecting factors across multiple levels of the socioecological model indicating the need to improve structural- and community-oriented approaches to address HIV.

Key messages:

- HIV risk arises from multiple social determinants.
- HIV preventions need to encompass multi-level interventions to fully address HIV risk.

Influenza vaccination: a multi-modal approach to increase compliance in an italian teaching hospital

Francesca Malacarne

D Celotto[1], *F Malacarne*[1], *C Battistella*[1], *FG Bucci*[1], *F Antinolfi*[1], *L Brunelli*[1], *R Cocconi*[2], *D Tignonsini*[2], *A Faruzzo*[2], *S Brusaferro*[1,2]
[1]Department of Medicine, University of Udine, Udine, Italy
[2]Udine Healthcare and University Integrated Trust, Udine, Italy
Contact: francesca.malacarne@uniud.it

Issue:

Influenza vaccination of Healthcare workers (HCW) has a key role in avoiding flu transmission among patients and HCWs and is annually recommended by health authorities. Despite the 75% target identified by WHO, coverage is still inadequate in many European countries.

Description of the problem:

The Infection Control Team and Public Health Residents of a University Hospital annually cooperate to actively offer flu shots directly in the Units, but in 2017-18 campaign only 12,1% of HCWs took advantage of the service. From July to December 2018 a composite intervention was performed to increase immunization rates. In each Unit a medical doctor and a nurse (midwife for the Obstetrics unit) were identified as Link Professionals (LPs).Two educational meetings with Infectious Diseases and Public Health experts were organized for LPs to deal with their hesitancies and to engage them for the vaccination promotion among colleagues.The calendar (2/week ambulatory + 16 in-ward appointments), tailored to maximise the HCW accessibility, was sent to medical consultants and head of departments, to all physicians, and to head nurses for dissemination. Promotional posters and videos were displayed across the hospital.

Results:

Educational meetings were attended by 130 LPs. A total of 772/3420 HCW took advantage of the 2018-19 active campaign (22,6%), with a significant increase from the previous year (+10,4%; 95%CI 8,7-12,2; $p < 0{,}001$). The immunization rates raised in all HCWs categories: 279/660 doctors (it was 167/660 in 2017-18; +17.0%; 95%CI 11,9-21.9; $p < 0{,}001$); 303/1615 nurses (150/1615 in 2017-18; +9.5%; 95%CI 7.1-11-9; $p < 0{,}001$); 13/43 midwives (2/43 in 2017-18; +25,6%; 95%CI 9.7-40.8; $p = 0{,}002$).

Lessons:

Despite the significant increase,further efforts are necessary to reach the WHO target rate. All HCWs categories were positively affected by the multi-modal intervention. LPs seem to play an important role in promoting vaccination among colleagues, in a peer-to-peer trust relationship.

Key messages:

- Influenza vaccination rates needs to be increased in healthcare workers for their protection and for patient safety.
- A well-structured multi-modal intervention programme involving prepared HCW promoters into wards is essential to increase compliance.

Vaccination, Autonomy, Complexity, Solidarity - Ethical analyses of a German policy discourse

Peter Schröder-Bäck

P Schröder-Bäck[1], *F Gille*[2], *C Brall*[2], *K Martakis*[1,3,4], *J Kuhn*[5]
[1]Department of International Health, Maastricht University, International Health, Maastricht, Netherlands
[2]Health Ethics and Policy Lab, D-HEST, ETH Zürich, Zürich, Switzerland
[3]Klinik und Poliklinik für Kinder- und Jugendmedizin, Uniklinik Köln, Köln, Germany
[4]Department of Child Neurology, Justus-Liebig University Gießen, Gießen, Germany
[5]Abteilung Gesundheit, Landesamt für Gesundheit und Lebensmittelsicherheit, Oberschleißheim, Germany
Contact: peter.schroder@maastrichtuniversity.nl

Background:

Currently, measles immunization is high on the agenda of academic and public discourses - on both sides of the Atlantic. In Germany, the discussion of mandatory (measles) immunization was intensively publicly discussed in Spring 2019. Many stakeholders, including federal politicians, plea for mandatory measles immunization. In our paper we analyse the discourse from an ethical point of view.

Methods:

Statements and arguments from German stakeholders in the public debate in 2019 are analysed (among them statements of the federal minister of health, the German Medical Association, NGOs and the National Ethics Council). A vaccination ethics framework and a public trust framework are applied in the analysis.

Results:

Politicians and other public stakeholders debate (measles) immunization and increasingly demand mandatory (measles) vaccination. However, frequently it is unclear which vaccinations or immunization programmes they refer to. They often do ignore the epidemiological situation of immunization rates in Germany, regional differences, relevant target groups and implementation mechanisms, including potential sanctions. This way they simplify the complex problem and offer (populist) simplistic solutions. Normative arguments of stakeholders repeatedly use conceptions of 'autonomy' and 'harm'; but sometimes also 'solidarity' is mentioned.

Conclusions:

The call for mandatory measles immunization of school and kindergarten children is offering no adequate and sufficient solution to the problem of elimination of measles. Nevertheless, it contributes to reducing infection risks for the children in care and schooling facilities. Rather, the problem has to be understood in its complexity before discussing the ethical challenges and making effective policy recommendations. When discussing ways to increase immunization rates, ethical values like public trust and solidarity have to be in the foreground - not (only) the debate of autonomy and its restriction.

Key messages:

- In German policy discourses 2019, the discussion of "mandatory (measles) vaccination" often shows inaccuracies regarding definitions and facts. These have to be clarified before ethical analysis.
- Ethical issues regarding the voluntariness of measles vaccination relate also to the ethical concepts of solidarity and public trust and not only to autonomy.

Pediatric vaccination appointment scheduling: experience from an Italian clinic

Claudia Cuccaro

F Toscano[1], C Cuccaro[1], E Ceriale[3], A Mercone[3], S Rossi[2], N Nante[2], G Messina[2], A Bagnoli[3]
[1]Post Graduate School of Public Health, Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[2]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[3]Public Hygiene and Nutrition, USL Tuscany South East, Siena, Italy
Contact: claudia.cuccaro@student.unisi.it

Issue/problem:

Since 2012 pediatric vaccination coverages in Italy have been decreasing. Negative trends have been recorded especially for hexavalent and MMR vaccines. In mid-2017 the Italian government passed an act making ten vaccines compulsory. Most recent data show the act is working, however other aspects of the process should be improved.

Description of the problem:

Parents are invited to bring their children to the clinic through letters or telephone calls. Vaccination appointments are scheduled during weekdays, either in the morning, the afternoon, or both. Each session is carried out by a physician and a nurse, with a new patient scheduled every ten minutes. Appointments and vaccinations are registered on the vaccine-specific electronic health record (SISPC).

Results:

In March 2019, the vaccination clinic worked 21 days for a total of 29 sessions. 823 appointments were available, 797 of them (96.8%) had a patient scheduled before the session started. 547 (68.6%) attended the vaccination appointment, 98.4% of them were vaccinated (538, 67.5% of the total patients scheduled). Among those who did not attend the scheduled appointment, only 108 (43.2%) agreed to reschedule. Eventually, only 58.3% of these patients attended the rescheduled appointment. No statistically significant differences among those who attended and those who did not attend the appointment were found among the variables retrieved from SISPC: day, time, vaccination planned (type, and if mandatory or not), sex, age.

Lessons:

A third of available vaccination appointments in our clinic were lost. Despite the ease through which patients can reschedule an appointment, many choose not to and left their appointments unattended. Although missing a vaccination appointment can be appropriate - e.g. when the child is sick - and great effort should be put to achieve the goal of improving coverages, policymakers should also consider provisions to discourage such behaviors for a better use of resources.

Key messages:

- A third of available vaccination appointments in our clinic were lost in a month.
- Keeping in mind the goal of improving coverages, policymakers should aim for the best possible use of resources.

A model of Carbapenemase-Producing Enterobacteriaceae spreading in the French hospitals network

Pascal Crépey

J Roux[1], C Massonnaud[1], P Crépey[1]
[1]Reperes – EA 7449, Univ Rennes, EHESP, Rennes, France
Contact: pascal.crepey@ehesp.fr

Background:

Carbapenemase-Producing Enterobacteriaceae (CPE) are spreading at an alarming rate and threaten health systems and patient safety worldwide. In France, their transmission is driven by importation of international cases and inter-regional dissemination due to patients' transfers between hospitals. This study aims at defining a mathematical model reproducing CPE transmission on the French network of hospitals.

Methods:

CPE spreading is modeled using a stochastic susceptible-colonized-infected (SCI) hospital-based model. It takes into account both CPE dissemination through patient transfers, and importations either from foreign countries or in-town transmission. The patient transfer network was reconstructed using data from the French hospital discharge database (PMSI) over the years 2014-2017. Epidemiological parameters were estimated from surveillance data of CPE episodes from August 2010 to November 2016 from the French national Healthcare-Associated Infections Early Warning and Response System.

Results:

Our epidemiological model replicates the number of CPE hospital outbreaks occurring in France on a network of 2,433 hospitals. It allows to estimate the number of unobserved hospitals' colonization and differentiate outbreaks due to foreign importation from outbreaks due to patient transfers. Finally, the model can be used to benchmark control strategies based on patient redirections, or targeted screening.

Conclusions:

This study is the first to simulate CPE spread in France using real-life patient transfers data. Our mathematical model may further help public health authorities in the definition and evaluation of new control strategies of CPE transmission based on patient flows between hospitals.

Key messages:

- The mathematical model take into account CPE spreading through hospital transfers and importations from origins using real-life data.
- Our stochastic susceptible-colonized-infected (SCI) hospital-based model reproduces CPE spread in France and further help in evaluating control strategies of CPE transmission.

Local Tuberculosis Georeference: a tool to define BCG vaccination in high-incidence area in Portugal

Andreia Leite

E Freire Rodrigues[1], A Leite[1,2], M Cabral[1], G Duarte[1], AP Marques[1], E Cale[1], AC Silva[1]
[1]Public Health Unit, Primary Health Care Cluster Amadora, Amadora, Portugal
[2]Public Health Research Centre, National School of Public Health, Nova University Lisbon, Lisbon, Portugal
Contact: andreiaheitorleite@gmail.com

Issue:

Tuberculosis (TB) incidence in Portugal is $< 20/100000$ people, with high-incidence municipalities in urban areas such as Amadora. In 2016, the national vaccination programme moved the BCG vaccine from universal to restricted risk groups. Amadora, due to the higher-incidence area, maintained a universal vaccination policy. Recently, it was hypothesized that vaccination could be applied to specific parishes even in high incidence counties.

Description:

We aimed to identify specific geographic areas with higher risk of TB to help redefine the local BCG vaccination policy. We proposed to georeference active TB cases between 2015 and 2017, in Amadora, to then assess the incidence per parish and statistical section. We also aimed at identifying geo-clusters and density of cases.

Methods:

(1) notified TB cases from 1 January of 2015 to 31 December 2017 were extracted from TB surveillance system; (2) cases of latent TB infection (LTBI), cases out of Amadora's bounds and without national ID were excluded; (3) ArcGis®Online and associated maps were used to provide populational estimates; (4) cumulative incidence was calculated per year and averaged for the 3-year period; (5) Clusters were determined using distance and simple density of cases was calculated using Kernel algorithm.

Results:

Considering the 6 parishes of Amadora, the 3-year cumulative incidence varied from 19.58 to 38.3 per 100000 hab. The highest incidence was found on the parish with the best socio-economic profile. 14 geo-clusters were mapped; 3 matched known deprived neighborhoods. Overall density was higher in these neighborhoods.

Lessons:

With this approach we found that deprived neighborhoods had higher levels of case density, but 3-year cumulative incidence was higher on the parish considered to have low occurrence of TB. As such, and due to the intense population flows in Amadora, the local public health unit recommended the persistence of BCG vaccination to all residents of the municipality.

Key messages:

- Georeferecing supported our recommendation to mantain a universal BCG vaccination policy.
- Georeferencing associated to surveillance systems is highly useful to ensure evidence based public health practices, even at the local level.

Late presentation of chronic hepatitis B virus in Spain: a country with access to therapy

Jeffrey Lazarus

C Picchio[1], E Roel[1], M Buti[2,10], S Lens[3,4,10], RJ Andrade[5], J Crespo[6], JL Calleja[7], MA Simon[8,9], JV Lazarus[1]

[9]Instituto de Investigación Sanitario Aragón, (IIAS Aragón), Zaragoza, Spain
[10]CIBER Hepatis and Digestive Diseases (CIBERehd), Instituto Carlos III, Madrid, Spain
Contact: jeffrey.lazarus@isglobal.org

Background and aims:

Chronic infection with hepatitis B virus (HBV) can progress to liver cirrhosis and lead to complications such as decompensated liver disease, hepatocellular carcinoma and liver-related death. Antiviral agents against HBV are very effective in suppressing viremia and greatly reduce the risk of complications if treatment is initiated before the onset of advanced liver disease. The aim of this study is to assess the prevalence of late presentation in leading hospitals across Spain.

Methods:

Retrospective cohort study of patients seeking first time care with a liver specialist at six tertiary Spanish hospitals, with 2018 data. Late presentation (LP) included advanced liver disease (ALD) defined by significant fibrosis ($\geq$ F3 assessed by either APRI score > 1.5, FIB-4 > 3.2, transient elastography (FibroScan) > 9.5 kPa or biopsy $\geq$ METAVIR stage F3) with no previous antiviral treatment and late-stage liver disease (LSLD) was defined by the presence of decompensated cirrhosis and/or hepatocellular carcinoma. Prevalence of ALD and LSLD at first consultation, demographics, and associated risk factors were analysed.

Results:

203 patients chronically infected with HBV were included. Advanced liver disease was detected in 14.8% and late stage liver disease was observed in 6.1% of cases. 57.1% of the cases were male. The majority of those with HBV were non-Spanish (53.7%). The median age was 47 and the median of years from diagnosis to specialist care was 1 (IQR 7). 58.6% of patients were referred from primary care and 3.7% cases had hepatocellular carcinoma upon presentation for care.

Conclusions:

Late presentation with HBV is common in Spain, particularly for the foreign-born population, despite full access to antiviral therapy for HBV in the country. In order to rectify this health systems failure, improve outcomes and reach the viral hepatitis elimination goal adopted by WHO in 2016, strategies to reduce late presentation to care are essential.

Key messages:

- Early diagnosis of HBV is needed in order to rectify the health systems failure of late presentation to care.
- Interventions targeting foreign-born populations should be implemented to reduce late presentation to HBV care and treatment.

DQ Learning from practice

Improving the operational skills of the health personnel working in the emergency departments

Roberta Arnone

R Arnone[1], G Romano[1], J Skinner[2], S Watt[3], C Poenicke[4], D Hoestergard[5], G Chiaramonte[6]
[1]CEFPAS, Caltanissetta, Italy
[2]Edinburgh University of Medicine, Edinburgh, UK
[3]Napier University, Edinburgh, UK
[4]Dresden University of technology, Dresden, Germany
[5]DIMS, Copenhagen, Denmark
[6]ISMETT, Palermo, Italy
Contact: arnone@cefpas.it

In December 2013 the European Commission approved the project promoted by CEFPAS, The Centre for Training and Research in Public Health within the programme PROGRESS, "Improving the operational skills of health personnel working in the emergency departments. A useful tool to give concrete answers to EU policies on patients' safety and to create new working opportunities".

This project aimed to combine the need to find innovative solutions in the field of healthcare with the objective of increasing the safety of patients in emergency departments, while also covering the need to promote worker mobility within the European Union. The key tool for implementing this goal is the exchange of experience and best practices.

The project partners included: the Edinburgh University of Medicine, the Napier University (again in Edinburgh), the

Dresden University of Technology, the Herlev Hospital (in Copenhagen) through the DIMS or the Danish Institute for Medical Simulation at the University of Copenhagen, as well as ISMETT and CREAM (the Research Centre of the University of Medicine) in Palermo.

Every partner, during the planning, has provided the know how developed in the area of emergency. Specifically it has been analyzed the possibility to compare and visit the simulation Centres of Edinburgh, Dresden and Palermo, and to study the use, in each country, of innovative methodology during the training of the health personnel.

The partner, during the planning of the project, studied also how to help people to find easier jobs opportunities in the health sector (so they thought to create a specific data base of the emergency departments operating in Italy, Scotland and Germany where to find a job or a chance for an internship).

The project has lasted for one year and has provided research activities and the exchange of experience and best practices.

Key messages:

- There is a huge difference regarding the way in which the emergency system is organized within single countries around Europe.
- Comparing high-level organisations we have benefited in terms of ideas, projects and potential objectives to be set in order to improve our work and to improve results for patients.

Feedback on the transition to routine use of Connexin, a tool to improve city-hospital cooperation

Anne Duburcq

V Durocher[1], A Duburcq[2], R Pamart[2]
[1]ValDConseil, Boulogne-Billancourt, France
[2]Public health department, Cemka, Bourg-la-Reine, France
Contact: anne.duburcq@cemka.fr

Issue:

The French national health strategy ''Ma Santé 2022'' underlines the need to decompartmentalize the organization of care through city-hospital cooperation. The Connexin® platform aims, as part of treatments prescribed in hospitals and delivered in community, to identify all health professionals around the patient, and ensure they communicate and coordinate with each other to improve the coherence and relevance of care within the pathway.

Description of the problem:

A pilot phase of deployment of the tool was conducted in two regions to measure the organizational and clinical impact of its use. This evaluation was based on qualitative interviews with the various stakeholders (local pharmacists, hospital teams, institutional partners, etc.). The objective was to assess the adoption and transition phases while identifying its effects and added value for health professionals using it.

Results:

Adherence was important: many pharmacists registered, reflection on the service organization in hospital teams. Despite some access problems (codes lost, dual authentication), professionals believe Connexin® facilitates communication between primary care and hospital actors. However, transition was difficult in several hospitals (lack of support from management mainly), insufficient use by pharmacists (hampered by the new missions entrusted to them by law). Support closest to professionals in the tool implementation thus seems crucial to ensure transition to routine use.

Lessons:

Connexin® is a secure, intuitive platform adapted to health professionals' needs for cooperation. Mobilization of the various actors around the platform proves the interest for and the relevance of such a tool to optimize the efficiency of care. However, the organizational impact, no matter how small, is a barrier to the transition to routine use, a finding shared for many tools.

Key messages:

- While the platform was designed by primary, hospital and institutional health professionals, the study points out the need to set up a project governance and appropriate support during implementation.
- Any organization impact is an obstacle to the evolution of practices.

How to build the partnership between researchers and field actors?

Christine Ferron

C Ferron[1,2,3], R Joanny[4], E Le Grand[2], M Porcherie[2], S Rohou[5]
[1]Fédération Nationale d'éducation et de Promotion de la Santé, Saint-Denis, France
[2]Ecole des Hautes Etudes en Santé Publique, Rennes, France
[3]Société Française de Santé Publique, Laxou, France
[4]Instance Régionale d'éducation et de Promotion de la Santé de Bretagne, Rennes, France
[5]Mutualité Française Bretagne, Rennes, France
Contact: christine.ferron@fnes.fr

In health promotion, the partnership between researchers and practitioners (field actors) is necessary for multiple reasons: to build intervention research together, to share our knowledge and experience, to produce new knowledge and experience, and to improve the quality of interventions, decisions... and research.

In order to build this partnership and to achieve these goals, two dimensions were explored during several mixed workshops (researchers and field actors) organized in Brittany (France): their reciprocal perceptions, and what they can mutually bring to each other.

During the first workshop, a facilitation technique called ''the figure,'' (which health educators use when they need to underscore the perceptions of a group of professionals about a specific population) shed light on mutual misconceptions and helped rectify them. During the following workshops, both groups identified their common assets, resources, difficulties and stakes. They also highlighted what they could bring to each other.

Indeed, the relationship between researchers and field actors is usually considered in terms of the contributions of research to actions. However, field actors are more than simple ''users'' of a knowledge produced by others, they are also ''producers' of knowledge. They can contribute to define research questions, issues, hypotheses (with a social twist...); challenge the relevance and feasibility of research; promote the link and the understanding between the two separate worlds of practice and research; encourage the making of certain research protocols; facilitate experimentation; check the validity of the research projects in terms of social usefulness; make research more visible to field professionals and policy makers; and support knowledge transfer and exchange.

The ways in which the partnership between researchers and health promotion actors actually enrich both categories of professionals, are detailed in this presentation.

Key messages:

- Reciprocal representations of researchers and practitioners in the field of health promotion must be highlighted to lay the foundations of their partnership.
- In health promotion, knowledge transfer must be understood as an exchange between researchers and field actors, the latter being experts in their domain of intervention and producers of knowledge.

Show your rare, handle with care: a knowledge brokers network to handle rare disease patients

Fabiana Rubba

F Rubba[1], R Alfano[1], D Schiavone[1], MS Scamardo[1], D Landolfo[1], O Barbieri[1], I Carannante[1], G D'Onofrio[1], A Guida[2], M Triassi[1]
[1]AOU Federico II, Naples, Italy
[2]Health Department, Campania Region, Naples, Italy
Contact: fabiana.rubba@unina.it

Background:

In Rare diseases patients. difficult in diagnosis can produce inappropriate pathways of care. A correct diagnosis took almost 5 years in Europe and 7.3-7.6 y in US. The directive 2011/24/EU provides a legal regulatory asset for the European Reference Networks (ERNs). ERNs are designed to connect health care providers and centers of expertise for gaining appropriate pathways of high-quality care and to support sponsorship in order to make healthcare closer to the patients. Federico II University actually has 9 confirmed ERNs.

Methods:

We connected the patient related activities inside the ERNs and we planned a project-based network that creates harmonization of diagnostic tools and widespread diffusion of screening activity able to drive diagnostic enrichment. The Hospital Chief Office together with the Public Health Department acts as ''Knowledge brokers'' (KB) defined as connectors who may crisscross the hierarchical boundaries. We scheduled interventions into the ERNs and future improvements. Interventions areas have been represented in a conceptual map.

Results:

Brokers into the network are attended to allow better merged innovation rate and sharing data. Improvements could be directed toward: 1) sharing data and communication, 2) diagnostic enrichment 3) hospital services networking into the path. Including this model in the regional pathways may build a common platform to support appropriate care in disease-endemic regions.

The designed model finally aimed at define how humanization and networking of care can be measured as gain in efficiency along the overall path.

Conclusions:

Network potential may overload a simply specific hub focused approach. The ''criss cross'' knowledge brokering (could be a strategy able to support clinical and diagnostic activities. To proceed over, in orphan disease handling, we may progress from approaches centered on florid cases toward a balanced screening design, able to guarantee a diagnostic enrichment for a rare condition.

Key messages:

- Implicit and formal Networking cam help rare disease handling.
- Sharing data and diagnostic enrichment are the main issues.

Recording educational information in medical record: the experience of a Rehabilitation Hospital

Enrico Scarpis

E Scarpis[1], M Poletto[1], J Guardini[2], C Londero[2], MR Maestra[2], GP Tea[2], A Zampa[2], L Lattuada[2], L Castriotta[2], S Brusaferro[1,2]
[1]Department of Medicine, University of Udine, Udine, Italy
[2]Udine Healthcare and University Integrated Trust, Udine, Italy
Contact: scarpis.enrico@gmail.com

Issue/Problem:

Healthcare organizations have the responsibility to provide education to patients and families so that they have the knowledge to participate in the care process and make decisions. Rehabilitative organizations, on account of the long hospitalization period and the specific care plans, have to organize education resources in the most effective manner, ensuring the registration of what has been done in the medical record (MR).

Description of the problem:

During the accreditation process, IMFR (Medical and Physical Rehabilitation Institute - an hospital part of the Udine Healthcare Trust) launched a MR-quality program. A dedicated team of 3 doctors, 4 nurses and 4 therapists changed the way in recording educational information in MR, introducing in April 2018 a specific, independent form, part of the MR, where documenting the achievement of two educational phases: assessment and delivery. The aim of this project is to determine if the introduction of this specific educational form and its sharing process, included in the wider MR-quality program, would improve the recording behavior. Twenty MRs were quarterly analyzed from December 2017 to December 2018, assessing educational forms completeness. Significance ($p < 0.01$) was assessed by Cochran-Armitage test for trends.

Results:

The recording behavior improved significantly from 53% (21/40; Dec-17) to 88% (30/34) in June 2018, after the introduction of the specific education form and remained high also in Sept.2018 (90%, 34/38) and in Dec.2018 (82%, 31/38), with an overall trend of + 29%.

Lessons:

Sharing elements in the creation of the specific educational form with a multidisciplinary approach, within a wider MR-quality program, allows to improve the recording behavior of educational information in it. Hopefully this method would help healthcare professionals and organizations to ensure the education needed to patients and families.

Key messages:

- A multidisciplinary approach is a good model to deal with specific aspects of quality programs.
- A specific form, part of the MR, allows to improve behavior in recording educational information.

The development of an evaluation framework on community impact of CSL in the Netherlands

Marijke Visser

MW Visser[1], MBM Zweekhorst[1]
[1]Athena Institute, VU University Amsterdam, Amsterdam, Netherlands
Contact: m.w.visser@vu.nl

Background:

Community Service Learning (CSL) is taking ground in higher education. In CSL, students use their academic skills to address society issues in close collaboration with the community. Reciprocity between community and university is conditional for meaningful CSL. Currently, much attention lies on student skills and competency development. There is less focus on the impact of CSL on the community. To move towards higher impact, we developed an evaluation framework on community impact in CSL.

Methods:

We conducted a systematic literature review to identify criteria on community impact in CSL. The identified criteria were structured in the CIPP framework (Context, Input, Process and Product). Next, we validated the concept framework in 5 CSL activities of the VU University Amsterdam, using participant observation, interviews, questionnaires and document analysis (multi perspective).

Results:

The underlying rationale of the framework is that (supported) community involvement - from start till finish - contributes to higher community impact in CSL. Context criteria relate to motivation and expectations of all stakeholders. Input criteria include available human, financial and material resources. In Process, there is attention to the way CSL is shaped with the community. Product criteria include how community perspectives are integrated in outcomes, and how outcomes are perceived and implemented by the community. The validation of the framework did not result in major changes, but contributed to specification of individual criteria.

Conclusions:

The development and validation of the framework is an iterative and cyclic process, open for further validation and improvement. To realize most impact learning and reflection processes with all stakeholders are essential. The framework should not only be used to asses community impact, but also to design and implement CSL in order to realize high community impact.

Key messages:

- A monitoring and evaluation framework of community impact provides groundwork for high impact CSL activities.

- Meaningful community involvement will result in higher impact CSL activities.

How to implement a successful smoking cessation intervention for adolescents?

Amandine Vallata

A Vallata[1], *F Alla*[2]
[1]EA 4360 APEMAC, University of Lorraine, Nancy, France
[2]Bordeaux population health center, U1219, Inserm, University of Bordeaux, Bordeaux, France
Contact: amandine.vallata@univ-lorraine.fr

Background:

Policies and programs implemented to promote smoking cessation among youth present disparate results. These variations are explained by interventions themselves but also by context, population and implementation characteristics. Our objective was to analyze these factors, related to enrollment and participation in a smoking cessation program, implemented in vocational or technical schools.

Methods:

Population factors were studied by a systematic review about determinants of smoking cessation among 10-24 years old, updating a previous one.

Contextual and implementation factors were identified by a qualitative multiple cases study. A smoking cessation program, TABADO, had been implemented in 3 regions in France, in 10 vocational or technical schools (1 school/1 case). Data collection included 51 observations, 46 semi-structured interviews, and 3 interdisciplinary seminars.

Results:

The review identified 46 factors probably or possibly related to a successful smoking cessation, both individual (e.g. smoking frequency) and collective (e.g. relationship smoking status, anti-tobacco legislation). The case study allowed us to objectify positive or negative factors that influence the enrollment and the participation in the program (e.g. presence of a referent in the school, combination with the school program). Finally, we identified prerequisites to gather before starting such a program.

Conclusions:

This mixt design highlights factors on which we must focus to increase the success of a smoking cessation program for youth. A key factor is to tailor intervention and implementation modalities to the local context. Results enabled us to product a pragmatic guide, TABADO 2, which is now used in a national scaling process. They also will be used to build an intervention theory, which could be used for any smoking cessation intervention for youth.

Acknowledgments: The TABADO IDF study group, Inca, the région Lorraine and the ARS Nouvelle-Aquitaine for their financial support.

Key messages:

- A smoking cessation program must be a global strategy, considering contextual, population and organizational factors.
- Instead of trying to strictly apply a protocol, a complex intervention must be tailored to the context in which it is implemented.

Participation of medical students in prevention actions: first year of implementation in France

Marie Herr

M Herr[1,3,5], *M El Kassouani*[4], *A Labbe*[5], *L Josseran*[1,2,5]
[1]Département Hospitalier d'Epidémiologie et de santé publique, Hôpitaux Univ Paris IDF Ouest, Garches, France
[2]EA4047, Université de Versailles st Quentin, Montigny le Bretonneux, France
[3]UMR 1168, Université de Versailles st Quentin, Montigny le Bretonneux, France
[4]ARS 78, Versailles, France
[5]UFR Simone Veil-Santé, Montigny le Bretonneux, France
Contact: marie.herr@uvsq.fr

Background:

Prevention has become an essential part of the health policy in France. Since the autumn 2018, medical students, as well as students in midwifery and paramedics, are required to take part in prevention actions in population. This prevention training is mandatory and aims to increase the number of prevention actions in population and to sensitize medical students to the importance of prevention. National guidelines were published to guide the implementation of this training.

Objectives: This communication aims to describe the implementation of this prevention training in the medical school of University Versailles Saint-Quentin-en-Yvelines in France.

Results:

A total of 155 students in third year of medical school were included in the training (2018/2019). The first step was the creation of e-learnings in 9 domains related to prevention: prevention policy in France, communication, project management, addictions, nutrition, physical activity, sexual education, prevention for the children and prevention for the elderly. They were elaborated by medical doctors of different specialties, public health professionals, nurses, and physiotherapists. The second step was the recruitment of voluntary settings to perform prevention acitons. They were mainly schools (n = 24), but also institutions for disabled children or adults (n = 8), health forums (n = 4), the university health center and the local center for social reintegration of young people. The types of actions performed by the students will be presented at the conference.

Conclusions:

Preliminary results indicate a positive feedback from both the students and the voluntary settings. At this stage, recommendations for the future can already be drawn, such as the inclusion of specific training sessions to lead group sessions of various ages or interdisciplinarity in the actions.

Key messages:

- The participation of medical students to prevention actions in population has become mandatory in France.
- Voluntary settings were mainly schools, but also institutions for disabled children or adults.

Relevance of the health insurance databases to study potentially inappropriate prescriptions

Marie Jardin

M Jardin[1], *MC Banide*[2], *G Saba*[2], *E Burlot*[2], *F Jozancy*[3], *V Guagliardo*[1], *P Verger*[1,4,5]
[1]Southeastern Health Regional Observatory (ORS Paca), Marseille, France
[2]Southeastern Regional Medical Department for Health Insurance Fund (DRSM Paca-Corse), Marseille, France
[3]Southeastern Regional Union of Private Practitioners (URPS-ML Paca), Marseille, France
[4]Aix Marseille University, IRD, AP-HM, SSA, Vitrome, Marseille, France
[5]IHU-Méditerranée Infection, Marseille, France
Contact: marie.jardin@inserm.fr

Issue/problem:

Potentially inappropriate prescriptions (PIP) for the elderly constitute a major issue in the quality of ambulatory care. In France, people aged 80 years or older use on average five drugs per day. This polypharmacy is justified in most cases by multimorbidity but it increases the risk of adverse events.

Description of the problem:

In order to optimize general practitioners' (GPs) prescribing practices for the elderly, a project involving the Southeastern Health Regional Observatory (ORS Paca), the Regional Medical Department of Health Insurance Fund (DRSM Paca-Corse) and the Regional Union of Private Practitioners (URPS-ML Paca) was conducted in 2014-2016. Its main objective was to set up a regional mapping tool giving GPs access to drug prescriptions indicators for the elderly in their practice area.

Results:

Based on national guidelines and advice of experts in the field, we calculated 7 different indicators of potentially inappropriate prescriptions (PIPs) for people aged 65 years or older, using drug reimbursement data from the Health Insurance Fund. Those indicators were calculated among patient lists of GPs and covered prescriptions of benzodiazepines, non-steroidal anti-inflammatory (NSAI) drugs, new oral anticoagulants, proton pump inhibitors, antiplatelet therapy... PIPs' prevalence were calculated among GPs' lists of patients. PIPs prevalence differed between drugs type, GPs and territories: for example, the age standardized prevalence of long-term treatment with NSAI drugs varied in 2014 from 2 to 15% between municipalities and from 0 to 14% in 2017.

Lessons:

These results allowed to identify priority areas for intervention, in which continuous medical education sessions with an individual feedback to GPs on their own indicators were implemented, to improve prescribing practices.

Key messages:

- A substantial proportion of elderly people receive PIPs.
- Medico-administrative databases can be used to produce indicators of prescription practices to be used to guide public health interventions.

Complexity in managing the blood transfusion process: experience of an Italian Academic Hospital

Marco Poletto

M Poletto[1], E Scarpis[1], B Bianchet[1], E Ruscio[1], S Degan[2], F Farneti[2], V De Angelis[3], S Brusaferro[1,2]
[1]Department of Medicine, University of Udine, Udine, Italy
[2]Udine Healthcare and University Integrated Trust, Udine, Italy
[3]Transfusion Medicine Department, Udine Healthcare and University Integrated Trust, Udine, Italy
Contact: polettomd@gmail.com

Issue:

Blood components transfusion is a high-risk process due to its complexity and possible consequences in case of error. Preventing mistakes and acting promptly if they occur is a duty of healthcare organizations. The Italian Ministry of Health has drafted a specific recommendation with the aim of reducing transfusion errors.

Description of the problem:

Following a transfusion error occurred in July 2018, a multidisciplinary group including professionals from Clinical Risk Unit (CRU) and Transfusion Department of the Academic Hospital of Udine, carried out an analysis of the blood components issuing process. The 20 most critical steps were identified and grouped into 3 areas: 1)single samples processed individually, 2)appropriate application compliance, 3)environmental interferences. For each step shared solutions were identified and then implemented as new standard practices. From February to March 2019, CRU randomly observed 23 blood components assignments using tracer methodology, evaluating staff's compliance with the new recommended practices (NRP).

Results:

For the sample processing (area 1, n.10 practices), adherence to all ten NRP was 100% (26/26). For the appropriate application compliance (area 2, n.8 practices), adherence to 7 NRP was 100% (11/11), whereas for one (punctual registration of non-conformities) adherence was 86% (6/7). For the environmental interferences (area 3, n.2 practices), adherence to one practice was 100% (2/2), whereas for the other one (avoid answering to incoming phone calls) adherence was 75% (3/4). Overall, professionals behaviour was consistent with the NRP in the observed period.

Lessons:

Identification of critical issues by a multidisciplinary team and measuring the adherence to new practices is crucial in managing the complexity of blood transfusion process.

Tracer methodology, used by CRU to verify adherence to new standard, also allows the hospital to monitor the progress of the achieved performances over time.

Key messages:

- Multidisciplinary analysis of the blood transfusion process and shared development of new standard by all professionals favours their compliance in the practice.
- Tracer methodology is a useful tool to evaluate adherence to recommended practices and monitor the complexity of transfusion process over time.

Roma health mediators in Serbia – good example of multisectoral cooperation in health promotion

Milena Vasic

B Kilibarda[1], M Vasic[1], V Knjeginjic[2]
[1]Institute of Public Health of Serbia, Belgrade, Serbia
[2]Ministry of Health of Serbia, Belgrade, Serbia
Contact: milena_vasic@batut.org.rs

Issue:

Within the framework of the JA CHRODIS plus participants of the WP5 worked on identification of factors that contribute to collaboration within healthcare and between the broader health system and other sectors, as well as their enablers and barriers. In Serbia, practice that was identified and elaborated was aimed at improvement of health of Roma population.

Description of the problem:

Based on available data, health indicators among Roma population in Serbia were two to three times worse than national averages. In order to tackle this issue, government of the Republic of Serbia, started with implementation of the project of education and inclusion of Roma health mediators in the health system. This project has been implemented in Serbia since 2009. Roma Health mediators (Roma ethical minority females) were trained for fast and efficient provision of support to Roma families.

Results:

As a result of the project there was increased number of visits to health institutions and preventive check-ups of target population. Established cooperation between Roma health mediators and other health professionals in centers for primary health care, social care, and local self-government helped them in fulfilling their tasks, but also built capacity of other service providers to work in Roma communities. Through trainings they increase knowledge on various health, social and child care topics.

Lessons:

Capacity building and inclusion of memebrs of vulnerable population into health promotion of the own to this population in terms of better acceptance of specific population population is useful to access groups as they can better understand and adapt to the needs of groups they want to reach. They should have opportunity to share their experience and lessons learned with experts involved in planning interventions for other vulberable groups.

Key messages:

- Building capacity of Roma mediators empowers them for integration into society beyond the scope of the Project.
- Lessons learned should be used for planning further actions for vulnerable groups.

Evaluation of Austrias first PHC: What lessons can be learned?

Brigitte Piso

B Fröschl[1], K Antony[1], S Ivansitis[1], B Piso[1]
[1]Gesundheit Österreich GmbH, Austrian Public Health Institute, Vienna, Austria
Contact: brigitte.pisol@goeg.at

Issue/problem:

The Austrian health care system regularly shows high performance. While about 99.9% of the population is covered by the compulsory health insurance system, the system is highly fragmented with shared responsibilities for inpatient and outpatient care.

Description of the problem:

Primary health care in Austria is mainly provided by general practitioners (GP) in solo practises with average opening hours of 16-20 hours a week. This leads to high frequencies in outpatient care departments of hospitals and secondly to inefficiencies due to a high level of uncoordinated care. Thus in June 2014, the Federal Target-Based Governance Commission adopted a new concept for providing primary Health Care in an integrative, quality-assured manner and steering patients to the Best Point of Service. PHC centres are providing care in a multiprofessional approach (psychologists, nutritionists, and nurses) and have significantly longer opening hours with 45 hours per week.

Results:

In 2015, the State Target-Based Governance Commission of Vienna commissioned the Austrian Public Health Institute (Gesundheit Österreich GmbH) with the evaluation of these pilot centers. The evaluation results of the first two years of the first PHC center shows a high level of satisfaction with the services provided by PHC and high level of utilisation, indicating an improvement in the service offered. PHC patients show a significantly higher level of utilisation of general medical care and at the same time a lower level of utilisation of specialist medical care than patients of the control group. Furthermore PHC patients have a significantly lower frequency of contacts in general emergency outpatient clinics.

Lessons:

Changes in structural conditions such as the expansion in the range of services and the provision of care by a multiprofessional team results in advantages for patients, the team and the utilization of services at the best point of service.

Key messages:

- PHC centers can lead to a lower utilization of outpatient departments and thus to an improvement in the coordination of care.
- Cooperation in multi-professional teams can lead to a relief of the physicians and a higher job satisfaction.

Why declare events? What to draw from experience feedback?

Isabelle Nicoulet

I Nicoulet[1], A Isambert[1]

[1]Bureau des Expositions en Milieu Médical, Autorité de Sureté Nucléaire, Montrouge, France

Contact: isabelle.nicoulet@sfr.fr

Issue:

In France, the reporting of significant radiation events for nuclear activities is a mandatory system since July 2007 following the accident of oncology in Epinal. Later, the directive 2013/59/EURATOM states that Members of the European Union shall ensure that a system of experience feedback is in place for the dissemination of lessons. In France, it was implemented in 2011 through the publication of a newsletter, ‘‘Patient safety: Paving the way for progress’’ on radiotherapy, it is now extended to medical imaging. Until 2015 the number of reported events was stable but steadily decreasing in radiotherapy since 2016. Lack of time to report, lack of awareness and training of doctors, fear of consequences in terms of communication on the establishment that reports and in terms of control by the ASN following the report may explain the decrease. Educational actions need to be lead to reaffirm the objectives of reporting and reinforce the interest of experience feedback. The French Nuclear Safety Authority decide to focus a newsletter on international reporting systems and Experience feedback based on the reflections of a French institutional working group.

Results:

According to professionals it is sometimes difficult to report an event with impact on patients, easier to work on near miss and even easier to work on events happening elsewhere. Reporting an incident is thus a collective action. The experience feedback process allows learning in order to improve practices in the future and address three aspects: Benchmarking, Prospective risk analysis for the techniques/devices which have never been used in a centre, Analysis of concrete cases during feedback experience meetings. The limit of the current systems is the difficulty in finding precise information due to shortcomings in its structure. A simplified system is needed.

Lessons:

Reporting events on websites highlight new events and enable the solutions implemented elsewhere to be disseminated in our own networks.

Key messages:

- Reporting adverse events or near miss has a collective impact.
- Experience feedback allows dissemination of lessons and prevents incidents.

Survey-based experiential learning - means of raising professional awareness in developing countries

Ruhija Hodza-Beganovic

R Hodza-Beganovic[1,2], P Berggren[1,3], K Hugelius[2], S Edelbring[2]

[1]International Medical Program-IMP, Centre for Teaching and Research in Disaster Medicine, Region Östergötland, Linköping, Sweden

[2]School of Health Sciences, School of Health Sciences, Örebro, Sweden

[3]Linköping University, Linköping University, Linköping, Sweden

Contact: Ruhija.Hodza-Beganovic@regionostergotland.se

Background:

Healthcare in post-war Balkans is still under development. Healthcare changes towards more complex clinical scenarios that need different competencies around patients. This study reports on survey based learning to increasing professional awareness for developing sustainable healthcare settings using an experiential learning approach.

Methods:

In this study, researchers and educators identified non-technical skills concepts on individual, team, and organizational levels. These concepts were contextualized into the local setting through interactive workshops. Two pediatric surgery clinics in Kosovo and Bosnia and Herzegovina participated who were part of an international clinical skills training project. The tools and surveys were: Johari window, Kolb’s learning style questionnaire, team members exchange quality scale, the IPEC framework for interprofessional competence, Team STEPPS observation tool and organizational models.

Results:

A model is developed for contextualizing core concepts on professional awareness into a local developing healthcare setting. It entails three steps conducted in consecutive workshops:

Identifying research-based concepts on professional competence on individual, team and organizational levels. Facilitating local contextualization of these concepts by using surveys in interactive workshops. Agreeing on indicators to maintain high professional awareness.

Conclusions:

Capacity-building in public health can be conducted through increasing professional awareness. Professional awareness can be approached in individual, team and organizational dimensions. Established core concepts of non-technical skills can be contextualized in other cultures through a survey-based experiential learning approach.

Key messages:

- Professional individual, team and organizational awareness is a vital part of conducting efficient healthcare.
- The professional awareness can be enhanced through processing core concepts in a local context through facilitated workshops.

Challenges in handling congenital anomalies clusters: a recent mediatic example in France

Nolwenn Regnault

N Regnault[1], N Beltzer[1], J Boudet-Berquier[1], E Gomes[1], E Bauchet[1], A Gallay[1], limb reduction cluster investigation group[2]

[1]Non Communicable Diseases and Trauma Direction, Santé Publique France, St Maurice, France
[2]DIRE, DATA, DSET, DAC, Santé Publique France, St Maurice, France
Contact: nolwenn.regnault@santepubliquefrance.fr

Issue:

In 2018 in France, reports of aggregated cases of isolated transverse limb reduction defects, a rare congenital anomaly (1.7 for 10,000 total births) generated a large mediatic interest with environmental factors overtly pointed out. Our aim is to describe the investigations carried out and to share the challenges we met.

Description of the response:

Over a period of 5 years (2010-2015), 3 aggregates were signaled by health professionals in 3 different areas in France. Investigations included case ascertainment, epidemiological analyses, and search for a common exposure. Standardized Incidence Ratios were computed using the 6 French registries's data as reference. In one area, the local registry performed a concurrent analysis using satscan. Parents filled a questionnaire addressing environmental and occupational exposures. Environmental databases were consulted as well as animal health surveillance data.

Results:

Fourteen cases met the case definition. The excess of cases was ascertained in two aggregates located in a two small towns in the western part of France and comprising respectively 3 children born in 2007-2008 (SIR: 87.8 CI95%:[17-256]) and 4 children born in 2011-2013 (79.8 [2.5-204.2]). The third signal included 7 cases born between 2009 and 2014 residing in 7 towns located above the Alps and did not yield a significant excess when related to expected cases in the administrative subdivision (0.94 [0.38-1.95]). The concurrent analysis found a significant excess, generating a lengthy debate. None of the investigations identified a common cause or notable exposure. Delayed feedback and negative conclusions led to incomprehension among families.

Lessons:

Informing stakeholders timely is crucial but communicating effectively about methods used and negative results can be challenging.

Key messages:

- Congenital anomalies clusters are sensitive topics.
- Cluster investigations involve a scientific and a societal component that must both be taken into account in organizing the public health response.

Carbapenemase-producing Enterobacteriaceae (CPE) patient notification exercise

Lindsey Murphy

L Murphy[1], L Tysall[1], L Wellington[1], L Guthrie[1], D Inverarity[1], L Willocks[1], E Czarniak[1], A McCallum[1], T Gillies[1]
[1]Incident Management Team, NHS Lothian, Edinburgh, UK
Contact: lindsey.murphy@nhslothian.scot.nhs.uk

Issue:

CPE has become endemic in many European countries. Scotland has few locally acquired cases at present and interventions are aimed at minimising transmission of CPE into acute hospital settings.

Description of the problem:

NHS Lothian held an incident management team (IMT) following the transmission of CPE in an inpatient setting. Initial management of the incident included informing and screening all inpatient contacts, enhanced infection control precautions and staff education. The IMT considered whether to inform and screen patient contacts who had been discharged. A literature review was carried out and teams in the UK who had considered patient notification exercises for CPE were contacted. This highlighted variation in approach.

The IMT assessed whether a patient notification exercise was required and considered:

- The need to reduce the risk of CPE transmission in acute hospitals by screening and isolating community contacts on readmission to hospital.
- The ethics of raising patient anxiety around CPE transmission with limited options for effective treatment.
- Risk stratification to identify contacts at highest risk.
- Information Governance: electronic tagging of case notes if patients have not been informed.

Results:

The IMT agreed that a patient notification was appropriate. Contacts were risk assessed to determine those at greatest risk of CPE transmission. After speaking to GPs, 33 patients were sent letters. No screening of community contacts was advised unless they were re-admitted to an acute hospital or resided in a care facility. No further CPE reports have been linked to the situation.

Lessons:

The IMT worked through the issues systematically to protect the public's health without infringing their rights. The IMT advised that the Scottish CPE toolkit should be revised to support future Incidents including how to analyse transmission pathways, undertake patient notification exercises and meet public health ethics standards.

Key messages:

- There needs to be clear guidance on how to manage contacts of patients with CPE once discharged from hospital.
- Team work between Public health and Infection control is essential in manageing incidents of CPE in hospitals.

An objective structured clinical examination to assess the communication skills of students

Vitaliy Koikov

Z Bekbergenova[1,2], G Derbissalina[1], A Umbetzhanova[1,2], G Alibekova[1], G Mauletbayeva[1], D Akhmetova[1], D Zhunussova[1], V Koikov[2]
[1]NCJSC ''Astana Medical University'', Astana, Kazakhstan
[2]RSE on the REM, Astana, Kazakhstan
Contact: vitaliy.koikov@gmail.com

Background:

Communicative competence is one of the important components of professional competence that needs to be developed in the process of training future doctors.

Methods:

At the end of the study of the ''General Practice'' module, students of the 5th year of the specialty General Medicine must pass a two-stage exam consisting of comprehensive testing and acceptance of practical skills of an objective structured clinical exam (OSKE) with the participation of volunteers. Students, who passed the exam, anonymously filled out the questionnaire on the evaluation of the organization of the OSKE with volunteers and their communication skills.

Results:

The analysis of the questionnaires showed that 4% of the students noted the unfriendliness of the volunteers, 27% wrote that it was difficult to engage with the volunteers in the collection of the anamnesis, 2% of the students, unfortunately, had never before encountered a similar situation. 12% of students who passed the exam wished to improve the communication skills of the volunteers themselves, for example, they advised to speak louder, not to ask unnecessary and unnecessary questions, to get more real in the role of the patient. Only 10% of examinees decided that OSKE did not develop their communication skills; 24% noted individual stations, which caused them some difficulties. However, the students themselves acknowledged their poor preparedness, including during communication with standardized patients.

Conclusions:

The analysis of the questionnaires showed that the students themselves are self-critical of their communication skills and recognize the need for their continuous improvement.

Key messages:

- The student's communicative competence can be assessed by conducting an objective structured clinical examination.

- Conducting an objective structured clinical examination with volunteers can improve the communicative competence of students.

Benefits from a tabletop exercise in a Heat-Health Action Plan in Amadora, Portugal

Miguel José Cabral de Pinho

M Cabral[1], *A Leite*[1,2], *E Freire Rodrigues*[1], *D Vaz*[1], *E Calé*[1], *A Silva*[1]
[1]Public Health Unit António Luz, ACES Amadora, Amadora, Portugal
[2]Public Health Research Centre, National School of Public Health, Nova University Lisbon, Lisbon, Portugal
Contact: miguelcabralpinho@gmail.com

Issue:

National guidelines for Heat-Health Action Plans (HHAP) in Portugal exist since 2004. These guidelines are further developed and implemented at Local Public Health Units (LPHU) together with local partners. Tabletop exercises are a useful tool to improve preparedness. Despite the long experience with HHAP there has not been any tabletop exercise in Amadora.

Description:

Amadora's LPHU organized a tabletop exercise with local partners to improve HHAP preparedness (12th July 2018). It included: LPHU, city hall, civil protection services, local social services, primary healthcare services, local public hospital, and firefighters. The exercise hypothesized a scenario of an unprecedented increase of temperature for an extended period of time, activating the highest level of warning (red) and action in the HHAP.

Results:

During the exercise several issues were identified. Some partners were not clear about the pathway established for red warnings and partners were not aware of relevant HHAP activities. Also, from the 8 sites listed as climate shelters, only 2 were deemed as adequate for using in this scenario, even though they have been listed for several HHAP. Due to the exercise, it was possible to conduct an inspection of said shelters, which hadn't took place yet due to the lack of resources. It was possible to find out that only one shelter was fit for purpose. Additional private facilities were identified as desirable shelter locations during the exercise. A few weeks later, a red warning was issued and clarification arising from the tabletop exercise was useful to properly implement measures.

Lessons:

Despite the perceived frequent and good communication among partners of the HHAP, several issues - mainly regarding the adequacy of shelters - were identified with a tabletop exercise. It also improved preparedness for the following HHAP warning. As such, tabletop exercises should be promoted within HHAP.

Key messages:

- Despite developing heat-health action plans for several years, with the involvement of community partners, unidentified constraints existed in Amadora, Portugal.
- Tabletop exercises should be used more frequently, as we were able to identify and solve constraints within our heat-health action plan using one.

Formative dialogue research - an appropriate strategy in community public health projects?

Grete Eide Rønningen

L H Ausland[1], *I Stang*[1]
[1]Faculty of Health and Social Sciences, University of South-Eastern Norway, Kongsberg, Norway
Contact: ger@usn.no

Background:

Lately, there has been a call for knowledge-based community public health strategies and for evaluating local public health interventions. In addition to contributing to the public health knowledge base, it is underlined that the evaluations should be formative for ongoing local processes. The community professionals often lack evaluation competency, and a university course (10 ECTS) about process- and self-evaluation has been developed and facilitated for local public health workers. Vestfold County Council and University of South-Eastern Norway have collaborated to develop the course. The course has a particular focus on Formative Dialogue Research (FDR). FDR strategies may emphasize both project impact and processes, and local competences. The FDR approaches also contributes to the public health knowledge base (Rønningen 2010).

Objective:

To examine and discuss whether FDR in combinations with an evaluation course, may be an appropriate strategy to meet the new expectations for community public health evaluations.

Results:

Preliminary results indicate that FDR in combination with a evaluation course, may be an appropriate and desirable approach in community public health projects. The local public health professionals welcome the course. The focus has until now been on the development of the course and the cooperation and dialogues between the university and the county. Questionnaire and interview data collected in September 2019 will exemplify and nuance these preliminary results.

Conclusions:

So far, the developing process indicate that FDR in combination with a course in self- and process evaluation, support FDR as an appropriate evaluation approach in community public health projects and processes.

Key messages:

- The local public health workers often lack competences in project evaluation.
- FDR in combination with a comprehensive course in process and self-evaluation seem appropriate evaluation approaches in community public health projects.

DR Mental health

The role of Emotional Intelligence in health care professionals burnout

Roberta Arnone

R Arnone[1], *MI Cascio*[1], *I Parenti*[1]
[1]CEFPAS, Caltanissetta, Italy
Contact: arnone@cefpas.it

The purpose of this study is to explore the relationship between Emotional Intelligence (EI) and burnout in health care professionals. More specifically, this survey has the purpose of demonstrating the role of EI as a protective factor against the risk of burnout. Health professionals (doctors, nurses, and other caregivers) composed the sample. Health care professionals were invited to complete the following tests: Self Report Emotional Intelligence Test (Schutte et al., 1998; it. ad. Craparo, et al.[35]); Link Burnout Questionnaire,LBQ; Other variables, such as gender, lenght of service (years of professional experience) and organizational department. Major results of this survey underline the relationship between EI and burnout. More specifically, there is a negative and significant correlation between burnout and Emotional Intelligence. Moreover, burnout varies depending on length of service: burnout increases between 5 and 10 years of experience and decreases over 10 years. Indeed, burnout is differently expressed amongst healthcare professionals: more specifically, Psycho-physical exhaustion, Detriment of the relationships and Burnout (total score) impact physician (doctors) more than other investigated health professionals.

These findings seem to suggest the opportunity to improve Emotional Intelligence abilities through specific training programs, useful to promote the ability to cope with stress and to enrich the relationships in the workplace.

Key messages:

- Burnout is more diffuse among health professionals working in emergency departments.
- Emotional intelligence has the role to cope with burnout.

The depression phenotype in a European population-based study

Sarah Cuschieri

S Cuschieri[1], *J Mamo*[2]
[1]Anatomy, University of Malta, Msida, Malta
[2]Public Health, University of Malta, Msida, Malta
Contact: sarah.cuschieri@gmail.com

Introduction:

Depression is a growing public health concern and associated with a number of co-morbidities including diabetes mellitus. The aim was to estimate the prevalence of depression at a population level across different glycaemic statuses while establishing phenotypic characteristics of this sub-population.

Methods:

A national representative cross-sectional study was conducted in Malta (2014-6). Participants were categorized into different sub-populations according to their glycaemic status. Depression prevalence rates and bio-socio-economic characteristics for each sub-population were established. Multiple regression analyses performed to identify links between glycaemic status and depression.

Results:

Depression was prevalent in 17.15% of our study population (CI 95%: 16.01 - 18.36) with a female predominance. The normoglycaemic sub-population had the highest depression rates. Persons with known diabetes had a higher probability of having a history of depression (OR:2.36 CI 95%:1.12 - 4.96), as well as with being of female gender, having lower educational status, smoking tobacco and having established cardiovascular disease.

Conclusions:

Depression was highly prevalent among the normoglycaemic population. Primary care physicians should implement a depression screening tool as part of their routine health check-ups, with special attention to those with cardiovascular co-morbidities and low socioeconomic status.

Key messages:

- Depression prevalent mostly in the normoglycemic population.
- Screening for depression should be part of routine health check-ups.

Depression, anxiety stress and associated factors among university students in France

Karl Herrmann

K Herrmann[1], *P Déchelotte*[2], *J Ladner*[3], *MP Tavolacci*[4]
[1]CIC 1404, Rouen University Hospital, Rouen, France
[2]Department of Nutrition, Rouen University Hospital, INSERM 1073, Normandy University, Rouen, France
[3]Department of Epidemiology and Health Promotion, Rouen University Hospital, INSERM 1073, Normandy University, Rouen, France
[4]CIC 1404, Rouen University Hospital INSERM 1073, Normandy University, Rouen, France
Contact: bareherrmann.karl@gmail.com

Background:

Graduate education is associated with many life changes and stressful events for students, potentially causing depression, anxiety and stress. Prevalence of these disorders and potential associated factors are not clearly identified.

Methods:

A cross-sectional study was conducted among university students in France. The students filled out a self-questionnaire recording depression anxiety and stress with the DASS21. High” and “very High” intensity symptoms were grouped into “presence” of depression, anxiety and stress and “moderate” “light” “normal” were grouped into “absence” of depression, anxiety and stress. Curriculum, perceived academic pressure, financial difficulties, smoking, binge drinking and eating disorders were also recording.

Results:

A total of 1,202 students were included of which 17.8% were healthcare students. The sex ratio (M:F) was of 0.42 with a mean age of 20.0 years. Prevalence of depression, anxiety and stress were respectively 16.4%, 26.4% and 16.0%. After multivariate analysis, female gender was associated with presence of stress (AOR = 1,41 IC 95% [1,03-1,93]). High level of perceived academic pressure (AOR = 2,13 [1,61-2,82], 2,05 [1,57-2,68], 2,35 [1,72-3,22]) financial difficulties (AOR = 1,33 [1,03-1,73], 1,54 [1,19-1,99], 1,37 [1,04-1,82]) and eating disorders (AOR = 2,46 [1,83-3,31], 2,36 [1,75-3,19], 2,21 [1,63-23]) were associated with presence of depression, anxiety and stress. Binge drinking (AOR = 1,48 [1,05-2,09]) and smoking (AOR = 1,46 [1,01-2,13]) were associated with anxiety.

Conclusions:

These results show prevalence of depressive, anxiety and stress symptoms among students. Poor mental health is related to academic and financial difficulties, and is associated especially with eating disorders. There is a pressing need to prioritize mental health of college students through the national public health policies. Additional studies are needed to better understand the relationships between these different factors.

Key messages:

- There is a significant prevalence of depression, anxiety and stress symptoms among Rouen students.
- Depression, anxiety and stress symptoms among students are associated with high level of perceived academic pressure, financial difficulties and presence of eating disorders.

Depressive symptoms and suicidal ideation among medical students: a cross-sectional survey in Turin

Giuseppina Lo Moro

G Lo Moro[1], *F Bert*[1], *E Olivero*[1], *P Rossello*[1], *A Corradi*[1], *S Barello*[1], *P Leombruni*[2], *MR Gualano*[1], *R Siliquini*[1]
[1]Department of Public Health Sciences, University of Turin, Torino, Italy
[2]Department of Neurosciences, University of Turin, Torino, Italy
Contact: giusylomoro@gmail.com

Background:

A high prevalence of mental illnesseshave been detected in medical students (MS) during college. The aim of this study was to evaluate depressive symptoms (DS) and suicidal ideation (SI) in MS and estimate factors that can influence these conditions.

Methods:

In November 2018 a cross-sectional survey was conducted at the School of Medicine of Turin, Italy. The questionnaire consisted of a 30-item sociodemographic part and 3 psychometric tests, including the Beck Depression Inventory II (BDI-II). Overall, 506 surveys were collected. Multivariable logistic regressions were performed mainly. The significance level was $p \leq 0.05$.

Results:

Females were 65% and median age was 22 (IQR 19-24). Median BDI-II score was 9 (IQR 4-15). Presence of DS (BDI-II score>13) and of SI was found in 29% and 15% of the sample, respectively. Preliminary results showed that females (OR 2.03, CI: 1.16-3.56), non-heterosexuals (OR 2.69, CI: 1.49-4-84), participants negative about their college choice (OR 4.79, CI:

2.78-8.26) had a higher risk to report DS. MS who consider unsatisfying their friendships with classmates had a higher likelihood of reporting DS and SI (OR 3.10, CI: 1.16-8.30; OR 2.91, CI: 1.10-7.68, respectively). While the opposite was for those with good economic condition (OR 0.39, CI: 0.16-0.91; OR 0.21, CI: 0.09-0.52, respectively) and those practicing sports more than 90 min/week (OR 0.60, CI: 0.37-0.99; OR 0.47, CI: 0.25-0.89, respectively). Choosing Medicine for profit was related to a higher risk of reporting SI (OR 3.36, CI: 1.43-7.92), having a good family bond to a lower risk instead (OR 0.42, CI: 0.20-0.84).

Conclusions:

Since depression is the leading cause of disability worldwide, it has to be a public health priority in Europe. It is essential to consider MS as at risk and set up interventions to improve factors surrounding them and help them to face difficulties in personal and academic life, without forgetting that they will be the future health professionals.

Key messages:

- Females, non-heterosexuals, students negative about Medical School choice and students unsatisfied with their friendships with classmates had a higher risk of reporting depressive symptoms.
- Students unsatisfied with their friendships with classmates and students who chose Medical School for profit had a higher risk of reporting suicidal ideation.

Development and preliminary psychometric properties of Mental Health Promotion Scale

Hasibe Kadioglu

H Kadioglu[1], S Karaca[2], N Eren[3], S Yurt[4]
[1]Public Health Nursing, Marmara University, Istanbul, Turkey
[2]Psychiatric Nursing, Marmara University, Istanbul, Turkey
[3]Psychiatry, Istanbul University, Istanbul, Turkey
[4]Public Health Nursing, Maltepe University, Istanbul, Turkey
Contact: hasibek@gmail.com

Background:

There is no valid and reliable scale for assessing mental health promotion ability for adults in Turkish language. The purpose of this study was to develop a scale to mental health promotion ability for adults and to test the validity and reliablity of this scale.

Methods:

This methodological study was conducted in Istanbul over the period October 2016- May 2018. The three rounds of the Delphi study were cunducted to develop the items of the scale and to determine the content validity. Thirty- three experts were participated in the Delphi study. A convenience sample of 452 adult people was recruited. The scale was tested for construct validity with Exploratory Factor Analysis (EFA), after which the scale's reliability was evaluated for item-total correlations using Pearson's correlation analysis and for internal consistency with Cronbach's Alpha.

Results:

At the end of the first Delphi round, 160 items were compiled. Experts reached consensus on 93 items of scale at the end of the third Delphi round. In the first EFA, twenty two factors with eigenvalues greater than 1 explained 65.2% of the total variance. Items with factor loadings of less than .30 and those that appeared in more than one factor with differences of less than %10 were removed from the scale one by one and the analysis was repeated. In the last EFA of the 47-item scale, twelve factor was found with an eigenvalue greater than 1 that explained 64.3% of total variance. The scale's item-total correlations ranged between .36 - .62 and Cronbach's coefficient alpha was calculated to be .93.

Conclusions:

This scale was found to be valid and reliable. It can be used to assess the mental health promotion ability of adults who native Turkish speaker.

Key messages:

- The Mental Health Promotion Scale has been found to be valid and reliable.
- The Mental Health Promotion Scale can be used to assess of mental health promotion ability for adults.

Antidepressant use in over-indebted individuals compared to the general population in Germany

Jacqueline Warth

J Warth[1], N Beckmann[1], M-T Puth[1,2], J Tillmann[1], J Porz[1], U Zier[1], K Weckbecker[3,1], B Weltermann[1], E Münster[1]
[1]Institute of General Practice and Family Medicine, University of Bonn, Bonn, Germany
[2]Department of Medical Biometry, Informatics and Epidemiology, University Hospital Bonn, Bonn, Germany
[3]Institute of General Practice, Heinrich Heine University Düsseldorf, Düsseldorf, Germany
Contact: jacqueline.warth@ukbonn.de

Background:

About ten percent of European households across all socio-economic groups are considered over-indebted due to ongoing difficulties meeting financial commitments and living expenses. Studies found an association between over-indebtedness and physical and mental health such as depression independent of standard socioeconomic status measures. However, antidepressant use in the over-indebted population has been understudied. In view of the substantial economic and social burden of mental illness in Europe, the aim of this study was to examine the association between over-indebtedness and antidepressant use in Germany to advance the understanding of socioeconomic inequalities in mental health.

Methods:

We conducted a cross-sectional survey among clients of 70 debt advice agencies in North Rhine-Westphalia, Germany, in 2017 (OID), and merged data with the first wave of the German Health Interview and Examination Survey (DEGS1) representative of the general population. We used descriptive statistics and multiple logistic regression analysis to examine antidepressant use in the previous 7 days (OID: n = 699; DEGS1: n = 7115).

Results:

Antidepressant use was more frequent in the over-indebted (12.3%) compared to the general population sample (5.0%). After adjustment for age, sex, education, employment, marital status and chronic disease, over-indebted respondents were more likely to use antidepressants than the general population sample (aOR 1.83; 95% CI 1.35-2.48).

Conclusions:

Prevalence of antidepressant use was higher in the over-indebted compared to the general population. The association between over-indebtedness and antidepressant use cannot be fully explained by standard socioeconomic measures. Over-indebtedness reflects a relevant public health issue that needs to be addressed in health care, social policy and research. There is an urgent need to develop public health activities that specifically target those at risk of mental illness and over-indebtedness.

Key messages:

- Over-indebtedness is associated with antidepressant use.
- Public health interventions are needed to prevent adverse health effects of over-indebtedness and safeguard access to care according to need.

Mapping of early intervention programs for psychosis in France in 2018

Anne Duburcq

L Courouve[1], A Duburcq[1], G Gozlan[2], S Meunier-Cussac[3], L Lecardeur[3], MO Krebs[4]
[1]CEMKA, Bourg-la-Reine, France
[2]SAMSAH PREPSY, Paris, France
[3]EMSI, CHU de Caen, Caen, France
[4]CJAAD, GHU Saint-Anne, Paris, France
Contact: anne.duburcq@cemka.fr

Early intervention programs (EIP) have been developed in many countries (United States, Europe, Canada) and are now widely considered effective in the treatment of early psychosis. In France, current national policies in the field of mental health promote the development of early intervention but France has not yet met national standards of care for EIP. A recent report from the London School of Economics (2016) even mentioned the delay of France in this area, referring to only one EIP in the country. A preliminary investigation conducted in 2017 showed a strong dynamic with many ongoing projects which led us to renew this investigation in 2018.

This was a two-phase study. First, an inventory was achieved through a bottom-up approach and many contacts across the country which may either provide this kind of care or know of such initiatives: psychiatrists, healthcare facilities or Health Regional Agencies. Then, an online declarative survey was administered covering structure of attachment, dedicated team, funding, targeted population, activity in 2017, difficulties and prospects. Between May and October 2018, 69 EIP were identified in France: 35 were operational and 34 were being established or beginners. The 35 identified operational programs were located throughout the country with a few disparities. Half of the programs had been existing for 2 years (17/35). All programs operated with multidisciplinary teams, including at least one psychiatrist and with a mean of 5.9 dedicated full-time equivalents workers. Half of the programs offered case management (48.6%). Most programs were not as a specific setting and had mixed activities, including chronic patients with schizophrenia and most programs offered an integration of ambulatory follow-up in the living environment for some patients (77.1%).

A real dynamic has been launched in France. This study will help to improve visibility of programs and to harmonize and ensure a high level of care.

Key messages:

- This study shows that a real dynamic has been launched in France.
- This study shows a need for teams to harmonize and standardize practices of care.

Relationship between burnout and work engagement among Sri Lankan collegiate cycle students

Nuwan Wickramasinghe

N Wickramasinghe[1], *D Dissanayake*[2], *G Abeywardena*[3]
[1]Department of Community Medicine, Faculty of Medicine and Allied Sciences, Rajarata University of Sri Lanka, Anuradhapura, Sri Lanka
[2]Department of Community Medicine, Faculty of Medicine, University of Peradeniya, Peradeniya, Sri Lanka
[3]Psychiatry Unit, Teaching Hospital Kandy, Kandy, Sri Lanka
Contact: nuwick74@yahoo.com

Background:

Keeping on par with the emerging trend towards positive psychology focusing on optimal functioning, burnout research is also associated with a shift towards its positive antipode; work engagement. This study was aimed at determining the relationship between burnout and work engagement among collegiate cycle students in Sri Lanka.

Methods:

A school-based, cross-sectional study was conducted among 872 grade thirteen students in 15 government schools in the Kegalle district, Sri Lanka. The validated Sinhala versions of the 15-item Maslach Burnout Inventory-Student Survey and the 16-item Utrecht Work Engagement Scale-Student Version were used to assess burnout and work engagement respectively. The relationship between subscales of burnout; viz., exhaustion (EX), cynicism (CY) and reduced professional efficacy (rPE); and subscales of work engagement; viz., vigor (VI), dedication (DE) and absorption (AB); were assessed using Pearson product-moment correlation coefficient.

Results:

The response rate was 91.3%. The EX subscale of burnout had strong negative correlations with VI ($r = -0.699$) and AB ($r = -0.642$) subscales and a moderate negative correlation ($r = -0.475$) with DE subscale of work engagement. The CY subscale of burnout had a strong negative correlation with AB subscale ($r = -0.577$), a moderate negative correlation with VI subscale ($r = -0.391$) and a weak negative correlation ($r = -0.195$) with DE subscale. The rPE subscale of burnout had weak negative correlations with DE subscale ($r = -0.218$), AB subscale ($r = -0.206$) and VI subscale ($r = -0.128$). All these correlations between the subscales of burnout and work engagement were statistically significant ($p < 0.001$).

Conclusions:

Given the significant negative correlation between burnout and work engagement, exploring student work engagement may allow identification of their positive psychological characteristics that can be incorporated in formulating packages for preventing burnout.

Key messages:

- Bivariate correlation revealed that all three subscales of burnout had statistically significant negative correlations with all three subscales of work engagement.
- Exploring student work engagement may allow identification of their positive psychological characteristics that can be incorporated in formulating packages for preventing burnout.

MENTAL HEALTH ACT, MALTA 2012 - A personal reflection on 5 years working with a new legal framework

John M Cachia

JM Cachia[1,2,3]
[1]MAPHM, Msida, Malta
[2]Commissioner for Mental Health, Office of the CMH, G' Mangia, Malta
[3]Department of Public Health, Faculty of Medicine, University of Malta, Msida, Malta
Contact: john.cachia@um.edu.mt

The Commissioner for the Promotion of Rights of Persons with Mental Disorders (CMH) was established in Article 5 of the Mental Health Act approved by the Maltese Parliament in December 2012. The whole Act was completely in force on 10th October 2014.

The involuntary care process is being closely monitored. Patients are being followed up within the time-frames established by the new law. Although not strictly comparable, length of stay in involuntary care has diminished radically. Patients are being discharged from compulsory treatment orders or transferred to community treatment orders rather than being left on ''leave of absence''. Community involuntary care is the preferred option of following up difficult cases. This shift requires commitment to strengthen community support services and render them sustainable.

The applications for involuntary care are progressively being better completed and the quality of the information backing requests for involuntary detention of persons is improving. Care plans are being submitted, but their completeness and their quality merits revision. The issue of availability of human resources is a critical issue which regularly features in feedback with care teams. Evidence of greater involvement of patients and responsible carers in the care planning process should be better documented if it is indeed happening. The level of awareness of patients' rights in terms of the Act merits deeper evaluation.

The CMH must continue to provide a voice to vulnerable persons with mental disorders and their loved ones. Maximization of the potential of persons with mental disorders is not only a question of social justice but also critical for the sustainability of our health system and the prosperity of our society. The burden of mental disorders is increasing exponentially with the modernization of our society and those who are not coping with this burden merit active consideration and support.

Key messages:
- Public health advocacy and the improvement of patient rights.
- The use of legislative tools in reforming service delivery.

Building Resilience in Adolescents and Youths - The Maltese Scene

John M Cachia

JM Cachia[2,1,3]
[1]MAPHM, Msida, Malta
[2]Commissioner for Mental Health, Office of the CMH, G'Mangia, Malta
[3]Department of Public Health, Faculty of Medicine & Surgery, University of Malta, Msida, Malta
Contact: john.cachia@um.edu.mt

The Office of the Commissioner for Mental Health in Malta was established in 2011 to promote and protect rights of persons with mental disorders and their carers. This advocacy role includes monitoring of involuntary care, regular reporting on quality of care and care environments, in-depth analysis and recommendations on emerging issues such as mental health literacy, multidisciplinary care plans, drug addiction services and stigma and regular networking across ministries, agencies, departments, and NGOs, breaking silos and building bridges.

Data for 2018 shows that acutely ill young people (10-29 year olds) were 30% of acute involuntary admissions. Males and foreign nationals from medium and least developed countries were more frequently represented. Substance abuse, mood disorders and psychotic disorders were the more common diagnostic groups. Building resilience and providing opportunities for early intervention are key elements of better mental health and well-being in the younger generation.

Six examples of good practice in adolescent and youth mental health from Malta will be presented: Youth.inc by AÄ¡enzija Å»gÄ§aÅ¼agÄ§; Kellimni.com by SOS Malta; Youth Mental Health First Aid by Richmond Foundation; Research and Professional Education by ACAMH (Malta); Student Support Services at MCAST MALTA; Project Enlight! by Enlight Foundation. Two of these initiatives were recognised as best practices at European level in a peer learning exercise conducted by the Dutch Youth Institute.

The recommendations are: more focused approaches towards young people with acute mental disorders with special attention to their specific needs; the identification of young people in trouble; work programmes that build resilience, life-skills and employment prospects; the intensified use of refined electronic and social media tools for promotion, prevention and early intervention; and active support and encouragement of peer group development and self-help initiatives.

Key messages:
- Networking stakeholders to break silos and build bridges.
- Resilience and early intervention for better mental health and well-being.

Psychotropic drug purchases among Finnish disability pension applicants with mental disorders

Riku Perhoniemi

R Perhoniemi[1], *J Blomgren*[1], *M Laaksonen*[2], *A Tuulio-Henriksson*[1]
[1]The Social Insurance Institution of Finland, Helsinki, Finland
[2]Finnish Centre for Pensions, Helsinki, Finland
Contact: riku.perhoniemi@kela.fi

Purpose:

Trajectories of psychotropic drug purchases around disability pension process have only been studies among awarded applicants. The aim was to follow and compare psychotropic drug purchases between awarded and rejected applicants before and after the application ruling, and to analyse whether such differences are affected by diagnostic group and sociodemographic background.

Methods:

A representative 70% sample of Finnish adults applying disability pension due to mental or behavioral disorder in 2009-2011 (N = 18,087) were followed for four eight years in three-month periods. Registers of purchased psychotropic drugs measured in defined daily doses (DDDs), gender, age, occupational class, unemployment history, and diagnostic group were used. The DDD levels and trends were analysed using growth curve models.

Results:

The average purchased DDDs of psychotropic drugs increased before the application ruling and decreased gradually thereafter among both awarded and rejected applicants. Before the application ruling the DDD level was higher for the rejected applicants. However, the increase in DDDs was steeper for awarded applicants. The inversed U-curve of purchase amount was most prominent awarded applicants in diagnostic groups of bipolar disorders, depression, anxiety disorders and schizophrenia. The results partly varied between sociodemographic groups.

Conclusions:

The early high level of psychotropic drug purchases of rejected disability pension applicants signals long running ill-health, calling for earlier measures to uphold their functional ability. Respectively, for awarded applicants, the steep DDD increase before the ruling may reflect accurate identification of worsening condition but also access to precise treatment.

Key messages:
- Rejected disability pension applicants with mental disorders suffer from long-running mental ill-health, calling for earlier measures to uphold their mental health and prevent the pension process.
- Awarded disability pension applicants with mental disorders may have access to more precise treatment, but their worsening condition appear to be accurately identified by Finnish system.

The Good Behavior Game: when the classroom becomes the playground for life skills (Toulon area)

Juliette Sondey

J Sondey[1], *N Taurel*[1], *C Khem*[1], *L Negre*[1], *S Birocchi*[1], *C Reynaud-Maurupt*[2]
[1]Comité Départemental d'Education pour la Santé du Var (CODES 83), La Garde, France
[2]Groupe de Recherche sur la Vulnérabilité Sociale (GRVS), Nice, France
Contact: j.sondey@codes83.org

Children presenting disruptive and antisocial behavior are more at risk of developping health and life complications. The "Good Behavior Game" (GBG) is an American classroom behaviour management program implemented by trained teachers. Its effectiveness in public health has been shown by several scientific studies. The program was recently adapted for France by the GRVS, Nice. During 2017-2018, four schools - 1,400 children- benefitted from the GBG program, conducted in the Toulon area by the CODES 83 under the supervision of the GRVS. During their bi-monthly visits to the 29 teachers in training, coaches collected data reports on the past games, and observed a live GBG session. They discussed then with the teacher to build the best classroom management strategy.

Does the GBG help pupils improve their peer relationships? What can the program realistically bring in terms of classroom wellbeing? Those questions are crucial to assess, children's quick benefits, as well as the development of life skills as protective factors for healthy living.

Based on the coaches' observations and feedbacks with the teachers, preliminary results tend to demonstrate that the GBG help pupils improve their peer relationships, notably by evoking cooperation and inclusive behaviors. Pupils present a more positive state-of-mind whether to give a personal opinion, to share speaking time, learn patience, to make collective decisions, to be aware of one's need, to peacefully deal with disagreement, to explain instructions to one another, to ask for another point of view. More active and peaceful approaches to conflict resolution have been noticed. The program seems to enhance wellbeing at class including positive peer interactions and self-appreciation.

Regarding the experiment in the Toulon area, GBG has a strong potential to develop social and life skills of children. GBG seems to work towards better self-esteem, a key lever for peer-pressure resistance and for making healthy choices.

Key messages:

- The ‘‘Good Behavior Game’’ (GBG) creates a positive environment in the classroom, leading children towards positive peer interactions.
- GBG enhances protective factors against peer-pressure an important determinant of risky behavior.

Suicide epidemiology in Italy: a population-based study in Piedmont Region

Giuseppe Costa

C Mamo[1], N Coggiola[1], M Dalmasso[1], A Pitidis[2], G Costa[1]
[1]Epidemiology Unit, Local Health Unit TO3, Piedmont Region, Grugliasco (Torino), Italy
[2]Environment and Trauma Unit, Italian National Institute of Health, Rome, Italy
Contact: giuseppe.costa@unito.it

Background:

Among the largest Italian Regions, Piedmont (Northern Italy) is the one with the highest rate of suicide. Aim of the study was to describe intentional self-harm related deaths in Piedmont analyzing trends by gender, age, area of residence, socio-economic level.

Methods:

Observational mortality study of the resident population in Piedmont from 2003 to 2014. Age-standardized rates of suicide (ICD-10: X60-X84) were estimated, by gender, health district of residence, mountain/level ground, and educational level. Suicide methods and places of occurrence by gender and age were inquired.

Results:

In a context of declining injury related mortality, especially for traffic accidents, the regional trend of suicides shows only a slight decrease, becoming the main cause of injury deaths since 2009, equal to 21% of all injury deaths in the studied period. There are no significant trend variations related to the period of economic crisis. The occurrence is higher among men in general and particularly in older people, persons with low educational level and those living in deprived areas. The main suicide method used by women is ‘‘jumping from a high place’’ (36.7%) while the main one for men is ‘‘hanging, strangulation and suffocation’’ (50%). This is globally the most frequent method for all ages. ‘‘Self-poisoning’’ gains importance between 30 and 49 years old. Suicides occur for over half of cases in home.

Conclusions:

Suicides are a public health and social concern. Yet despite its extent, this problem is still not adequately considered in public health prevention programs. Social and geographical gradients highlitght the importance to improve mental health service provision in deprived areas and to enhance public social welfare measures. Further contributions to a deeper understanding of the determinants of self-harm behaviour and suicidal risk can be obtained from health information systems, in particular data from Emergency Departments and multiple causes of deaths records.

Key messages:

- In Italy, suicides are the main cause of injury deaths, without trend variations.
- Occurrence is higher among men, older people, persons with low educational level and those living in deprived areas.

Identifying People with Dementia in Electronic Primary Care Records in the UK

Sujin Kang

S Kang[1], S Lewis[2], J Gladman[2], V Wardt[2], J Gibson[2]
[1]Department of Surgery and Cancer, Imperial College London, London, UK
[2]Division of Epidemiology and Public Health, University of Nottingham, Nottingham, UK
Contact: skang4@ic.ac.uk

Background:

Many epidemiological questions need to be answered regarding dementia, including the causes, prognosis, comorbidities, and treatment of the condition and complications. A routine electronic primary care dataset provides a way of investigating some of the complicated factors with rich information. However, there has been concern regarding whether dementia is recorded well enough.

Methods:

This study has therefore explored this by conducting a systematic review to understand how dementia has been identified previously in primary care databases in the UK, and added to this by exploring additional terms and symptoms, and medications that might be helpful in identifying people with dementia. The study estimated the prevalence and incidence rates of dementia in The Health Improvement Network (THIN) database and compared with other longitudinal studies using the comprehensive list of diagnostic codes.

Results:

The estimated incidence rates per 1,000 person-years for the 60+ age group who had any of the first diagnosis among the Quality Outcomes Framework (QOF) defined codes, Other diagnoses, Dementia symptoms and Prescribed medications were 2.5, 4.7, and 15.9 in 1995, 2004, and 2015 respectively. The estimated prevalence were 2.8, 3.2, and 10.2 in 1995, 2004, and 2015 respectively.

Conclusions:

The codes related to dementia symptoms (represented by mini-mental state examination, the six item cognitive impairment test, referral to memory clinic and behaviour assessment) seem to cover a broad definition of dementia or pre-existing dementia population in the UK primary care records. At least, using of the Other diagnoses (represented by dementia annual review, senile/presenile dementia and dementia monitoring) in addition to the QOF defined codes, and Prescribed medications were evidenced that will not missing out a number of people with dementia.

Key messages:

- The codes related to dementia symptoms seem to cover a broad definition of dementia or pre-existing dementia population in electronic primary care records in the UK.
- Nevertheless, the codes about non-specific or temporary symptoms may need to be used carefully as it is possible for memory or cognitive function to be impaired temporarily due to other factors.

DR Mental health

Child protection in medicine - closing gaps in continuing education through e-learning

Anna Maier

A Maier[1], U Hoffmann[1], JM Fegert[1]
[1]Department of Child and Adolescent Psychiatry, Psychotherapy, Universityhospital of Ulm, Ulm, Germany
Contact: anna.maier@uniklinik-ulm.de

Background:

Child abuse is a major problem across Europe. The consequences are often serious and long-lasting disorders which, in addition to the individual burden, are extremely costly for the national health system. It is important to prevent or recognize child abuse at an early stage and to provide adequate help to those affected. Health professionals are privileged first contact persons for the victims. However, the WHO assumes that about 90% of cases of child abuse in medical institutions remain unknown. It is therefore important to train health professionals in this field. For this reason, in Germany an E-Learning course on child protection in medicine is currently being developed and evaluated. This article is intended to present the results of the accompanying evaluation of the E-Learning course.

Methods:

The accompanying evaluation collected and analyzed the graduates' opinion on the course, its contents and the topic of child protection in medicine in general. Knowledge and competence levels were surveyed before and after the course and evaluated with a t-test for related samples.

Results:

The evaluation of the course showed a high relevance of the topic of child protection in medicine and the rather low attention paid to the topic in the medical field. The course was, however, assessed very positively and the majority of graduates were already able to apply what they had learnt in their daily work. The pre-post design showed a significant increase in knowledge and skills as a result of the course.

Conclusions:

It turned out that the E-Learning course on child protection in medicine closes an existing gap in the continuing medical education system. The evaluation also shows a success of the program and thus a reduction of uncertainties in child protection procedures among health professionals. A corresponding E-Learning offer for other European countries should be considered in order to address the comprehensive problem of child abuse across the whole of Europe.

Key messages:

- Too little attention is paid to child protection in the medical field.
- E-Learning can effectively train health professionals in child protection, has a wide reach and is flexible in use.

Mental health service use among university students with adverse childhood experiences

Milena Jakovljevic

M Jakovljevic[1], B Matejic[2,3], A Medarevic[4], S Mladenovic Jankovic[1], A Neskovic[1], K Tripkovic[1], G Belamaric[1]
[1]Department of Social Medicine, Institute of Public Health Belgrade, Belgrade, Serbia
[2]Department of Social Medicine, Faculty of Medicine, University of Belgrade, Belgrade, Serbia
[3]Institute of Social Medicine, Belgrade, Serbia
[4]Department of Social Medicine, Institute of Public Health of Serbia, Belgrade, Serbia
Contact: milena.r.jakovljevic@zdravlje.org.rs

Background:

Adverse childhood experiences (ACE) are a risk factor for mental health disorders and serious somatic illnesses. There is a need for preventing ACE and using mental health care by youth who experienced them. Aims of this study were to examine which ACE are related to mental health service use and to identify a scope of unrecognized needs for these services among students who had experienced abuse/neglect in childhood.

Methods:

Descriptive cross-sectional study was performed on a sample of 2.381 first-year students from six universities in Serbia in 2014. The survey instrument was a questionnaire developed by WHO and CDC. Thirteen ACE (covering household dysfunctionalities, abuse, neglect, peer and collective violence) and using of mental health services at least once during lifetime were assessed. Data were analyzed by univariate and multivariate logistic regression.

Results:

Compared to respondents without particular ACE, odds (±95% CI) of mental health service use were higher only in those with next adversities: parental divorce, OR = 2,26 (1,53-3,33); suicidal/mentally ill family member, OR = 2,21 (1,42-3,44); witnessing partner violence, OR = 1,51 (1,04-2,18); peer violence, OR = 2,14 (1,51-3,03); collective violence OR = 1,48 (1,05- 2,10).

Among respondents who had experienced emotional neglect, 81% have never used professional help. For physical neglect, physical and psychological abuse this percentage was 83%.

Conclusions:

The study highlights ACE associated with mental health service use and shows a significant presence of unrecognized needs for these services. There is need for: determining barriers in this area and formulation of effective health promotion strategies; more consistent application of legislation; conducting screening on child abuse/neglect in families with a higher risk for them.

Key messages:

- High share of youth with childhood adversities remains without help of mental health specialists.It opens the issue of barriers on the side of youth as well as on the side of health system and society
- Considering consequences of adverse childhood experiences, there is need for comprehensive public health interventions in order to increase mental health service use among young people with ACE.

Early recognition of mental health problems in Croatia.

Danijela Stimac

D Stimac[1,2], I Pavic Simetin[1], A Istvanovic[1]
[1]Department for Mental Health and Addiction Prevention, Croatian Public Health Association, Zagreb, Croatia
[2]School of Medicine, University of Zagreb, Zagreb, Croatia
Contact: danijela.stimac@hzjz.hr

Issue/problem:

Mental disorders account for the largest and fastest growing categories of the burden of disease in Croatia. Around 30% of the population has experienced some form of mental illness in the past year. 32% of them had more than one mental health problem. 50% of mental disorders arise by the age of 14. School medical doctors in Croatia are in the position to do early recognition of mental disorders during regular check-ups of school children. It is very important that the health care system helps people to be aware of early signs of mental health problems and enable people to get the timely treatment. According to those facts, Croatian Institute of Public Health starts the preparation for implementing screening for mental health risks of school children. The screening will be implemented by the school medical teams for all students as part of regular yearly check-ups in the 5th and 8th grade of elementary school and 1st grade of secondary school. The screening will be carried out using the YP-CORE questionnaire, which measures the degree of general mental distress. Students at increased risk will be referred to Mental Health Departments in County Public Health Institutes. Mental Health Department's team of experts, which includes psychiatrist, nurse and psychologist, will carry out further diagnostic and treatment. Education of school staff, which includes teachers, school psychologists, special educators, social workers, nurses who are in direct contact with the children will also take place. Parents also should be educated on early recognition of mental disorders and should be recognized as partners in diagnostics and therapy throughout the child's life.

Lessons:

Early recognition of mental disorders leads to a reduction of psychological distress and increased feelings of control over one's health.

Key messages:

- Early recognition of mental disorders leads to a reduction of psychological distress and increased feelings of control over one's health.
- School staff and parents should be partners in earliy recognition and treatment of mental disorders of school childrens.

Policies for psychiatric rehabilitation: inclusion through planning permit legislation changes

Evangelia Chrysikou

E Chrysikou[1,2], E Savvopoulou[3]
[1]Bartlett UCL, the Bartlett Real Estate Institute UCL, London, UK

Contact: e.chrysikou@ucl.ac.uk

Issue:

Mental illness increases. Europe has the highest suicide rates. Yet, psychiatric provision is stull pushed towards the fringes even in new small-scale structures. This, contradicts Social Psychiatry, ignores WHO directions and undermines European health and equity.

Description of the problem:

Changing mental health facilities planning legislation could support integration. Using Greece as a case study, we examine how mental health planning and licensing legislation affected national integration outcomes. This was policy, time-intensive project to address gaps remaining at the end of Psychargos-the national de-institutionalisation programme. It revisited the licensing of facilities to prevent the Greek psychiatric population from facing homelessness with Psychargo's closure. The research identified solutions for the licensing of psychiatric service provision. Most of the remaining issues related to planning permits. Methodology included literature review, site-visits, consultations with Psychargos leadership and a detailed questionnaire designed by the researchers distributed via email to all facilities of Greece. 112 out of 116 of all community based facilities chose to participate.

Results:

We identified the country's planning legislation as important contributor to exclusion. The uses of land prevented facilities from being located in neighborhoods and promoted the development of mental health accommodation in industrial-type buildings or segregated areas. Uses needed relaxing for mental health. This generated functional complications. It necessitated the introduction of new national design guidelines.

Lessons:

This project shed light on a model of de-institutionalisation that has already been applied in a European country with limited resources. It could have great value to countries starting de-institutionalisation. It could be relevant to the most advanced countries such as the UK, as several of their 'community-based wards' are still in hospital campi.

Key messages:

- Buildings affect psychiatric de-institutionalisation (types, location, layout and equipment). De-institutionalisation buildings might undermine re-integration. National provision(s) need revisiting.
- Special use creates difficulties for mental health facilities to be located close to where people leave. Enabling flexibility in the choice of buildings promotes inclusion.

The social invisibility of mental health: understanding social exclusion through place & space

Evangelia Chrysikou

E Chrysikou[1,2], E Savvopoulou[3], E Kostopoulou[4], N Mukadam[5], I Tsimopoulou[6], S Pickering[7], A Fatah gen. Schieck[4]
[1]Bartlett UCL, the Bartlett Real Estate Institute UCL, London, UK
[2]University of Crete, Medical School, Crete, Greece
[3]SynThesis Architects, Athens, Greece
[4]Bartlett UCL, The Bartlett School of Architecture, London, UK
[5]UCL, Division of Psychiatry, London, UK
[6]Camden and Islington NHS Foundation Trust, London, UK
[7]UCL, Slade School of Fine Art, London, UK
Contact: e.chrysikou@ucl.ac.uk

Background:

The European target that the 5% of the healthcare service budget goes to mental health might not be enough to cover the inequity between health and mental health provision. The project is a multi-disciplinary, research-through-arts project, involving a Faculty of the Built Environment, a Division of Psychiatry and a School of Art. The project aims to identify elements demonstrating inequality demonstrated from place and space related to the facility provision.

Methods:

The research compares mental vs healthcare facilities inside a catchment area, with photographs of the facades of the buildings and mapping their proximity to public transportation. It juxtaposes mental/healthcare facilities for access, condition and status compared to their surroundings.

Results:

A book and an exhibition close to Bentham's auto-icon, the designer of Panopticon custodial facility, demonstrated inverse links between his Panopticon, and the invisibility that NIMBYism produces towards the mentally ill that resulted in their exclusion, within deprived, vandalized, under-funded, isolated from public transport facilities ''in the community''.

Conclusions:

The project identified factors that contribute to the isolation of mental health facilities in terms of both space and place, and set the basis for further research in future projects. It demonstrated visually the under-budgeting of mental health facilities and their stigmatization as expressed by the centrality of locations and their overall projected image. This outlined the path for integrated, transdisciplinary research in the future involving architecture, arts and psychiatry. The project increased the awareness of the general public on social injustice, stigma and mental health. It combats NIMBYism and supports the fairer allocation of resources and placement of health facilities, aiming to put pressure to stakeholders involved in the NHS decision. Actions have been taken by the Trust involved to change.

Key messages:

- Inequalities between building (facades and location) contribute to mental illness stigma: this is what the general public views daily.
- Architecture can be a powerful medium to support inclusion.

Evaluation of Cyber Bullying and Self-Esteem in High School Students

Sevil Aydoğan

S Aydoğan[1], A Ünsal[1], D Arslantaş[1], E Atay[1], G Öztürk Emiral[1]
[1]Department of Public Health, Eskişehir Osmangazi University Medicine Faculty, Eskişehir, Turkey
Contact: aydogan.sevil@gmail.com

Background:

Cyber bullying (CB) is a repetitive use of information and communication technologies to harm other individuals. In recent years, CB has become more common among adolescents with the increase in availability of technological devices and technological developments. CB may harm the emotional, social and psychological development of the individuals of developmental age and social relations. CB is reported to be higher in people with low self-esteem. The aim of this study is to determine the frequency of CB among high school students, to examine some variables which may be related and to evaluate self-esteem.

Methods:

This is a cross-sectional study conducted between 1 May-30 June 2018 among high school students in Sivrihisar. The study group consisted of 712 students which 60.1% were female, 39.9% were male and the mean of ages was 16.3±1.2 years (ranged 13-20). CB was evaluated with 2nd Revision of the Revised Cyber Bullying Inventory (RCBI-II) and self-esteem was evaluated with Rosenberg Self-Esteem Scale (RSES). Chi-square, logistic regression and Spearman correlation analyses were used to analyze the data.

Results:

The frequency of CB was 57.6% (n = 410). The frequency of CB was higher in men (OR:1.45,CI:1.01-2.1), the group who accept the friendship request of the people they don't know in the virtual environment (OR:1.84,CI:1.22-2.78), who had problems with anyone on internet (OR:2.27,CI:1.54-3.35), who tells about something that can't speak in real life (OR:2.13, CI:1.48-3.06), who share the problem orginated from online communication with anyone around (OR:1.48, CI:1.03-2.15). There was a positive weak correlation between the scores of the RCBI-II and RSES.

Conclusions:

CB is a common problem among high school students. There is a weak negative relationship between the level of CB and self-esteem. It may be useful to increase the awareness of students, parents and teachers on the subject and to provide psychological support to students to reduce the level of CB.

Key messages:

- It is remarkable that the self-esteem of cyber-bullies is low.
- Risky behavior on the internet is an important risk factor for cyber bullying.

Reflective citizens as a tool for well-being and public health achievement (Novi Sad, Serbia)

Marija Jevtic

M Jevtic[1,2]*, I Flasar*[2]*, M Mojovic*[2]
[1]Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia
[2]Psycho-Social Section, Group Analytic Society-Belgrade, Belgrade, Serbia
Contact: marija.jevtic@uns.ac.rs

Issue/Description:

Reflective Citizens (RC) as 'psycho-social transitional spaces' - were established in 2005, when Serbia joined the International Listening Posts (LP) Network of OPUS (Organization for Promoting Understanding of Society). Recognizing the need for more reflective citizens' spaces, for continuously ongoing work through social trauma, Psycho-Social section (PSS - GAS Belgrade) began organizing them more often and in different cities. Serbian RC developed specific conceptualization and methodology, carefully integrating aspects of LP, group analysis, group's relations, and social dreaming, which are still in the process of evaluation and improvement.

Results:

RC in Novi Sad have started in 2014, with a huge enthusiasm, as a team work of PSS. It is recognized that Novi Sad, as a multinational and specific multicultural environment could develop Applied Reflective Citizens - Citizens' dialogue in cultural spaces in Novi Sad, as supportive and open space for all citizens who wish to develop themselves, multiculturalism, tolerance and better social environment. At the seven workshops organized by now, the beginning was marked by a session of social dreaming. Free psychosocial associations in thinkrooms have defined the topics: loneliness, helplessness, walls and borders, migrations, diversity, mental malnutrition, the presence of evil and the need for goodness, lack of communication... and on the basis of them, the corresponding hypotheses.

Lessons:

Applied Reflective Citizens have become the support and open space for all citizens who want to contribute to multiculturalism, tolerance, a better social environment, understanding the environment and building incentive bridges in communication through dialogue and also to contribute to a positive cultural climate, building cultural capacities and fostering cultural dialogue through mutual reflection, thus contributing the quality of life, which is of public health significance.

Key messages:

- Reflective Citizens can be a contribution for improving health in community through fostering dialogue and mutual reflection.
- Reflective Citizens give an open space for all citizens who want to contribute to multiculturalism, tolerance, better social environment, thus contributing quality of life, and to public health, also.

The impact of participation in support groups on mental health of parents having children with autism

Arnur Gusmanov

R Alibekova[1]*, K Kadyrzhanuly*[1]*, C K Chan*[2]*, S An*[3]*, A Gusmanov*[4]*, Z Yerubayev*[4]*, F Yessimkulova*[4]*, A Bekisheva*[4]*, Z Ospanova*[4]*, M Rakhimova*[4]
[1]Department of Medicine, School of Medicine, Nazarbayev University, Nursultan, Kazakhstan
[2]Department of Biomedical Sciences, Nazarbayev University, Nursultan, Kazakhstan
[3]School of Humanities and Social Sciencies, Nazarbayev University, Nursultan, Kazakhstan
[4]Master of Public Health Program, School of Medicine, Nazarbayev University, Nursultan, Kazakhstan
Contact: arnur.gusmanov@nu.edu.kz

Introduction:

Whilst there is accumulated evidence about the high prevalence of stress and mood disorders in parents of children with autism, few studies have shown that participating in parental support groups was associated with less mental health problems. This study was aimed to explore the association of participation in support groups with stress and mood disorders in parents of children with autism in Kazakhstan.

Methods:

Participants (n = 146) were recruited to this cross-sectional survey from autism non-governmental organizations and Republican Children's Rehabilitation Center in Nur-Sultan city during April-December 2018. A 59 item survey consisted of questions on parental socio-demographics, needs, participation in support groups, depression, anxiety and stress (DASS), and Multidimensional Scale of Perceived Social Support (MSPSS). Descriptive, bivariate and multivariate logistic regression analyses were performed in STATA 15.

Results:

44.4% of parents reported experiencing stress, and almost half of the sample had elevated depressive (53.7%) and anxiety symptoms (47.4%). 45.3% of participants were members of parental organizations; there were no significant differences in the prevalence of stress and mood disorders among members and non-members of parental support groups. Results of the multivariate logistic regression showed that parents with older autistic children (OR 1.37, p-value 0.001), less family support (OR 0.894, p-value 0.044) and higher income (OR 3.01, p-value 0.025) were more likely to be members of support groups.

Conclusions:

These findings indicate the need to increase support groups to under-served populations of Kazakhstan's families with autistic children. Additional efforts are needed to strengthen the role of support groups in meeting the emotional needs of the parents.

Key messages:

- Parents of children with autism spectrum disorder experience elevated level of stress and mood disorders; however

participation in support groups was not beneficial for relieving parental distress.
- Further research is warranted to explore the benefits of participation in support groups, and interventions are needed to strengthen the role of support groups in meeting the needs of parents.

Verbal victimisation and mental health of sexual minority adults in France

Fabienne El-Khoury

F El-Khoury[1], *K Marr*[1], *M Melchior*[1], *M Héron*[1], *Equipe Baromètre Santé 2017*[2]
[1]INSERM UMRS 1136,Institut Pierre Louis d'Epidémiologie et de Santé Publique, Paris, France
[2]Santé Publique France, Saint-Maurice, France
Contact: fabienne.khoury@gmail.com

Objectives:

Sexual minority individuals face minority stress, and specific discrimination and abuse that might increase their risk of having mental health problems. We examine associations between sexual orientation, experienced violence in the past year, and mental health outcomes in a representative sample of French adults aged 18 to 75 years.

Methods:

Analyses were based on the ''Health Barometer'' (Baromètre Santé) a nationally representative, cross-sectional survey which recruited 25,198 adults in 2017. Data were weighted to be representative of the French adult population. Four mental health outcomes occurring in the preceding year or currently were examined: a) current depressive symptoms, b) having experienced a major depressive episode, c) suicidal ideation, and d) suicide attempt. We conducted mediation analysis using the counterfactual approach to evaluate the contribution that verbal violence victimisation experience in the preceding year has in the association between sexual orientation and mental health outcomes.

Results:

Sexual minority adults were more likely to experience verbal violence in the last year compared to heterosexual individuals (22% vs 11.4%). They were also more likely to have experienced each of the four mental health outcomes. Verbal victimisation in the preceding was found to significantly mediate the association between sexual orientation and mental health outcome with mediated proportions varying between 15 to 22%.

Discussion:

Initiatives that aim to structurally reduce stigma and victimisation against sexual minority individuals, but also improve social support and resilience, could have a significant impact on their mental health and well-being.

Key messages:

- Sexual minority adults are more likely to experience verbal violence, and mental health problems.
- Verbal victimisation partly explains the increased risk of having mental health problems among sexual minority individuals.

Sexual violence and suicidal ideation among French adults, a mediation analysis

Fabienne El-Khoury

F El-Khoury[1], *Equipe Baromètre Santé 2017*[2]
[1]INSERM UMRS 1136, Institut Pierre Louis d'Epidémiologie et de Santé Publique, Paris, France
[2]Santé Publique France, Saint-Maurice, France
Contact: fabienne.khoury@gmail.com

Objectives:

Sexual violence against women is endemic and is linked with a host of mental health problems and suicidal behaviour. We test whether sexual violence is more prevalent and have more damaging psychological effects among women compared to men, and quantify its mediating role in the association between sex and suicidal ideation and behaviour.

Methods:

We used data from the ''Health Barometer'' (Baromètre Santé) 2017 a cross-sectional phone survey, which recruited a nationally representative sample of French adults aged 18 to 75 years in 2017 (n = 25319). Data were weighted to be representative of the French adult population. Outcomes included suicidal ideation, imagery of suicide, and suicide attempts in the preceding year. We conducted mutlivariable mediation analysis using the counterfactual approach to evaluate the contribution that lifetime sexual violence has in the association between sex and suicidal ideation and behaviour.

Results:

We found that women are five times more likely to have experienced sexual victimisation, and are more at risk of any suicidal ideation and imagery of suicide in the preceding year compared to men. Women and men had comparable rates of suicide attempts in the preceding year.

We estimated that 47% of the increased risk of suicidal ideation in the preceding year women have compared to men is mediated by lifetime sexual assault. Lifetime sexual assault also explained 39% of the association between sex and having imagery of suicide.

Discussion:

Our findings reiterate the importance of the prevention of sexual violence and an adequate care for sexual assault victims, especially women, in public health and mental health policies and initiatives.

Key messages:

- Women are five times more likely to have experienced sexual victimisation compared to men, and are more likely to suffer from suicidal ideation in the preceding year.
- Experience of lifetime sexual violence contributes substantially (around 50%) to women's increased likelihood of suicidal ideation compared to men.

The EMMY Project: Promoting mental wellbeing among the oldest old – The Finnish Case

Anna Forsman

AK Forsman[1], *J Nordmyr*[1]
[1]Faculty of Education and Welfare Studies, Health Sciences, Åbo Akademi University, Vaasa, Finland
Contact: anna.k.forsman@abo.fi

Background:

The European Welfare Models and Mental Wellbeing in Final Years of Life (EMMY, 2017-19) project covers interdisciplinary and mixed method studies on mental wellbeing among the oldest old in Finland, Italy, Norway and Spain. The overarching aim is to strengthen the understanding of how welfare models and related policies could be adapted to support mental wellbeing in the oldest old. Project results will be incorporated in a new tool for assessing the mental wellbeing impact of welfare policies.

Methods:

23 focus group interviews were conducted, including 117 participants aged 80 years or older. Six of these were conducted in Finland (N = 28) and the data was analysed using qualitative content analysis. In a policy analysis, relevant national legislation, plans and programmes were identified from the four countries. Five key stakeholders in each country validated the identified policies in interviews. The policy items were systematically coded (N = 42 in Finland), focusing on their correspondence with older adults' own views on their mental wellbeing and its protective factors.

Results:

The findings highlight that although functional status undeniably plays an important role for experienced wellbeing in general, it is not the principal component of the experienced mental wellbeing among the oldest-old. The Finnish policy case pinpoints both promising policy examples, but also development needs such as the inclusion of issues related to e.g. digitalization and social challenges including loneliness.

Conclusions:

These findings have significant multi-level implications, showcasing the importance of coordinated actions at societal and individual levels alike. Actions to enhance social participation, especially for individuals with reduced social networks are needed, as well as a more holistic approach in general considering the multi-dimensional nature of experienced mental wellbeing in later life.

Key messages:

- Results support the exchange of good policies between EU Member States to incorporate a change of focus from mental disorders to mental wellbeing among older people and its protective factors.
- Country-specific case studies highlight the relevance of context,pinpointing the various pathways to increased mental wellbeing that could be translated into policy.

Assessment of Cognitive Reserve: a pilot study for Bulgarian Population

Antonya Yaneva

A Yaneva[1], R Massaldjieva[2], N Mateva[1], D Bakova[2]
[1]Medical Informatics, Biostatistics and e-Learning, Faculty of Public Health, Medical University of Plovdiv, Plovdiv, Bulgaria
[2]Health Care Management, Faculty of Public Health, Medical University of Plovdiv, Plovdiv, Bulgaria
Contact: yaneva.antonya@gmail.com

Background:

The Cognitive Reserve (CR) is a concept used to represent the individual differences in processing cognitive tasks, allowing to cope with the pathology of the brain. CR describes the individual brain potential as a result of various activities during the lifespan. The study of this construct could open one more "door" on the path to the prevention of diseases associated with cognitive dysfunctions in human aging. The objective of this pilot study was to assess the CR as a part of a project aimed to evaluate the effectiveness of various options for stimulating active aging.

Methods:

The Cognitive Reserve Index Questionnaire (CRIq) was translated into Bulgarian and was administered to 114 healthy participants (84,2% female and 15,8% male), aged 23 to 84 years (M = 52,40 SD = 16.81), divided into three age groups (up to 44, 45- 69 and over 70 years old). An individual CRI-level was calculated based on the subscores for education, working activity and leisure time. Non-parametric tests (Chi-square, Mann-Whitney U-test, and Kruskal-Wallis test) were used for statistical analysis.

Findings:

The CRI-level depends significantly on age ($\chi^2 = 31.834$, (df = 6), $p < 0.001$) but does not depend on gender ($p = 0.257$). Significant difference was found in three age groups for the total CRI-score ($p < 0.001$), CRI-Education ($p < 0.001$) and CRI-WorkingActivity ($p < 0.001$) except for CRI-LeisureTime score ($p = 0.547$). The total CRI-score significantly correlate with CRI-Education ($r = 0.863$), CRI-WorkingActivity ($r = 0.809$) and CRI-LeasureTime ($r = 0.414$).

Key messages:

- The CRIq is an easy to administer instrument that could help the assessment of the cognitive reserve in Bulgarian population.
- The cognitive reserve depends on human behavior through the life span and this fact gives new opportunities for prevention of diseases associated with cognitive dysfunctions in human aging.

Psychosocial distress and cardiovascular disease

Yvonne Natt och Dag

Y Natt och Dag[1], K Mehlig[1], A Rosengren[2], L Lissner[1], M Rosvall[1]
[1]Department of Public Health and Community Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden
[2]Department of Molecular and Clinical Medicine, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden
Contact: yvonne.nattochdag@gu.se

Background:

The contemporary increase in psychological distress observed in many countries is, by itself, a public health issue of great concern.

Methods:

This prospective study aims to investigate the impact of psychological distress on incident cardiovascular disease, in different age groups and also with respect to sex, among participants in the Gothenburg-based InterGene Study cohort. This cohort comprises a total of 3614 men and women, aged 25-75 years. Included in the present study were individuals who were free of previous CVD diagnoses and who fully completed all baseline examinations. Inclusions took place during 2001-2004. Psychological distress at baseline was assessed by self-rating depression and anxiety scales. A wide range of physiological and behavioral parameters were also assessed, which allowed for relevant adjustments. The outcome was incident CVD, and with a 12 year follow-up. Cox-regression analyses were performed.

Results:

The results showed an increased risk of incident CVD with higher scores on each of the scales. The majority of the findings persisted after adjustments for relevant confounders. It was most common for young women to score high on the anxiety and depression scales.

Conclusions:

The associations between psychological distress and later life cardiovascular disease calls for enhanced public health measures aiming at ameliorating psychological health, not least in younger age groups.

Key messages:

- There was an increased risk of incident CVD with higher scores on psychosocial distress scales.
- The majority of the findings persisted after adjustments for relevant confounders.

Evaluation of Social Media Use Disorder in Medical Faculty Students

Hatice Aygar

H Aygar[1], A Unsal[1], D Arslantas[1], B Isıktekin Atalay[1], C Cam[1], A Kılınc[1], S Akbulut Zencirci[1], B Durak Aras[2]
[1]Department of Public Health, Eskisehir Osmangazi University Medicine Faculty, Eskisehir, Turkey
[2]Department of Medical Genetics, Eskisehir Osmangazi University Medicine Faculty, Eskisehir, Turkey
Contact: haticeaygar1990@gmail.com

Background:

Recently, social media usage disorder has become a behavioral addiction with the internet which has entered our daily life rapidly. One of the important factors considered to be associated with social media use disorder is thought to be loneliness. The aim of the study was to evaluate the social media use disorder in medical school students.

Methods:

This study is a cross-sectional study conducted on the students who were studying in Eskisehir Osmangazi University Faculty of Medicine between January 2 and February 28, 2019. The study group consisted of 422 internet user students. The level of social media usage was assessed by Social Media Disorder Scale (SMD-scale). The level of loneliness was evaluated with the short-form of the UCLA Loneliness Scale (ULS-8). Mann Whitney U, Kruskal Wallis, Spearman correlation analysis were used.

Results:

Of the participants 226 (53.6%) was male. The age of the study group ranged from 17 to 29 years and the mean (SD) was 19.78 (1.33) years. The scores obtained from SMD-scale ranged from 0 to 63, with a mean of 12.18±10.35 (median = 9.0). All students had at least one social media account. In the study, no difference was found between the scores obtained from gender, age group, father's education status, family income status and family type. While the scores of the students whose mothers have a university education level are lower; those who spent more than 2 hours a day on social media had a higher score. There was a weak positive correlation between the scores obtained from SMD-scale and ULS-8 ($p < 0.001$, $r = 0.215$). There was a weak negative correlation between the scores obtained from the SMD-scale and the academic grade point average ($p = 0.012$, $r = -0.123$).

Conclusions:

It is concluded that the correct use of social media can be increased by informing about this issue. Increasing platforms such as student clubs in which individuals could socialize in real life may be useful in reducing this disorder.

Key messages:

- Public health studies could help prevent social media use disorder transform into more serious health problem in future.
- Further studies are needed to determine the effects of social media use disorders on mental and physical health.

Interventions to reduce stress, anxiety and depression symptoms in teenagers – a systematic review

Silvia Florescu

S Florescu[1,2], C Mihaescu Pintia[1,2], M Ciutan[1,2], C Sasu[1,2], R Sfetcu[3], SG Scintee[1,2], C Vladescu[1,2]
[1]NSPHMPD, National School of Public Health, Management and Professional Development, Bucharest, Romania
[2]PHEBRC_JBI_AG_R, Public Health Evidence Based Romanian
Centre: A Joanna Briggs Institute Affiliated Group Romania, Bucharest, Romania
[3]Spiru Haret University, Faculty of Psychology and Educational Sciences, Bucharest, Romania
Contact: florescu.silvia@gmail.com

Introduction:

Stress, anxiety and depression symptoms are frequent in teenagers. Objectives: To identify the interventions effectively able to prevent or reduce anxiety, depression and psychological stress in adolescents; to assess the effectiveness, feasibility and transferability of the interventions.

Methods:

Comprehensive systematic review was performed. Three steps searching strategy using the databases: PsycINFO, PubMed, SCOPUS, Cochrane Library, and Google Scholar identified 679 studies and reviews. Critical appraisal was performed by 2 reviewers, data extraction performed on finally selected 59 reviews, RCT, cohort studies focused on sample size, geographical context, setting, description of intervention, measures of primary and secondary outcomes.

Results:

The considered interventions are: Internet-based multifaceted cognitive bias modification training (CBM), Internet (iCBT) or school-based cognitive behavioral group training (CBT), Social skills training (SST), Metacognitive therapy, Psychosocial Support Intervention, organized sports participation and voluntary outdoor play, school-based resilience-focused intervention, assertiveness group training, short-term psychoanalytic psychotherapy (STPP), brief psychosocial intervention (BPI), Guided Parent-Delivered Cognitive Behaviour Therapy (GPD-CBT), Internet-based self-support method.

Conclusions:

Interventions for promoting mental health in adolescents have to combine parenting programs with leisure activities and balanced curriculum; various approaches (physical activity, music, sports participation) should be tailored into the national, community and school contexts. Resilience factors (relationship with parents, communications with peers), development of help-seeking behaviours and available self-help programs could support early detection and assistance. Most interventions showed positive effects on short and medium term and potential transferability.

Key messages:

- Regular screening for childhood adversities and traumas and screening of symptoms as feeling sad, hopeless, worried should be performed in adolescents as they get older.
- Besides mental health risk factors, interventions should target developmental risk factors in transitional stages from childhood to adolescence and from adolescence to young adulthood.

The neighborhood age structure and mental health

Joost Oude Groeniger

E Verspoor[1], MA Beenackers[1], J Ouder Groeniger[1,2], JM Noordzij[1], FJ Van Lenthe[1,3]
[1]Public Health, Erasmus University Medical Center, Rotterdam, Netherlands
[2]Public Administration and Sociology, Erasmus University, Rotterdam, Netherlands
[3]Human Geography and Spatial Planning, Utrecht University, Utrecht, Netherlands
Contact: j.oudegroeniger@erasmusmc.nl

Background:

Against the background of urbanization and aging and the aim to design age-friendly cities, it is crucially important to understand whether and why older adults' health may benefit from being surrounded by older peers mainly, or by residents from all ages. We assessed the association between neighborhood age structure and mental health and the mediating role of social neighborhood perceptions.

Methods:

Survey data were obtained from 1255 older adults aged 65 years and over, participating in the Dutch GLOBE study. The neighborhood age structure, measured in 2011, was defined as the Herfindahl-Hirschman index to assess homogeneity in the age composition (range from 0-100, a higher score indicating more homogeneity) and percentages of different age groups in a neighborhood. Mental health was measured in 2014 by the Mental Health Inventory-5 score, ranging from 0 to 100, where a higher score indicates better mental health. Perceptions of neighborhood social cohesion, feeling at home in a neighborhood, and social participation was assessed in 2011. Linear regression models were used to assess the association of neighborhood age composition with mental health. Causal mediation analysis was used to assess the potential mediating role of social neighborhood perceptions.

Results:

A more homogeneous neighborhood age structure was associated with better mental health status. Feeling at home in a neighborhood partly mediated the association, whereas social cohesion and social participation did not mediate the association. While a higher percentage of children in the neighborhood was associated with better mental health, a higher percentage of elderly in the neighborhood was associated with lower mental health status.

Conclusions:

The neighborhood age composition is a promising, but currently insufficiently understood, entry point for policies addressing the challenge of growing urban and aging European cities.

Key messages:

- The neighborhood age composition is a promising, but currently insufficiently understood, entry point for policies addressing the challenge of growing urban and aging European cities.
- Feeling at home in a neighborhood partly mediated the association between neighborhood age structure and mental health; social cohesion and social participation did not mediate the association.

The impact of the economic crisis on the mental health of Portuguese primary-school children

Diogo Costa

D Costa[1], M Cunha[1], C Ferreira[1], A Gama[1,2], AMN Rodrigues[1,3], V Rosado-Marques[1,2], H Nogueira[1], MRG Silva[1,4], C Padez[1]

[1]University of Coimbra, Coimbra, Portugal
[2]University of Lisbon, Lisbon, Portugal
[3]Polytechnic Institute of Viseu, Viseu, Portugal
[4]Fernando Pessoa University, Porto, Portugal
Contact: diogo.costa@uc.pt

Objective:

To measure the impact of the economic crisis on the mental health correlates of Portuguese children attending primary school during 2016.

Methods:

Cross-sectional analysis of primary school-aged children and their parents ($n = 1157$), conducted in public and private schools of three Portuguese districts. Parent reports of children mental health symptoms (Strengths and Difficulties Questionnaire - SDQ) and children self-reports of health-related quality of life (KIDSCREEN-27) and depressive, anxiety and stress symptoms (Depression, Anxiety and Stress Scales, Children version - DASS-C), were compared according to a set of yes/no questions on how the economic crisis changed the normal aspects of routine life (e.g. During the financial crisis did you had to use savings? Started buying cheaper food?). Linear regression models were fitted for the SDQ, the KIDSCREEN-27 and the DASS-C as dependent variables adjusted for children sex, socioeconomic status and district of residence.

Results:

Affirmative answers to the crisis impact questions were associated with more frequent psychosocial functioning problems in children, with poorer self-reported health-related quality of life and with more frequent symptoms of depression, anxiety and stress.

Conclusions:

Portuguese children mental health correlates show significant worse scores for those whose parents declared having to change daily routine habits as a result of the recent macroeconomic financial crisis, compared to those who did not change habits. Public Health programs should be developed to mitigate the potential negative impact of the financial crisis to the mental health of children.

Key messages:

- A negative impact on children mental health was observed as a result of the economic crisis.
- Public health programs designed to mitigate the impact of the economic crisis should include primary-school aged children.

Association among defense mechanisms, causes of procrastination and well- being; Gender differences

Thomas Tsiampalis

P Vlachopanou[2], E Karagiannopoulou[2], T Tsiampalis[1]
[1]Institute of Preventive Medicine, Environmental & Occupational Health, Amarousion, Greece
[2]Philosophy Pedagogy Psychology section of Psychology, University of Ioannina, Ioannina, Greece
Contact: t.tsiampalis@prolepsis.gr

Background:

Defense mechanisms have been a central concept in the field of mental health and psychotherapy. Recently, there has been some research interest in defence mechanisms in empirical psychology. Causes of procrastination are shown to be related to defence mechanisms in terms of students' dilatory behaviour. Furthermore, the causes of procrastination seem to affect students' well-being. The aim of the present study is to investigate the effect of defence mechanisms and causes of procrastination on well-being, separately for each gender.

Methods:

A cross-sectional study was conducted in Greece with 628 college students at the University of Ioannina (490 females and 138 males). Specially designed and validated instruments were used to record students' sociodemographic characteristics, defence mechanisms (DM), causes of procrastination (CP) and well-being (WB). Analysis of Variance (ANOVA) and Covariance (ANCOVA) was used to investigate the effect of DM and CP on students' WB separately for each gender.

Results:

Students' defence mechanisms and causes of procrastination had a statistically significant effect on their well-being. More specifically, female students with a lower percentage of fear of success/ influence of peers ($p < 0.001$) and maladaptive defense style ($p < 0.001$) as well as those with higher image-distorting ($p < 0.001$), self-sacrificing ($p = 0.004$) and adaptive defense styles ($p < 0.001$) seemed to have a significantly higher percentage of well-being. On the other hand, male students with a lower percentage of lack of duty/ tolerance of frustration ($p = 0.039$) and maladaptive style ($p < 0.001$) but a higher percentage of image distorting ($p < 0.001$) and adaptive defence styles ($p < 0.001$) had a significantly higher percentage of well-being.

Conclusions:

Students' causes of academic procrastination in the combination with the use of defence mechanisms significantly affect their well-being despite, being differentiated according to their gender.

Key messages:

- Defense mechanisms play a crucial role in students' adaptation at the university as well as in their mental health.
- Emphasis should be given on the design of intervention on students' procrastination involving non-conscious processes and more structural elements of personality.

Effectiveness of the Children of Divorce Intervention Program in the Netherlands

Mariska Klein Velderman

M Klein Velderman[1], P van Dommelen[1], FD Pannebakker[1], SA Reijneveld[1,2]
[1]Child Health, TNO, Leiden, Netherlands
[2]Department of Health Sciences, University Medical Center Groningen, Groningen, Netherlands
Contact: mariska.kleinvelderman@tno.nl

Background:

Many children experience parental separation and divorce. This experience is likely to negatively affect their wellbeing, conduct, psychological adjustment and social relations. Prevention of these problems thus has major priority but effective intervention programmes are still rare. This study therefore aimed to assess the effects of a 12-session preventive group intervention "Dappere Dinos^{TM}" for 6 to 8 year old children.

Methods:

We performed a quasi-experimental study (registered as NTR 6788) on 105 children participating in the intervention group, 37 children with separated parents not participating ('divorce controls') and 138 children from intact families ('intact controls'). Outcomes regarded children's positive functioning (Parent Evaluation Form; Pedro-Carroll & Cowen, 1989), emotional and behavioral problems (Strengths and Difficulties Questionnaire; Goodman, 1997), and wellbeing (Cantril ladder, Cantril, 1965).

Results:

Analyses showed that children's positive functioning after participating in Dappere Dino's increased according to mothers (MΔpre-post(SD) = 0.26 (0.32); $p < .001$). Also, children's overall emotional and behavioral problems decreased after participation (MΔpre-post_mother(SD) = -2.02 (4.55); $p < .01$; MΔpre-post_trainer(SD) = -1.07 (4.34); $p < .05$; MΔpre-post_teacher(SD) = -1.64 (3.54); $p < .01$). Children's wellbeing increased after participation (MΔpre-post_mother(SD) = 0.77 (1.02); $p < .001$; MΔpre-post_trainer(SD) = 0.69 (0.94); $p < .001$), or stayed the same (MΔpre-post_teacher(SD) = 0.19 (1.03); p = n.s.). No such changes were found in the two comparison groups.

Conclusions:

After parental divorce, a 12-session preventive group intervention Dappere Dino's^{TM} for 6- to 8-year-olds can be efficacious in promoting children's emotional well-being and positive functioning, and reducing their emotional and behavioral problems.

Key messages:

- Given the high prevalence of divorce and the potential risk for child well-being and functioning, prevention of problems for these children and helping them adapt to the divorce are major priorities.
- After parental divorce, preventive group support can be efficacious in promoting children's emotional well-being and positive functioning, and reducing their emotional and behavioral problems.

Socioeconomic differences in the adolescent mental health time trend: what do we refer to?

Yunhwan Kim

Y Kim[1], BE Evans[1], D Bergh[1], C Hagquist[1]
[1]Centre for Research on Child and Adolescent Mental Health, Karlstad University, Karlstad, Sweden
Contact: yunhwan.kim@kau.se

Background:

The long-term increase in adolescent internalizing mental health problems in many countries has raised the question of potential socioeconomic status (SES) differences in this trend. Inconsistencies in how SES and mental health are operationalized hamper this question to be addressed. We examined variation in the adolescent mental health trend across different SES groups using different ways of operationalizing SES and mental health.

Methods:

We used six waves (1993-2013) of Swedish data from the Health Behaviour of School-aged Children (HBSC) study, an international repeated cross-sectional study. We used three proxy indicators of SES: an objective measure and two subjective measures (adolescents' perceptions of their own and their family's economic situation). The mental health indicator was psychosomatic symptoms. For each SES indicator, we analyzed the mental health trend using two standards of dividing SES subgroups (absolute vs. relative standard) and mental health (mean vs. top 90% cut-off score).

Results:

The long-term trend of adolescent mental health varied by the SES indicator used. The objective SES measure did not differentiate mental health across different SES groups and the subjective measure of adolescents' own economic situation did so in terms of the level but not the trend. The subjective measure of the family's economic situation revealed SES gaps in mental health in terms of both the level and the trend.

Conclusions:

Adolescents' perceptions of their family's economic situation has a greater discriminant value than the other SES measures to identify SES gaps in mental health in Sweden. Thus, the trend in adolescent mental health across different SES groups varies depending on how SES and mental health are operationalized. We call for efforts in other countries to report trends with varying measures of SES and mental health. This will help identify vulnerable groups in each country and facilitate well-informed international comparisons.

Key messages:

- This study shows that the long-term trend in adolescent mental health according to one's SES may meaningfully differ depending on how SES and mental health are operationalized.
- This study calls for future studies in other countries for a more precise identification of vulnerable groups and for a facilitation of well-informed international comparison.

Determination of mental status of the university students and related risk factors

Cansu Erden Cengiz

C Erden Cengiz[1], A Topuzoğlu[1]
[1]Public Health, Marmara University School of Medicine, Istanbul, Turkey
Contact: ccansuerden@gmail.com

University time is one of the most challenging periods of a person's life. It's also peak period of many mental illnesses. Mental disorders are the most important cause of disability in people aged 10-24 and contribute to 45% of the disease burden. The aim of this study is to determine the frequency of mental illness of university students in the research population and to assess the possible risk factors.

This study is a cross-sectional study. 345 students systematically selected by population weighting method were included in the study. Dependent variable of the study is depression, generalized anxiety, bipolar disorder and presence of psychotic symptoms. Mental disorders were evaluated using the CIDI and the DSM-5 Oriented Diagnostic Interview Form. 30.1% of the students had depression, 25.2% had generalized anxiety disorder, 9% had bipolar disorder and 2.9% had psychotic symptoms. The mean age of the participants is 20.4 ± 1.6. According to the binary logistic regression analysis, mother with mental problems, sexual abuse, person with special needs in family, pessimistic personality were found as risk factors for depression. Female gender, stay in a dormitory, poor economic condition of the family, mother with mental problems, alcohol/substance use of parent, pessimistic personality, lack of confidence were risk factors for generalized anxiety disorder. Alcohol use was risk factor for bipolar disorder. Poor academic achievement, having the family excluded by society were risk factors for psychotic symptoms. Average income level was a protective factor for bipolar disorder. Approximately one out of every 3 students use alcohol, and one out of every 20 students found to be at risk by using drugs.

The incidence of mental disorders in university students is high. Many factors play a role in the emergence of mental problems. Early recognition of mental disorders, effective control and intervention studies are highly valuable in universities.

Key messages:

- The social negative attitude developed against psychiatric diseases and patients has a direct effect on the prevention, early recognition and treatment of mental disorders.
- University students should be seen as a risky group for substance use, policies should be developed to prevent substance use at universities immediately.

Mental health problems and support needs of PhD students: bottle necks of the phD trajectory

Claudia Van Der Heijde

CM Van Der Heijde[1], L Douwes[1], P Vonk[1]
[1]Student Health Service, University of Amsterdam, Amsterdam, Netherlands
Contact: c.m.vanderheijde@uva.nl

Background:

A substantial part of PhD students is struggling with mental health problems. These complaints can lead to dropping out and societal costs. Various bottlenecks that students may face during the PhD process can undermine mental health. We aim to test what bottlenecks are predictive of mental health problems. Furthermore, we aim to address the responsibility of the University.

Methods:

In a cross-sectional survey design (N = 427), both mental health status, and possible bottlenecks of the PhD trajectory were studied amongst PhD students at the University of Amsterdam. Mean age was 29 years; 29% was male; 71% female. Participants were recruited through emails and newsletters (response rate 14%). Regression analysis' were performed with depression and anxiety as dependents (k6, ek10). We controlled for gender, age, international PhD student yes/no.

Results:

PhD students that score higher on anxiety, are more often international students (β=.09; p<.05), score significantly higher on negative work home interference (β=.46; p<.001), and on negative home work interference (β=.12; p<.01), score significantly lower on social support (β=.19; p<.001) and on self-efficacy (β=-.18; p<.001). [F(15, 413) = 20.00; p = .000]. PhD students that score higher on depression score significantly higher on negative work home interference (β=-.54; p<.001), and on negative home work interference (β=-.07; p<.05), score significantly lower on social support (β=-.23; p<.001) and on self-efficacy (β=.03; p<.001). [F(15, 416) = 41.68; p = .000].

Conclusions:

The bottlenecks that we found to be predictive of a worse mental health status can be addressed in the university context through providing information to PhD students, PhD supervisors and PhD student counselors. Extra attention needs to be paid to international PhD students. The University could offer interventions such as coaching, career guidance, relaxation training, time management, intervision, and sports to meet support needs.

Key messages:

- Work home interference, home work interference, social support and self-efficacy are important aspects of mental health in PhD students. Extra attention needs to be paid to international PhD students.
- The University has a responsibility and an interest regarding its PhD students' mental health and wellbeing: appropriate interventions can be deployed for the support needs of PhD students.

Healthcare use prior to suicide in the Stockholm County population 2011-2016

Jurgita Narusyte

J Narusyte[1,2], *K Kosidou*[1,2], *C Dalman*[1,2]
[1]Stockholm County Council, Stockholm, Sweden
[2]Karolinska Institutet, Stockholm, Sweden
Contact: jurgita.narusyte@ki.se

Background:

Suicide is a major public health problem. A detailed description of healthcare use prior to suicide can serve to improve prevention strategies. The aim of the study was to describe the patterns of primary, specialized outpatient, and inpatient healthcare use from two weeks and up to one year prior to suicide in Stockholm County.

Methods:

The study population included all 15 year or older suicide victims who died in Stockholm County 2011-2016 (n = 1950) identified through National Cause of Death Registry. Data on number of visits and contacts with healthcare among suicide victims were obtained from VAL healthcare use registry in Stockholm County. Healthcare use was depicted from one year to up to two weeks prior to suicide death.

Results:

Preliminary results showed that there were 65% and 57% of women and men, respectively, who had at least one contact with healthcare during the last two weeks before suicide death. Measured one year prior to suicide, there were 93% of women and 85% of men who had at least one contact with healthcare. Among those who had at least one contact with healthcare two weeks prior to suicide, there were 16% of women and 12% of men who were hospitalized, 55% of women and 47% of men who had a contact with specialized outpatient care, and 32% of women and 27% of men who had a contact with primary healthcare. The proportion of those who did not have any contact with healthcare during the six months prior to suicide decreased gradually with increasing age among men (23% at ages of 15-24 years old and 7% at ages of 65 and older). There were on average 7% of women in all age groups who did not have any contact with healthcare during the six months prior to suicide.

Conclusions:

The majority of the suicide victims had a contact with healthcare during the last year prior to suicide death. The findings suggest that suicide prevention efforts may target improved tools for clinically-based risk assessment.

Key messages:

- The majority of the suicide victims had at least one contact with healthcare during the last year prior to suicide death.
- Those who did not have any contact with healthcare during six months prior to suicide were more likely to be young men.

Childhood adversities and related mental health among children in socialization centers

Aurelija Peciukaityte

A Peciukaityte[1], *M Jakubauskiene*[1]
[1]Faculty of Medicine, Vilnius University, Vilnius, Lithuania
Contact: aurelija.peciukaityte@gmail.com

Background:

Life course paradigm provides a comprehensive overview of different determinants and mental health outcomes during the life course. Childhood adversities experienced in early adulthood are related to poor mental and physical health in the future. The aim of the study was to identify relations between experienced childhood adversities and mental health outcomes among children in socialization centers and regional high schools (HS) in Lithuania.

Methods:

A prevalence study was conducted in all 3 socialization centers (SC) in Lithuania (n = 35) and two regional high schools (n = 96) among 13-18 year old's. Anonymous individual interviews were conducted in 2018. Descriptive statistics using SPSS was applied for assessment of adverse life events, mental health risk factors and outcomes (%). Pearson chi square, Fisher test, Kruskal - Wallis H were applied for comparison and statistical significance ($p \leq 0{,}05$).

Results:

Prevalence of bullying among children in SC was 77.1% (47.9% among HS children), parental divorce - 60% (27% HS), parental criminal behavior - 40 % (2.1% HS), family violence - 48.6% (16.7% HS), physical abuse - 62.9% (9.4% HS), parental alcohol use - 40% (13.5% HS). 74.3% among children in SC experienced neglect, physical traumas (39.6% HS), prevalence of suicidal behavior was 25.7% and 6.25% accordingly. Criminal behavior, alcohol, substance abuse and smoking were much more prevalent among children in socialization centers than among high school children ($p < 0.01$).

Conclusions:

Children in socialization centers had higher exposure of childhood adversities and poorer mental health outcomes. High prevalence of adversities was related to poor parenting skills as well as toxic family and social environment.

Key messages:

- Childhood adversities experienced in early adulthood are related to poor mental and physical health as well as deprivation of social performance in later life.
- Childhood adversities are more prevalent among children in socialization centres than in regional high schools.

Benefits of non-drug interventions for people with suicidal crises in unipolar depression

Elke Berger

E Berger[1], *S Fuchs*[1], *N Baier*[1], *H Peters*[2], *R Busse*[1]
[1]Department of Health Care Management (MiG), Berlin University of Technology, Berlin, Germany
[2]Psychotherapeutic group practice Friedenau, Berlin, Germany
Contact: elke.berger@tu-berlin.de

Background:

Depression is one of the most common and serious diseases worldwide: According to WHO, more than 300 million people worldwide were affected by depression in 2015. In this group, the suicide rate is about 20 times higher than the population average. In Germany, around 10,000 people take their lives each year, many of them suffering from depression. The Institute for Quality and Efficiency in Health Care commissioned the Department of Health Care Management at the Berlin University of Technology to conduct a Health Technology Assessment on whether non-drug interventions influence coping with suicidal crises in unipolar depression.

Methods:

A systematic search of primary studies and systematic reviews (e.g., in MEDLINE, PSYCINFO) was performed to assess the benefit of ambulatory crisis intervention programmes or psychosocial interventions compared to another non-drug treatment, drug treatment, inpatient treatment or no treatment/waiting list in adult suicidal patients with unipolar depression regarding patient-relevant outcomes (e.g., suicide attempts, suicidal ideation, depression).

Results:

The search yielded a total of 4,159 hits. After two rounds of screening for relevance and removing duplicates, 4 studies remained for inclusion in the qualitative and quantitative analysis. The studies present RCTs assessing the effects of cognitive behavioural therapy (CBT) of the 2. and 3. wave - all short-term programmes focussing on suicidality. Results indicate a benefit of CBT compared to standard treatment, depending on the outcome, on the "wave" and on the time of follow up assessment.

Conclusions:

There is some evidence on benefits of CBT for adult patients with suicidal crises in unipolar depression. However, the quality of the included RCTs is weak and evidence on benefits of other non-drug interventions in outpatient care is missing. Further research is needed to identify effective interventions, especially for the vulnerable weeks immediately after suicide attempt.

Key messages:

- Short term cognitive behavioural therapy with suicidal prevention elements may influence coping with suicidal crises in unipolar depression positively.
- Further research is needed to identify effective interventions for the vulnerable weeks immediately after suicide attempt.

Mental wellbeing among the oldest old, living in nursing home or at home

Marian Ådnanes

M Ådnanes[1], L Melby[1], J Kaasbøll[1,2], J Kalseth[1]
[1]Department of Health Research, SINTEF, Trondheim, Norway
[2]Regional Centre for Child and Youth Mental Health, The Norwegian University of Science and Technology, NTNU, Trondheim, Norway
Contact: marian.adnanes@sintef.no

Background:

People 80 plus are the fastest growing age-group in Europe. While research is focusing on health deficiencies and losses and need for medical care and follow up, life conditions and mental health of older people are fields with insufficient knowledge. The promotion, maintenance, and improvement of well-being in this group is a great public health concern. This study aimed to explore differences in perspectives of what contributes to mental wellbeing (MWB) within three groups of persons 80 plus: 1) living at home, 2) living at home and attending day center some weekdays, 3) living in nursing home.

Methods:

A qualitative approach was followed, with six focus groups - two in each of the three categories. 35 persons were recruited from senior community centers, adult day care centers, and nursing homes. Data was assessed using qualitative content analysis.

Results:

The preliminary results from our study show significant variations between the three groups of participants in their perspectives on what contributes to MWB for them. In group 1 and partly group 2, engagement in fruitful or inspiring activities and insightful experiences with friends strongly associated with MWB. While the relevance of these factors also was mentioned by participants in group 3, they at the same time pointed at the limitations of living in a nursing home. Staying healthy and maintaining independence positively contributed to MWB in all three groups, however highly relatively, based on the person's actual health situation. Having close relationships with family and friends were considered important in all three groups.

Conclusions:

Perspectives on what contributes to MWB among persons 80 plus varies a lot as they control for what is possible based on own health and functionality, but also on what is accessible depending on institutional limitations. While such conditions are partly accepted, there is a potential for better MWB, simply based on more and/or better initiatives.

Key messages:

- Perspectives on what contributes to mental wellbeing among the oldest old varies a lot based on health and functionality, and on what is possible and accessible within institutions for elderly.
- There is a potential for better mental wellbeing based on more and/or better initiatives.

Use of antidepressant medication in Côte d'Ivoire (2017-2018)

Jerome Kouame

J Kouame[1,2], SS Oga[1], K Koffi[1], R Attia-Konan[1,2], ML Tiade[1], YP Yapi[3], L Kouadio[1]
[1]School of Pharmacy, University Felix Houphouet Boigny, Abidjan, Cote d'Ivoire
[2]Centre for Population and Health Systems Research, National Institute for Public Health, Abidjan, Cote d'Ivoire
[3]Methods and development department, Mutual Insurance Company for Civil Servants and Agents of the State of Côte d'Ivoire, Abidjan, Cote d'Ivoire
Contact: jerome.kouamejj@gmail.com

Background:

Like industrialized countries, people in developing world are increasingly exposed to mental disorders. Antidepressant drugs play a major role in the treatment of these disorders. The objective of this study was to describe the use of these drugs in Côte d'Ivoire based on data from a mutual health insurance company.

Methods:

This is a retrospective analysis of the health care consumption data from the mutual insurance company for civil servants and agents of the State of Côte d'Ivoire (MUGEFCI). The sample consisted of members and beneficiaries aged twenty (20) years and over who had taken at least one antidepressant drug reimbursed by the mutual insurance company between January 1, 2017 and December 31, 2018. Consumption was described for each drug and expressed in defined daily doses (DDD)/1000 inhabitants/day.

Results:

The sample consisted of 5712 people aged 20 to 88 years with an average age of 50.61±12.02 years. There was a male predominance with a sex ratio of 1.10. The number of prevalent users was 3135 in 2017 and 2607 in 2018. The number of incident users in 2018 was 2013. 10871 'boxes' of antidepressant drugs were consumed during the study period (52.11% in 2017 and 47.89% in 2018). Amitriptyline (52.71 DDD/1000 inhabitants/day in 2017), fluoxetine (8.60 DDD/1000 inhabitants/day in 2017) and paroxetine (3.32 DDD/1000 inhabitants/day in 2017) were the most used drugs. Their consumption increased by 11.82%, 3.71% and 41.03% respectively in 2018. Venlafaxine (0.37 DDD/1000 inhabitants/day in 2017) was among the least used molecules. Its consumption fell by 52.53% in 2018.

Conclusions:

The overall trend was an increase in antidepressant use, with a significant proportion of new users.

Key messages:

- Depression is a public health problem that is still relevant in developing countries.
- Depression mainly affects young adults and can influence their productivity.

Sleep and Mental Health Among Older Adults in the Canadian Longitudinal Study on Aging

Saverio Stranges

R Rodrigues[1], K Nicholson[1], P Wilk[1,2,4], G Guaiana[1,3], S Stranges[1,5,6], KK Anderson[1,2,3]

[1]Department of Epidemiology and Biostatistics, Western University, London, Canada
[2]Lawson Health Research Institute, Western University, London, Canada
[3]Department of Psychiatry, Western University, London, Canada
[4]Department of Paediatrics, Western University, London, Canada
[5]Department of Family Medicine, Western University, London, Canada
[6]Department of Population Health, Luxembourg Institute of Health, Strassen, Luxembourg
Contact: saverio.stranges@uwo.ca

Background:

Global studies have demonstrated consistent associations between sleep problems and mental health and well-being in older adults, however Canadian data are lacking. We investigated associations between sleep quantity and quality with both mental illness symptoms and well-being among older adults in Canada.

Methods:

We used cross-sectional baseline data from the Canadian Longitudinal Study on Aging, a national survey of 30,097 community-dwelling adults aged 45 years and older. Self-reported sleep measures included average past-week sleep duration (short [<6h], normal [6-8h], long [>8h]), and sleep quality (satisfied or dissatisfied vs neutral). Mental illness outcomes included depressive symptoms and psychological distress. Mental well-being outcomes included self-rated mental health and satisfaction with life. We used modified Poisson regression models with adjustment for sociodemographic, behavioural, and clinical factors, and stratification by sex and age to explore effect modification.

Results:

In the unadjusted analysis, short and long sleep duration and sleep dissatisfaction were associated with higher mental illness symptoms and lower well-being across all outcomes. Sleep satisfaction was associated with a lower likelihood of mental illness symptoms and better well-being. Short sleep duration was associated with the largest effects on mental health outcomes. Self-rated mental health and depressive symptoms had the largest associations with sleep measures. Effects were larger in males and the 45 to 54 year age group.

Conclusions:

Preliminary evidence suggests sleep duration and quality are associated with symptoms of depression, psychological distress, and poor mental well-being among older adults. We are unable to determine whether sleep problems are a cause or consequence of poor mental health. Nonetheless, sleep may be an important target for public health initiatives to improve mental health and well-being among older adults.

Key messages:

- Our findings contribute further evidence that sleep difficulties are associated with adverse health outcomes including higher mental illness symptoms and lower well-being among older adults.
- Sleep disturbances are an unmet public health problem, and may be an important target for public health initiatives to improve mental health and well-being among older adults.

Suicide in Polish migrants to Scotland

Dermot Gorman

DR Gorman[1], P Mackie[2], M Czarnecka[3], R King[1], W Wojcik[4]

[1]Public Health, NHS Lothian, Edinburgh, UK
[2]Knowledge and Research Services, NHS Health Scotland, Edinburgh, UK
[3]Project Management, Feniks, Edinburgh, UK
[4]Liaison Psychiatry, Royal Infirmary Edinburgh, Edinburgh, UK
Contact: dermot.gorman@nhslothian.scot.nhs.uk

Background and Methods:

Suicide amongst the 91,000 Polish nationals living in Scotland has been identified as a concern by the Polish Consulate. The adult suicide rate in Poland is 20.8 / 100,000 EASR population (Eurostat Suicide and Undetermined combined 2012-15). This is significantly higher than the 2012-16 Scottish level of 14.1 / 100,000 National Records of Scotland (NRS).

We set out to establish the picture for Polish migrants in Scotland and for 2012-16:

1. ascertained the number of such deaths from National Records of Scotland (NRS) describing the epidemiological features; and
2. reviewed Crown Office files of each person - extracting key information from police and pathology reports.

Results There were 68 suicide deaths in the 60 months. We estimated the European age standardised suicide rate (EASR) for all Polish residents in Scotland as 21.6 / 100,000 (95% CI 13.4 - 31.4) a suicide rate consistent with Poland not Scotland. The male:female ratio of 5.8:1 also mirrors Poland (vs. Scotland's 3:1 ratio). Polish men have a significantly higher rate than Scottish men - 31.5 vs 19.4 / 100,000. The suicide rates of Polish and Scottish women are very similar (5.4 vs 7.3 / 100,000 respectively).

Crown Office Records

A key finding is how similar the circumstances surrounding suicide deaths in both Polish and Scottish people are. In particular unemployment /irregular work, shift and manual work, relationship problems and alcohol use are all common. For Polish people in Scotland the challenges and stresses of the 'migrant experience' are superimposed onto other life events. Difficulties working in an English-speaking environment (and being unable to discuss emotional health), not knowing about the NHS Scottish public services and the lack of family and community networks to offer social support are all common.

Conclusions:

Actions are at four levels:

- National- the suicide action plan
- Employers
- NHS - staff awareness and monitoring trends
- Polish community groups

Key messages:

- Polish migrants to Scotland have a much higher rate of suicide than Scottish people - consistent with that in Poland.
- Addressing suicide requires examining factors in migrant and ethnic minority groups.

Gender differences in depression across Europe: a systematic review of cross-national studies

Daniel Hagen

D Hagen[1], E Goldmann[1]

[1]College of Global Public Health, New York University, New York City, USA
Contact: daniel.hagen@nyu.edu

Background:

Across countries and cultures, depressive disorders are more common among females than among males; however, the magnitude of gender differences varies between populations and may be a result of different country-specific social policies and cultural factors. This systematic review seeks to synthesise evidence from nationally representative, cross-national studies across Europe (EU-28 plus Switzerland and Norway) and to describe the impact of country-specific factors on gender differences in depression.

Methods:

PubMed, Web of Science, PsycInfo, and Embase were searched through March 2019 for peer-reviewed, nationally representative studies that included at least two European countries, used structured assessment for depressive disorders or symptoms, and reported or allowed for the calculation of gender ratios or differences. No restrictions on language or publication date were applied. Risk of bias was assessed using a tool specifically designed for population-based prevalence studies.

Results:

Twenty-one studies were included in this review, ten of which were based on surveys limited to older populations. Despite the use of different analytical approaches, metrics, scales, and cut-off points, depressive disorders were more common among females than among males in all but a few instances, with substantial variation in the magnitude of gender differences between countries and across studies. There is evidence of smaller gender differences in Northern Europe and greater gender gaps in Southern and Eastern Europe, as well as among older populations.

Conclusions:

Despite methodological heterogeneity between studies, there is evidence that gender differences in depression vary substantially across Europe. These differences may be associated with welfare state regimes and appear to be less pronounced in younger cohorts. Further cross-national research on gender disparities in depression between age groups, birth cohorts, and ethnic subpopulations is warranted.

Key messages:

- While depressive disorders are more prevalent among females than among males in virtually all of Europe, the magnitude of gender differences varies substantially between countries.
- There is some evidence that gender differences in depressive disorders are greater in countries with weaker welfare states and lower macro-level gender equality, as well as among older populations.

Farmers' health and wellbeing in the context of changing farming practice: a qualitative study

Madeleine Bondy

M Bondy[1,2], *D Cole*[1]
[1]Dalla Lana School of Public Health, University of Toronto, Toronto, Canada
[2]Faculty of Medicine, University of Ottawa, Ottawa, Canada
Contact: maddybondy@gmail.com

Background:

Farming continues to change globally, with steady industrialization, globalization and climate change and disproportionately high reports of stress and suicide. Little research has been done to understand how changes to farming impact mental health. We aimed to understand how Canadian farmers understand their stressors and experience their health.

Methods:

We recruited 16 small-medium scale, diversified farmers through farm organizations in Grey-Bruce counties in Canada. We interviewed them about their perception of changes in farming, associated stressors, mental health and well-being, and community supports. Using a constructivist paradigm, we coded each interview, discussed results, and formulated emergent themes using thematic analysis.

Results:

Farmers' relationship to change was complex with both benefits and challenges of changing farm practices, technology and weather for health - a ''double-edged sword''. Farmers described the resilience associated with farming which connects them to the land ''essentially being at one with place.'' Farmers' work required them to be active, an asset for keeping them healthy, but also a challenge if mobility became restricted. Farmers' noted overwhelming stress but stated ''...the last thing most farmers want to do is admit that they are stressed or have a mental health issue.'' Yet ''...if you don't have strong mental health then you can't really be resilient and cope with the stresses of climate change and all the things that will happen on a farm.'' They voiced a perceived lack of support from governments - dealing with bureaucracy, community - experience of isolation or stigma, and health services - an over-stretched, often distant system.

Conclusions:

Farmers' understandings from Canada will be compared to literature from Europe to demonstrate relevance inform public health programs promoting mental health in rural communities, advocacy for government supports to diversified farmers and evaluation of intervention programs.

Key messages:

- Farmers experience change as a double edged sword with benefits and challenges for health and mental health.
- Public health needs to intervene to meet farmers where they are and to advocate with farmers for further support.

Abortion and psychological distress in Icelandic women

Runar Vilhjalmsson

R Vilhjalmsson[1]
[1]School of Health Sciences, University of Iceland, Reykjavik, Iceland
Contact: runarv@hi.is

Background:

Previous research into the psychological consequences of abortion has presented misleading results, as some studies suggest negative consequences and others do not.

The current study focuses on the relationship between having or not having an abortion and psychological distress in the form of depression, anxiety and anger.

Methods:

The study uses data from 792 female participants in a random national health survey of Icelandic adults, age 18-75. The survey was conducted in the Spring of 2015. Respondents were given the option of answering an anomymous study questionnaire via mail or online (response rate 58%). The questionnaire asked respondents about psychiatric and physical conditions requiring medical attention in the past 12 months, stressful life-events in the past 12 months, and ongoing life-strains. Female respondents were asked whether or not they had had an induced abortion in the past 12 months. Psychological distress during the past week was assessed with the depression, anxiety, and anger subscales of the SCL-90 checklist.

Results:

Women who had had an abortion (2% of female respondents) reported higher levels of anxiety, depression, and anger than other women. The differences were statistically significant when controlling for age, education, family income, previous psychiatric and physical conditions, and previous stressful life-events and life-strains.

Conclusions:

The study indicates that women who have had an abortion are worse off psychologically than other women, and the difference is only partially accounted for by previous mental and physical health, or previous stressful circumstances. Health services for women considering abortion should be carefully considered, psychological distress assessed, and ways explored to ameliorate the distress they may experience following the abortion.

Key messages:

- Abortion is related to higher levels of anxiety, depression and anger in Icelandic women.
- Health services for women considering abortion should be carefully considered and psychological distress assessed.

Physical education, leisure time physical activity, and psychological distress in adolescence

Runar Vilhjalmsson

R Vilhjalmsson[1]
[1]School of Health Sciences, University of Iceland, Reykjavik, Iceland
Contact: runarv@hi.is

Background:

Participation in physical education classes can positively affect mental and physical well-being in children and adolescets. The current study focused on the relationship between participation in gym and swimming classes and psychological distress symptoms in Icelandic adolescents.

Methods:

The analysis is based on a national school-based study, conducted in Iceland every fourth year, as part of the WHO collaborative cross-national survey titled Health Behavior in School-Aged Children (HBSC). Data collection took place between November 2013 and February 2014. Students filled out an anonymous study questionnaire in the classroom. The data is based on responses from 15 year old (10. grade) students attending the final year of compulsory school (N = 3618; response rate 81%).

Results:

Positive associations were observed between participation in curriculum-based gym and swimming classes and lower psychological distress symptoms. A closer multivariate path analysis suggested that beneficial effects of PE classes were direct, and also indirect because participation in such classes were positively related to leisure time physical activity.

Conclusions:

The study suggests that school-based physical activity enhances psychological well-being in adolescence. The benefits may be both direct and indirect through increased leisure time physical activity.

Key messages:

- School-based physical activity enhances psychological well-being in adolescence.
- The benefits may be both direct and indirect through increased leisure time physical activity.

Elderly drivers with dementia – how do experts and relatives assess their safety risk?

Birgit Reime

B Reime[1], *N Pilgram*[1], *T Bertsche*[1]
[1]Department of Applied Health Promotion, HS Furtwangen, Furtwangen, Germany
Contact: Birgit.Reime@hs-furtwangen.de

Background:

Demographic change increases the proportion of car drivers over the age of 70. With increasing age, the likelihood of developing a form of dementia increases. In Germany, about 1.6 million people suffer from dementia. Surveys among dementia patients showed that about two-thirds said they held a valid driving licence and just under half reported still actively driving. We explored whether and to what extent motorists with dementia are putting road safety at risk and how relatives deal with the driving behaviour of their elders.

Methods:

Semi-structured qualitative interviews were conducted with seven experts from the fields of police, gerontology and geriatrics as well as with 16 relatives of patients with different stages of dementia. All interviews were then transcribed. The analyses based on the qualitative content analysis (Mayring 2015) with MAXQDA.

Results:

The experts regarded elderly drivers with dementia as a public health relevant safety risk. Among those elders who are affected by dementia the awareness of the problem often is limited and not rarely they are characterized by an unsafe driving style. Experts from Austria and Switzerland supported the concept of a mandatory dementia assessment for elderly drivers while experts from Germany did not. Relatives reported very similar descriptions of their elderly's driving characteristics. Furthermore, the cognitive and motor limitations associated with dementia often are not noticed by both patients themselves and their relatives.

Conclusions:

Representative studies are needed to test which measures, such as a mandatory dementia check from retirement age, are likely to improve the safety of older drivers with dementia. Family doctors and GPs should address and educate dementia patients in relation to their risk of accidents. Relatives should receive information material on how to communicate with their elderlys on this topic to maximize safety while avoiding conflict.

Key messages:

- The prevalence of elderly drivers with dementia is unknown.
- Representative studies are needed to test best practice appoaches for harm reduction in drivers with dementia.

DS Epidemiology, public health monitoring and reporting

Large sociodemographic differences in response rates and methods in a population survey in Sweden

Anu Molarius

A Molarius[1,2], *C Persson*[3], *J Lindström*[3], *M Lindén-Boström*[3]
[1]Centre for Clinical Research, Region Värmland, Karlstad, Sweden
[2]Department of Public Health Sciences, Karlstad University, Karlstad, Sweden
[3]Department for Sustainable Development, Region Örebro County, Örebro, Sweden
Contact: anu.molarius@regionvarmland.se

Background:

Declining response rates in population surveys may decrease the representativeness and introduce bias in survey results. This study investigated sociodemographic differences in response rates and methods in a population survey in Sweden.

Methods:

The study is based on a large population survey conducted in five counties in Mid-Sweden in 2017. Three age-specific questionnaires for persons 18-29, 30-69 and 70 years or older were designed to study living conditions, life style factors and health. The sample was random and stratified by gender, age group and municipality, and comprised 78 000 persons 18 years or older. Up to two reminders were sent, the last reminder consisted of a short version of the questionnaire. The survey could be answered using a written questionnaire or on-line. The web-questionnaire was available in Swedish and English.

Results:

The overall response rate was 44% with the lowest participation rate in ages 18-29 years (26%) and highest in ages 70-84 years (70%). Women, persons with high educational level, and persons born in Sweden were more prone to respond than others. Those aged 18-29 years were overrepresented in the sample and the participation rate would have been 46% if the sample had been unstratified by age. The majority of the respondents answered the written questionnaire, even though it was more common that younger people responded via the web compared to older people. In total, 8% of the respondents replied to the short form and this was most common (17%) among those born outside the Nordic countries.

Conclusions:

In line with previous research, the results indicate large sociodemographic differences in response rates. The response methods also vary between sociodemographic groups, and knowledge about these differences may be helpful when designing future population surveys.

Key messages:

- The response rate was higher among older people, women, persons with high educational level, and persons born in Sweden than among other groups.
- Persons born outside the Nordic countries were most prone to respond to the short form and younger people replied more often to the web-questionnaire than older people.

Added value of combining health examination surveys and human biomonitoring studies

Hanna Tolonen

H Tolonen[1], AM Andersson[2], S Agergaard Holmboe[2], S Namorado[3], L Rambaud[4], M Kolossa-Gehring[5]
[1]Department of Public Health Solutions, The National Institute for Health and Welfare, Helsinki, Finland
[2]Department of Growth and Reproduction, Rigshospitalet, The Capital Region of Copenhagen, Copenhagen, Denmark
[3]Department of Epidemiology, National Institute of Health Doutor Ricardo Jorge (INSA), Lisbon, Portugal
[4]Environmental Health Division, Santé Publique France, Paris, France
[5]German Environmental Agency (UBA), Berlin, Germany
Contact: hanna.tolonen@thl.fi

Background:

In many European countries, parallel to health examination surveys (HES), human biomonitoring (HBM) studies are conducted to monitor chemical exposures of the population. HES and HBM studies use survey based data collection with similarities in sample selection and recruitment, ethics and data protection, collection of data by questionnaire and through biological samples.

Methods:

In the framework of European Human Biomonitoring Initiative (HBM4EU), evaluation of opportunities and potential obstacles related to combining HES and HBM surveys has been conducted. Experiences and expectations of principal investigators (PI) of studies from 19 European countries have been evaluated.

Results:

The most common reasons for omitting an HBM module from a HES were lack of knowledge related to chemical measurements, lack of funding and capacities for chemical analysis. Many PIs feared that adding an HBM module to their survey would increase the participant burden and decrease participation rate. In surveys where these two different modules were already combined, the biggest benefits were seen on use of same infrastructure for recruitment of survey invitees, collection of questionnaire information and biological samples, and additional information on health, resulting more cost-effective data collection with more information on each participant. Combining these two modules had challenges on fitting together needs from the two study objectives. While survey content broadens, balancing participant burden and research interest of both HES and an HBM module is challenging. The amount of collected biological samples such as blood samples is limited. Coordination of the activities between several research groups can be challenging and time consuming.

Conclusions:

Several examples have shown that combining HBM and health surveys is possible and provide several benefits. However, it requires a good preparation and planning and sufficient coordination capacity to be successful.

Key messages:

- Combining HES and HBM is possible but requires detailed planning and good collaboration between research groups.
- Combined HES and HBM studies provide a wide range of information about population health status and its determinants as well as chemicals levels of exposure.

Comparison of the difference between income quintiles with the slope index of inequality

Young-Ho Khang

YH Khang[1,2], D Lim[2], J Bahk[3], I Kim[1], HY Kang[1], Y Chang[1], K Jung-Choi[4]
[1]Department of Health Policy and Management, Seoul National University College of Medicine, Seoul, South Korea
[2]Institute of Health Policy and Management, Seoul National University Medical Research Center, Seoul, South Korea
[3]Department of Public Health, Keimyung University, Daegu, South Korea
[4]Department of Occupational and Environmental Medicine, Ewha Womans University School of Medicine, Seoul, South Korea
Contact: yhkhang@snu.ac.kr

Background:

The difference between income quintiles in health is relatively well accepted by the general public as a measure of health inequality. However, the slope index of inequality (SII) in health reflects the patterns of all social groups, including the middle 60%, and it could therefore be considered more academically desirable. If these two measures are closely correlated, the widespread use of the difference between income quintiles in health would be better supported. This study was conducted to compare differences between income quintiles in life expectancy (LE) and healthy life expectancy (HLE) with the SII.

Methods:

Data on LE and HLE by income quintile from all 252 subnational districts of Korea were obtained using the National Health Information Database of the National Health Insurance Service and the Korea Community Health Survey. The SII was estimated with linear regression analysis, and Pearson correlation coefficients between differences between income quintiles and the SII were computed.

Results:

The correlation coefficients between differences between income quintiles and the SII were generally high: 0.97 (95% CI: 0.96-0.98) for LE in men and women combined and 0.96 (95% CI: 0.94-0.97) for HLE in men and women combined. In most districts, the SII was greater than the difference between income quintiles.

Conclusions:

Differences between income quintiles were closely correlated with the SII. The widespread use of differences between income quintiles in health as a measure of health inequality may be preferable for communicating results of health inequality measurements to the public.

Key messages:

- Differences in life expectancy and health life expectancy between income quintiles were closely correlated with the slope index of inequality in life expectancy and healthy life expectancy.
- The widespread use of differences between income quintiles in health as a measure of health inequality may be preferable for communicating results of health inequality measurements to the public.

Does diet quality mediate socioeconomic differences in metabolic syndrome in the French West Indies?

Zoé Colombet

Z Colombet[1], M Perignon[1], B Salanave[2], E Landais[3], Y Martin-Prével[3], B Allès[4], S Drogue[1], M-J Amiot-Carlin[1], C Méjean[1]
[1]MOISA, INRA, Montpellier, France
[2]ESEN, French Public Health Agency, Bobigny, France
[3]UMR204-Nutripass, IRD, Montpellier, France
[4]EREN, INRA, Bobigny, France
Contact: zoe.colombet@inra.fr

Background:

Obesity and metabolic diseases represent a major health burden in the Caribbean, particularly since a large part of the population is disadvantaged. However, socioeconomic inequalities in chronic diseases are poorly explored in this region, and the contribution of diet to explain these inequalities has not yet been studied. We investigated the association between socioeconomic position and the prevalence of metabolic syndrome (MetS), and explored whether this association was mediated by diet quality in the French West Indies.

Methods:

This cross-sectional analysis included 1,144 adults ($\geq$16 y) from a multistage sampling survey, representative of the

Guadeloupean and Martinican population. The prevalence of MetS was assessed using the Joint Interim Statement. Dietary intakes were estimated using 24hours dietary recalls, and diet quality was assessed through the Diet Quality Index-International (DQI-I). Associations between socioeconomic indicators (education, employment, social assistance benefits) and prevalence of MetS, and the potential mediating effect of diet quality in this association were assessed using multivariable logistic regression models adjusted for sociodemographic factors.

Results:

MetS prevalence adjusted for age and sex was 21% and 30% among Guadeloupean and Martinican, respectively. Compared to those with a high education level, low- and middle-educated subjects were more likely to be at risk of MetS (OR = 1.9; 95%CI = [1.0-3.6] and OR = 2.7; 95%CI = [1.4-5.1], respectively), as were recipients of social assistance benefits compared to non-recipients (OR = 2.2; 95%CI = [1.1-4.2]). The DQI-I explained 11% of the overall variation in MetS due to education.

Conclusions:

Socioeconomic inequalities in MetS prevalence were found in a Caribbean population but diet quality contributed only to socioeconomic inequalities due to education. Future public health measures need to target specifically populations with limited financial resources and low education.

Key messages:

- Our work identified subgroups with higher risk of MetS, which is needed when implementing public health measures, particularly in this Caribbean population with of high poverty rates.
- Diet quality contributed only to socioeconomic inequalities due to education underlining that education may impact health through the ability to generate overall dietary behavior, long-term beneficial.

What can dietary patterns tell us about the Caribbean nutrition transition?

Zoé Colombet

Z Colombet[1], B Allès[2], M Perignon[1], E Landais[3], Y Martin-Prével[3], M-J Amiot-Carlin[1], N Darmon[1], C Méjean[1]
[1]MOISA, INRA, Montpellier, France
[2]EREN, INRA, Bobigny, France
[3]UMR204-Nutripass, IRD, Montpellier, France
Contact: zoe.colombet@inra.fr

Background:

Given the public health urgency facing the increasing rates of obesity and chronic diseases in the Caribbean, characterization of the nutrition transition and population groups at higher nutritional risk is needed. We identified dietary patterns in the French West Indies (FWI) and their association with individual characteristics.

Methods:

This cross-sectional analysis included 1,144 Guadeloupeans and Martinicans from a representative survey. To identify dietary patterns, principal component analysis was performed using 25 food groups, followed by a clustering procedure classifying subjects in independent clusters. Their associations with health status, Diet Quality Index-International (DQI-I), food supply behaviors, sociodemographic and economic characteristics were studied using multivariable models.

Results:

Four dietary patterns were identified, representing 25%, 24%, 31% and 20% of the sample: (1) a ''healthy'' cluster characterised by a high DQI-I, composed of high educated individuals; (2) a ''traditional'' cluster with a high DQI-I and high intakes of traditional dishes, formed mostly by women and older persons, with a high obesity prevalence (26%); (3) a ''western'' cluster with a low DQI-I, high intakes of sweetened beverages, snacks and fast foods, composed mainly of young subjects, buying their fruits, vegetables and tubers only or mainly in supermarkets; and (4) a ''transitional'' cluster with high intakes of bread, processed meat, sauces, alcoholic and sweetened beverages but conversely high intakes of tubers, legumes, fish and low intakes of biscuits and cakes, formed mainly by middle age men, self-employed or manual workers, and 35% had metabolic syndrome.

Conclusions:

The dietary patterns identified reflect different steps of dietary change as described by Popkin, suggesting an ongoing nutrition transition in the FWI. This characterization provides useful information for public health actions regarding population groups at higher nutritional risk.

Key messages:

- Four diversified dietary patterns were identified suggesting an ongoing nutrition transition in the French West Indies.
- Demographic and socioeconomic characteristics associated with dietary patterns, especially age, reflecting a generational contrast, provided needed information to guide future public health measures.

Factors associated with mechanical and systemic adverse events after colonoscopy (France, 2010-2015)

Moussa Laanani

M Laanani[1,2], A Weill[1,2], PO Blotière[2], J Pouchot[3], F Carbonnel[4], J Coste[2,5]
[1]EPI-PHARE, Saint-Denis, France
[2]Department of Public Health Studies, French National Health Insurance, Paris, France
[3]Internal Medicine unit, Georges Pompidou European Hospital APHP, University Paris Descartes, Paris, France
[4]Gastroenterology Unit, Paris Sud University Hospitals, APHP, Le Kremlin-Bicêtre, France
[5]Biostatistics and Epidemiology Unit, Cochin Hospital APHP, University Paris Descartes, Paris, France
Contact: moussa.laanani@assurance-maladie.fr

Background:

More than one million colonoscopies are performed every year in France. They are associated with risks of mechanical and systemic serious adverse events (SAEs) which can be associated with patient, procedure, endoscopist, and facility characteristics. We tried to identify the factors associated with colonic perforation, gastrointestinal bleeding, splenic injury, shock, myocardial infarction, stroke, pulmonary embolism, acute renal failure, and urolithiasis after colonoscopy.

Methods:

We analysed data from the French national claims databases (SNDS). A total of 4,088,799 patients, 30 years or older, undergoing a first screening or diagnostic colonoscopy between 2010 and 2015 were identified. SAE rates were estimated, and risk factors associated with SAEs were identified using multilevel logistic regression models, adjusted for patient, colonoscopy, endoscopist, and facility characteristics.

Results:

Increasing age was associated with an increasing incidence of mechanical and systemic SAEs. Cancer and cardiovascular comorbidities were associated with mechanical SAEs, and a higher number of pre-existing conditions was associated with shock and acute renal failure. Polypectomy, especially of polyps larger than 1 cm, was associated with an increased risk of perforation (OR = 4.1; 95% CI, 3.4-5.0) and bleeding (OR = 13.3; 95% CI, 11.7-15.1). Mechanical SAEs were associated with the endoscopist's experience, while systemic SAEs were more frequent in public hospitals than in private clinics.

Conclusions:

SAEs related to colonoscopy were more frequent in older patients and in those with comorbidities. Mechanical SAEs were more frequent when colonoscopy was performed by less experienced endoscopists. Systemic SAEs were more frequent in public hospitals, reflecting patient selection processes. The risk of both mechanical and systemic SAEs should be taken into account when deciding to perform colonoscopy, particularly in older patients with multiple pre-existing conditions.

Key messages:

- Systemic SAEs are not uncommon after colonoscopy and, together with intestinal SAEs, should be considered when considering the need for colonoscopy.
- Patients at risk of SAEs should be identified and colonoscopy should be performed by experienced endoscopists in these patients. Less invasive alternatives should also be considered in these patients.

Determinants of self-rated general health among men and women 70 years or older in Sweden 2017

Carina Persson

C Persson[1], *A Molarius*[2,3], *J Lindström*[1]
[1]Department for Sustainable Development, Region Örebro County, Örebro, Sweden
[2]Centre for Clinical Research, Region Värmland, Karlstad, Sweden
[3]Department of Public Health Science, Karlstad University, Karlstad, Sweden
Contact: carina.persson@regionorebrolan.se

Background:

Goal 3 of the 2030 Agenda for Sustainable Development states that ensuring healthy lives and promoting the well-being at all ages is essential. But health and well-being still vary between different groups. The aim of this study was to find factors associated with self-rated health that can explain the differences among people 70 years or older in Sweden.

Methods:

The study is based on a cross-sectional population survey conducted in five counties in Mid-Sweden in 2017. An age-specific questionnaire for persons 70 years or older was used. The response rate was 65% and the study population included 9 482 persons who answered all questions used in the study. Multivariate binomial logistic regression with outcome good or very good self-rated general health was used for the analysis.

Results:

The overall prevalence of good or very good self-rated health was 54%. The factors with the strongest positive associations with good/very good self-rated health were: good appetite (OR: 4.48; 95% CI: 3.41-5.88) and physical activity (2.07; 1.87-2.29). The strongest negative associations were found for: need for help in everyday life (0.37; 0.24-0.57), troubled by loneliness once a week or more often (0.40; 0.34-0.47), obesity (0.55; 0.48-0.63), troubled by loneliness some times a month (0.59; 0.50-0.71), sedentary 10 hours/day or more (0.61; 0.52-0.72), and being patronized (0.65; 0.55-0.76). Other statistically significant positive factors were e.g. to have someone to confide in, participation in activities with others, trust in people in general, feeling safe in residential neighbourhood and access to personal support. Included in the analysis, but not statistically significant, were sex, country of birth and care of relatives.

Conclusions:

Good self-rated health is more common among persons 70 years or older who have good appetite, are physically active and have good social relations.

Key messages:

- To promote good self-rated health in persons 70 years or older it is essential to enhance possibilities for social interaction and social support.
- Also promoting healthy lifestyle in form of physical activity and healthy eating habits is important.

An online health status report to support public health in Belgium

Aline Scohy

A Scohy[1], *B Devleesschauwer*[1,2], *F Renard*[1]
[1]Department of Epidemiology and Public Health, Sciensano, Brussels, Belgium
[2]Department of Veterinary Public Health and Food Safety, Ghent University, Merelbeke, Belgium
Contact: aline.scohy@sciensano.be

Issue:

Monitoring population health is crucial for policymakers. In Belgium, health monitoring only existed at regional level, with no integrated view at country level.

Policy/tool:

The Health Status Report (HSR) project developed a tool for centralizing key health indicators. The HSR aims to support policymakers in multiple ways: as a 'warning signal', by contributing to the planning of health policies, and as an assessment tool for those policies. Rather than being exhaustive, the HSR selects key indicators to highlight important needs. These indicators have been identified through literature and consultations with experts and stakeholders. Topics include life and health expectancies, mortality, morbidity, and lifestyles, with an important focus on socio-economic inequalities. Good results and health gaps are underlined with international comparisons, trend analyses, and comparisons with reference values. By disaggregating the data by sex, age, geographic level or socio-economic level, specific health needs are identified.

Results:

The main outcome of the project is a continuously updated website: www.healthybelgium.be. The report highlighted that, although the Belgian health status is rather good, there is room for improvement: for some indicators Belgium lags behind other European countries; regional disparities remain important, with most indicators revealing a better health status in Flanders than in Brussels and Wallonia. Socioeconomic disparities also remain very important, and for some indicators even tend to worsen. Comparing the Belgian health status to that of the EU-15 results in more severe conclusions than in international reports.

Conclusions:

We developed a new tool to support public health policy in Belgium through benchmarking and trend and disparity analyses of several health indicators. The tool will be expanded in the next years, integrating for instance the results of the Belgian national burden of disease study.

Key messages:

- We developed an online health status monitoring tool to inform policymakers.
- The rather good health status hides important regional and socioeconomic disparities in Belgium.

Contamination of Poultry Meat with Salmonella infantis should be considered a Risk for Food Safety?

Guido Finazzi

G Finazzi[1], *B Bertasi*[1], *E Pavoni*[1], *V Filipello*[1], *M D'Incau*[2], *MN Losio*[1]
[1]Food Control, Istituto Zooprofilattico Sperimentale della Lombardia e dell'Emilia Romagna, Brescia, Italy
[2]Applied Biological Technologies, Istituto Zooprofilattico Sperimentale della Lombardie e dell'Emilia Romagna, Brescia, Italy
Contact: guido.finazzi@izsler.it

Issue/problem:

EU Regulation regarding fresh poultry meat considers only S. enteritidis or S. typhimurium as Food Safety Criteria. On the contrary, the isolation of other Salmonella spp. in this food matrices is considered compliant. Several bibliographical sources indicate an increase in the isolation trend of S. infantis in the poultry industry and in derived products.

Description of the problem:

Episodes of food poisoning caused by fresh chicken meat contaminated with S. infantis have been recently reported. According to CDC, last year in USA, an outbreak caused by a S. infantis strain, resistant to multiple antibiotics, ended with 129 sick people, 25 hospitalizations and a death. National Salmonellosis Control Plan for Poultry 2019-21 establishes in Italy the abatement conditions for poultry farms in case of positive isolation of S. enteritidis, S. typhimurium and S. infantis.

Results:

In 2018, the National Health System disposed the analysis of batches of fresh chicken meat from Poland, sampled in a cold storage facility in Northern Italy. Food Control Dept. of IZSLER analysed 156 samples for a total of 780 sampling units (s.u.), for Salmonella spp.: 72 samples were positive (46,15%;corresponding to 222 s.u. - 28,46%). 42 strains were serotyped as S. enteritidis, 149 as S. infantis, 26 as S. newport, 4 as S. kentucky and 1 as S. mbandaka. According to EU Regulation, batches positive for S. enteritidis were indicated as not compliant, but batches positive to other Salmonella were considered regular.

Lessons:

EU legislation allows the circulation of chicken meat contaminated with S. infantis. Chicken meat should be consumed after appropriate well cooking eliminating this hazard, but it does not protect the consumer from the risk of cross-contamination of tools and surfaces at the household level. It's therefore fundamental the application of correct processing practices in order to prevent the spreading of Salmonella in home kitchens and limit dangerous episodes of infection.

Key messages:

- S. infantis trend of isolation in the poultry industry is increasing.
- application of GMPs in home cooking is fundamental to limit food outbreaks of infection.

Illicit drug use among Croatian university students

Ivan Miskulin

I Miskulin[1], *I Vcev*[2], *I Gaspar*[1], *A Juric*[1], *A Barac*[1], *V Banovic*[1], *M Lovric*[1], *A Vcev*[1,3], *M Miskulin*[1]
[1]Faculty of Medicine Osijek, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia
[2]University of Zadar, Zadar, Croatia
[3]Faculty of Dental Medicine and Health Osijek, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia
Contact: ivan.miskulin@mefos.hr

Background:

Illicit drug (ID) use among university students has been recognized as a global public health issue in recent years. It has been emphasized that during university years' opportunities to experiment with ID increases due to the fact that this is a period of life characterized by transition, intense academic pressures as well as independence and separation from parental supervision. The aim of this study was to identify prevalence and characteristics of ID use among Croatian university students.

Methods:

This was a multicentric, cross-sectional study that included five Croatian universities. A validated, anonymous online questionnaire containing questions regarding demographic and data regarding ID, alcohol and tobacco use was self-administered to cross-faculty representative student sample of University of Osijek, Zagreb, Rijeka, Split and Zadar during November 2018.

Results:

The study sample included 888 students, the average age being 21.9 years (range 18-34); 18.4% males and 81.6% females. The overall prevalence of ID use among Croatian university students was 29.8%. The ID use was more frequent among males ($p = 0.001$) and among students who repeated the study year ($p < 0.001$). The study further revealed that there were 48.4% students who tried any type of ID during life. The majority of students tried ID for the first time during high school period (34.1%), when socializing with friends in open spaces such as parks (20.6%) and main reason for usage was to have fun (40.5%). The study also showed that there were statistically significant Spearman rank correlations between ID and alcohol use ($p < 0.001$) as well as between ID and tobacco use ($p < 0.001$).

Conclusions:

The usage of ID is highly prevalent among Croatian university students in participating universities. Further studies are needed to identify and explain other possible risk factors for this phenomenon.

Key messages:

- Illicit drug use is an important but poorly investigated public health issue among Croatian university students.
- Better understanding of specific characteristic and possible risk factor for illicit drug use among university student population will ensure development of preventive programs.

Validating record-linkage based methodology for addressing health survey non-participation

Linsay Gray

MA McMinn[1], *P Martikainen*[2], *T Härkänen*[3], *H Tolonen*[3], *J Pitkänen*[2], *AH Leyland*[1], *L Gray*[1]
[1]MRC/CSO Social and Public Health Sciences Unit, University of Glasgow, Glasgow, UK
[2]Population Research Unit, Faculty of Social Sciences, University of Helsinki, Helsinki, Finland
[3]Public Health Solutions, National Institute for Health and Welfare, Helsinki, Finland
Contact: linsay.gray@glasgow.ac.uk

Background:

As a consequence of declining levels of participation in health surveys, the results purported to be population-representative may be biased. Traditional adjustments for non-participation, such as weighting, can fail to correct for such biases. We aim to validate our developed methodology, which simulates non-participants, and compare results from the inferred sample to the 'gold standard' sample of participants and true non-participants, and participants alone.

Methods:

Participants and non-participants of the Finnish Health 2000 survey, and a contemporaneous population sample are available, with alcohol-related hospitalisations and deaths ("harms", individually record-linked for all Health 2000 invitees). Synthetic observations on non-participants were simulated through comparison of participants and population sample. Alcohol consumption of true and inferred non-participants were multiply imputed based on harms and education as well as age and sex, assuming data are Missing At Random (MAR). Results are compared via the relative differences (RD) between the inferred sample and 1) gold standard sample, and 2) participants alone.

Results:

Average weekly estimates for men are 129g in the inferred sample, and 130g in the gold standard (RD -1.2%, 95%CI -2.0, -0.4%), and 35g for women in both samples (RD -0.8%; -1.9, 0.3%). Estimates for men with secondary levels of education had the greatest RD (-1.9%; -3.3, -0.5%). Comparisons between the participants and the inferred sample revealed few differences.

Conclusions:

All RD between the inferred and gold standard samples lie within our ±5% acceptability limits, in support of the use of our methodology for adjusting for non-participation in health surveys. However, under MAR, there are no significant differences between the results generated from the inferred sample and the participants alone. Further work exploring Missing Not At Random scenarios is required to ensure utility for reliable population health monitoring.

Key messages:

- Survey weights alone cannot adjust for non-representativeness, but we have shown that data linkage can be used to match the characteristics and outcomes of the selected sample.
- Non-participation in health surveys may be adjusted for using our methodology, with further exploration into alternative missing data scenarios required.

Risk factors of addictive behavior in adolescents in Tunisia

Hela Ghali

H Ghali[1], *A Ben Cheikh*[1], *S Khefacha Aissa*[1], *M Tourki Dhidah*[1], *S Bhiri*[1], *Y Kaabi*[1], *W Ben Othman*[1], *M Ben Rejeb*[1], *H Said Latiri*[1]
[1]Department of Prevention and Security of Care, Sahloul University Hospital, Faculty of Medecine of Sousse, University of Sousse, Sousse, Tunisia
Contact: yasminebenrejeb@hotmail.com

Background:

Adolescence is a period of physical, psychological and sociocultural transformation, but also of curiosity and experimentation. In Tunisia, the levels of use of some psychoactive substances, especially alcohol, tobacco and cannabis, remain high among adolescents, despite progress in regulatory efforts to limit access to these products by minors, and regular prevention campaigns. We aimed to determine the prevalence of addictive behavior among students in the region of Sousse and to specify the risk factors.

Materials/Methods:

We conducted a cross-sectional epidemiological study in two public schools in the governorate of Sousse during the 2017/2018 school year. All students in each class were included when they agreed to participate in the study. The data was collected by anonymous self-questionnaire, then processed and analyzed using the SPSS version 20 software.

Results:

In total, 294 students participated in this study with a mean age of 17.03 ± 1.51 years. A female predominance was noted (56.1%). The prevalence of addictive behavior was 52% (95% CI = [45.9% - 57.8%]). In univariate analysis, male gender, advanced age, and repeating the study year were significantly associated with addictive behavior (p = 0.014, p < 10-3, p = 0.004 respectively). However, multivariate analysis showed that the probability of addictive behavior decreased in students who read books frequently (OR = 0.6, 95% CI = [0.37 - 0.96], p = 0.03). The only independent risk factor associated with addictive behavior was age (OR = 1.34, 95% CI = [1.14 - 1.59], p < 10-3).

Conclusions:

The findings have implications for identifying protection factors and risk factors for addictive behaviors, and the development of primary prevention strategies derived from such factors.

Key messages:

- Our results highlight the need to better understand behaviors at risk in Tunisia and the perceptions of prevention policies among students.
- Knowledge of related factors is important for prevention program planning.

What do patients consulting in a free STI center know about HIV transmission and prevention?

Christelle Duteil

C Duteil[1], E de La Rochebrochard[3,4], P Piron[1,2], C Segouin[1,2], P Troude[1,3]

[1]Department of Public Health, University Hospital Saint-Louis-Lariboisière-Fernand-Widal (AP-HP), Paris, France

[2]CEGIDD, University Hospital Saint-Louis-Lariboisière-Fernand-Widal (AP-HP), Paris, France

[3]Institut National d'Etudes Démographiques (INED), Paris, France

[4]University Paris-Saclay, University Paris-Sud, UVSQ, CESP, INSERM, Villejuif, France

Contact: christelle.duteil@aphp.fr

Background:

Despite therapeutic progress, HIV remains a public health issue with about 6400 new HIV contaminations each year in France. HIV prevention relies on health education, early screening, treatment as prevention, post and pre-exposure prophylaxis. Patients' visits to free sexually transmitted infections (STIs) screening centers (CeGIDD) are opportunities to spread prevention messages. This study aimed to assess level of HIV knowledge in a Parisian CeGIDD to improve prevention messages.

Methods:

The study included patients older than 18 who came for STIs testing between August 2017 and August 2018 and who understand written French language. Data were collected by a self-administered electronic questionnaire filled in before medical consultation. It included sociodemographic data and knowledge regarding HIV transmission and prevention.

Results:

The study included 2002 patients. The median age was 27 years and 66% were men. More than 96% of patients know that HIV transmission is possible through unprotected sexual intercourse and through needle exchange. However, some misconceptions persist: 20% of patients believe that HIV transmission is possible from using public toilets and 22% by mosquito bite. Prevention measures perceived as "absolutely or rather efficient" by patients were: using condom (97%), requesting a screening test from his partners (91%), getting screening tests regularly (90%), choosing his partners correctly (62%), having sex with few different partners (50%). Half of patients heard of post-exposure prophylaxis (51%).

Conclusions:

Main modes of HIV transmission are well known (unprotected intercourse and needle exchange). However, false beliefs regarding prevention may lead to risk behavior (doing screening test regularly doesn't protect against HIV) and need to be explored. Moreover, assessment of variation in level of HIV knowledge according to patient's profile may help to target prevention message according to specific populations.

Key messages:

- Main modes of HIV transmission are well known.
- False beliefs regarding modes of prevention need to be explored to target HIV prevention messages.

Alcohol use among 15–16-year-old adolescents in Estonia, 2003–2015

Kersti Pärna

K Pärna[1], D Kudre[1], S Vorobjov[2]

[1]Institute of Family Medicine and Public Health, University of Tartu, Tartu, Estonia

[2]Department of Drug and Infectious Diseases, National Institute for Health Development, Tallinn, Estonia

Contact: kersti.parna@ut.ee

Background:

Alcohol is one of the most common psychoactive substances used by adolescents. The aim of the study was to describe the prevalence of alcohol use in 2003-2015 and to analyse association of alcohol use with family- and school-related factors, other risk behaviors, and perceived alcohol availability.

Methods:

This study was based on data of 15-16-year-old adolescents (n = 9559) from the cross-sectional studies of European School Survey Project on Alcohol and Other Drugs conducted in Estonia in 2003-2015. Prevalence of past 30-day alcohol use was calculated for each study year. Chi-square test for trend was used to assess statistically significant changes of alcohol use over the study period. Logistic regression analysis was used to analyse association between alcohol use and study year, family- and school-related factors, risk behaviors, and perceived alcohol availability. Fully adjusted odds ratios with 95% confidence intervals were calculated.

Results:

In 2003-2015, alcohol use decreased significantly among adolescents in Estonia ($p < 0.001$). In 2015, the prevalence of alcohol use was 36.1% (95% CI $33.4 - 38.8$) among boys and 39.1% (95% CI $36.3 - 41.8$) among girls. Fully adjusted logistic regression models showed that alcohol use among boys and girls was statistically significantly associated with study year, lower parental awareness where the child spends Saturday evenings, skipping the lessons, smoking, cannabis use and easy access to alcohol. Alcohol use was associated with lower socioeconomic status of the family and with unusual family structure among girls only. Compared to the first study year, alcohol use was lower in the last study year (OR = 0.52, 95% CI $0.43 - 0.64$ among boys, OR = 0.46, 95% CI $0.38 - 0.56$ among girls).

Conclusions:

In order to continue reduction of alcohol use among adolescents, the health promotion interventions should take into account the factors related to alcohol use in Estonia.

Key messages:

- Alcohol use decreased among adolescents in Estonia in 2003–2015.
- Alcohol use was associated with study year, family- and school-related factors, other risk behaviors and perceived alcohol availability.

Could Euroqol 5 Dimension questionnaire predict the characteristics of a hospitalization?

Claudia Cuccaro

C Cuccaro[1], *L Kundisova*[1], *N Nante*[1,2]
[1]Post Graduate School of Public Health, Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
[2]Department of Molecular and Developmental Medicine, University of Siena, Siena, Italy
Contact: claudia.cuccaro@student.unisi.it

Background:

Health related quality of life (HRQL) reflects how a particular state of health could influence individual wellbeing. Pathologies have a significant impact on the life, but the same conditions can be perceived differently so subjective evaluation by patient can be a valuable help to the doctors.

The aim of the study is to describe how the HRQL may correlate with some clinical conditions.

Methods:

A cross-sectional study was conducted in January-March 2019 in a private clinic. The Euroqol-5 Dimension (EQ-5D) questionnaire is a measure of quality of life to capture physical, mental and social functioning of patients and it was submitted at the time of admission. Examined variables were: age, sex, hospitalization period, EQ-5D index, EQ-5D dimensions (mobility, self-care, activity, pain, depression) and mini-mental state examination (MMSE). The sample was divided into subgroups for age (S1:<75 years, S2:>75) and for presence of problems (with or without). Statistical analysis was conducted using Stata 12.

Results:

A total of 59 patients were admitted, but only 33 (69.7% females) received the EQ-5D questionnaire. Average age was 80.2±12.3, higher for females (p = 0.02). The average length of stay was 12.7±9.4 days. The mean of EQ-5D index for the patients was 0.36±0.27 (S1:0.38±0.26; S2:0.27±0.3) and it did not seem to be significantly correlated with variables. The frequency of the EQ-5D dimensions problem stratified by age group was: mobility 96.97%(S1 21.21%, S2 75.76%), self-care 90.91%(S1 21.21%, S2 69.7%), usual activity 93.94%(S1 21.21%, S2 72.73%), pain 87.88%(S1 18.18%, S2 69.7%), depression 66.66%(S1 15.15%, S2 51.51%). The length of stay showed a significant correlation with pain(Spearman r = -0.45, p = 0.018) and depression(r = 0.46, p = 0.015).

Conclusions:

The majority of patients showed low level of EQ-5D index which is reflected in a low level of perceived HRQL. Pain and depression are the two dimensions that have shown a possible correlation.

Key messages:

- The EQ-5D index does not appear correlated to variables such as sex, age and length of stay.
- Depression and pain could be two important factors influencing a patient's admission and its length.

Implementation of a national epidemiological surveillance of prison suicide in France

Christine Chan Chee

C Chan Chee[1]
[1]Non-Communicable Diseases and Trauma Division, Santé Publique France, Saint Maurice, France
Contact: christine.chan-chee@santepubliquefrance.fr

Context:

Worldwide, suicide is a leading cause of death in prison. In France, suicide of prisoners accounts for more than 100 deaths per year representing about half of the total deaths in prison. Moreover, suicide rates in French prisons are seven times higher than in the community and are among the highest in Europe. Reducing prison suicide is a public health priority inscribed in a joint action plan of both the Ministries of health and of justice. In order to prevent this tragic loss of life, prison services and health services must collaborate for the monitoring and understanding of the risk factors involved. The aims of an epidemiologic surveillance of prison suicide are to gather information about the medical factors and factors related to prison environment, analyze them and eventually produce recommendations for prevention.

Methods:

After months of consultation between Santé publique France, different administrations and professionals working in prison, a common methodology was set up. As from January 2017, whenever a suicide or suspected death occurs in prison, the Direction of the Prison Administration (DAP) informs Santé publique France, who in turn sends to the medical practitioner in charge of the prison health services a questionnaire including the history before detention: morbidity, addiction, attempted suicide, and during detention: contact with prison health services, diagnosis and final contact prior to death. Each year, the DAP sends to Santé publique France the socio-demographic, administrative, judiciary and prison environmental data of the persons.

Results:

In 2017, data were collected for 106 suicides from 71 prisons: 95% males, 49% remand, 44% murder or sexual assault, median incarceration time 96 days. Questionnaires were returned from prison practitioners for 100 cases (94%): regular contact 83%, prior suicide attempt 23%.

Conclusions:

Feasibility of a prison suicide surveillance is only possible with the implication of both prison and health services.

Key messages:

- Reducing death by suicide in prison is a public health priority.
- Feasibility of a prison suicide surveillance is only possible with the implication of both prison and health services.

A six-years point prevalence survey of healthcare-associated infections in an Italian hospital

Andrea Gentili

A Gentili[1], *DI La Milia*[2], *D Vallone*[1], *M Di Pumpo*[1], *G Vangi*[2], *F Berloco*[2], *A Cambieri*[3], *G Damiani*[1,2], *P Laurenti*[1,2], *W Ricciardi*[1,2]
[1]Institute of Public Health, Section of Hygiene, Università Cattolica del Sacro Cuore, Rome, Italy
[2]Radioprotection and Hospital Hygiene Unit, Fondazione Agostino Gemelli IRCCS, Rome, Italy
[3]Medical Management, Fondazione Agostino Gemelli IRCCS, Rome, Italy
Contact: andreagentili1989@libero.it

Healthcare-Associated Infections (HAIs) are among the most serious public health problems in Europe representing the most frequent adverse event during care delivery. Despite their limitations, point prevalence surveys of HAIs are often preferred to prospective surveillance, since they provide a feasible estimate when resources are limited.

The aim of this study was to analyze the results of a six-years point prevalence survey of HAIs in a teaching acute care hospital in Italy and to investigate the main risk factors of HAIs in the acute-care hospital. A point prevalence survey to detect HAIs was carried out in Gemelli Hospital during the last 6 years, from 2013 to 2018. Inpatients of any age in Gemelli Hospital were eligible for inclusion. Patients in outpatient areas were excluded. HAIs were identified according to diagnosis guideline from ECDC in 2011. Statistically significant differences were tested through t-test and Chi-square test. Multi-variate analysis was performed to evaluate the impact of regressor factors for predict HAI's prevalence. The statistical significance level was set at $p < 0.05$. The point prevalence ranged from 3,16% in 2017 to 6,64% in 2013. Pneumonia and surgical site infections (SSI) were the most frequent HAIs during the 6 years, with a rate of 27,31% and 26,20%

respectively of all HAIs. The multiple logistic regression showed that length of stay at the moment of detection, urinary catheter, CVC and antibiotic therapy are useful to meaningfully predict HAI prevalence, with a regression coefficient (adjusted R2) of 0.2780.

Thanks to proper hospital policies, the point prevalence of HAIs does not seem to increase through the years, even though it is still too early to draw any conclusions. Pneumonia and SSI represented each one more than a quarter of all the HAIs, as reported also in literature. There is a strong association between length of stay at the moment of detection and HAIs but it is hard to understand which one is the cause of the other.

Key messages:

- Point prevalence from 2013 to 2018 seems to be stable. An accurate incidence survey is needed in order to identify the main risk factors of HAI and to realize more specific hospital programmes.
- Length of stay at the moment of detection is useful to meaningfully predict HAIs prevalence although the cause-and-effect relationship is still not clear.

Alcohol-related attendances in French emergency departments in 2017

Anne Fouillet

A Fouillet[1], *C Palle*[2], *S Charpentier*[3,4,5], *C Caserio-Schönemann*[1]
[1]Santé Publique France, Saint-Maurice, France
[2]Observatoire Français des Drogues et Toxicomanies (OFDT), Saint-Denis, France
[3]Département des Urgences, CHU Toulouse, Toulouse, France
[4]UMR 1027 INSERM, Toulouse, France
[5]Université Toulouse III – Paul Sabatier, Toulouse, France
Contact: anne.fouillet@santepubliquefrance.fr

Background:

France is one of the leading countries in terms of daily alcohol consumption per inhabitant. Alcohol is a major concern for emergency department (ED) since it accounts for a large part of their resources and increases behavior problems resulting in violence against staff. Individual information of French ED attendances registered in OSCOUR network are daily collected by Santé publique France, the French Public Health Agency. This study aims at describing alcohol-related ED attendances (ARA) in 2017 in France.

Methods:

The OSCOUR network included 677 ED in 2017 recording 92% of national attendances. ARA were identified through the main and associated medical diagnoses coded by physicians using ICD10. The study considered acute alcohol intoxication, dependence syndrome/withdrawal state, other mental disorders and intoxications due to alcohol, chronic complications and intentional self-poisoning by alcohol. The number of ARA was analyzed by age group, gender and region.

Results:

1.4% of total attendances were associated to alcohol consumption (202,184 attendances) in 2017. 68% of ARA were due to acute alcohol intoxication and 14% for dependence syndrome/withdrawal state. The highest proportions of ARA were observed for people aged 40-59 yo and 18-24 yo, particularly for women. Regions of North and West metropolitan France and La Réunion Island had the highest proportion of ARA among the total number of attendances.

Conclusions:

The part of ARA in France is consistent with figures provided in international studies using similar data. This proportion is similar with proportion of major public health issues like influenza, that represented 1% of the total ED attendances from November 2016 to February 2017 and reached 1.8% in January (month of the epidemic peak). Consequences of alcohol use represent a heavy burden for ED and the health system in France. This is all the more true as ARA are underestimated due to the low coding rate of associated medical diagnosis in ED.

Key messages:

- 1.4% of total French ED attendances were associated to alcohol consumption in 2017.
- This proportion is close to the proportion of influenza attendances in ED.

Evading the price: do French smokers go abroad to buy cheaper tobacco?

Raphaël Andler

R Andler[1], *R Guignard*[1], *A Lermenier-Jeannet*[2], *J-B Richard*[1], *A Pasquereau*[1], *G Quatremère*[1], *V Nguyen-Thanh*[1]
[1]Addictions, Santé Publique France, Saint-Maurice, France
[2]Observatoire Français des Drogues et des Toxicomanies, Paris, France
Contact: raphael.andler@santepubliquefrance.fr

Background:

In France, selling tobacco is strictly supervised and can only be done by official ‘‘tobacconists’’ making the price lever all the more efficient in preventing smoking. However, tobacco prices are rather heterogeneous in Europe and France is surrounded by countries with lower tobacco prices. The aim of our study was to investigate tobacco cross-border purchases by French smokers.

Methods:

Data come from the Santé publique France health Barometer, a national representative phone survey. In the 2014, 2017 and 2018 editions, respectively 4,721, 1,854 and 2,594 smokers where asked about their habits regarding purchasing tobacco.

Results:

In 2018, among adults, 77.8% of cigarette smokers (including RYO cigarettes) made their last purchase from an official French tobacconist and 16.4% made it in a neighboring country. Rates in bordering regions are drastically higher. These figures are quite similar to the ones observed in 2014 while tobacconist purchases had increased in 2017 and abroad purchases had decreased. In 2018, among adults, 44.3% of cigarette smokers stated they had bought tobacco abroad at least once during the past 12 months.

Conclusions:

Our study suggests that the frequency of cross border tobacco purchases by French smokers decreased between 2014 and 2017 while tobacco prices were not modified in France but increased between 2017 and 2018 as French tobacco prices went up. Our study also emphasises the fact that cross border purchases were a lot more common in bordering regions.

Key messages:

- Part of French smokers avoid price increases by purchasing tobacco abroad.
- This public health policy measure could be more efficient if tobacco prices were aligned in Europe.

General practitioners, pregnancy and addictions in France in 2015

Raphaël Andler

R Andler[1], *C Cogordan*[1], *A Pasquereau*[1], *J-F Buyck*[2], *V Nguyen-Thanh*[1]
[1]Addictions, Santé Publique France, Saint-Maurice, France
[2]Observatoire Régional de La Santé Des Pays de La Loire, Nantes, France
Contact: raphael.andler@santepubliquefrance.fr

Background:

Tobacco smoking and alcohol drinking during pregnancy result in serious health hazard for both the baby and the mother. In France, about 17% of pregnant women smoke and 20% consume alcohol. General practitioners (GPs) can have an active role in preventing those behaviors as they often interact with pregnant patients: one quarter of French pregnant women have had at least one antenatal visit with a GP. The aim of our study is to describe French GPs’ practices (screening and counseling) toward pregnant patients regarding tobacco smoking and alcohol drinking.

Methods:

In 2015, a telephone survey was set based on a stratified random sampling of metropolitan France GPs. A representative sample of 1,414 French GPs completed the study.

Results:

Screening for alcohol consumption at least once for every patient was done by 61% of GPs and for smoking by 82% of

GPs. Counselling to quit alcohol consumption was done by 77% of GPs while counselling to quit smoking was done by about 90% of them. GPs' practices were significantly better among those who had more recent ongoing training. Regular drinkers GPs were less likely to systematically screen for alcohol use and GPs' alcohol use frequency was adversely related to recommending quitting. Current and former smokers GPs were less likely to recommend quitting to pregnant patients smoking over 5 cigarettes per day.

Conclusions:

Screening for alcohol use and smoking during pregnancy is not yet systematic among GPs in France. GPs' prevention role with pregnant patients could be emphasized, potentially through initial and ongoing trainings adaptation. Besides, as regular alcohol use and smoking are related to unwanted practices, prevention for the benefit of GPs could be even more fruitful.

Key messages:

- Screening for alcohol use and smoking during pregnancy is not systematically done by French GPs.
- GPs' prevention role with pregnant patients could be emphasized, potentially through initial and ongoing trainings adaptation.

Tobacco smoking and binge drinking among university students in three European countries, 2009-2017

Marie-Pierre Tavolacci

M Tavolacci[1], S De Bruyn[2], C Van der Heijde[3], P Vonk[3], J Ladner[4], G Van Hal[5]

[1]Clinical Investigation Center 1404 Inserm1073, Rouen University Hospital, Normandie University, Rouen, France

[2]Department of Sociology, University of Antwerp, Antwerp, Belgium

[3]Student Health Service, University of Amsterdam, Amsterdam, Netherlands

[4]Dpt of Epidemiology and Public Health, INSERM 1073, Rouen University Hospital, Normandie University, Rouen, France

[5]Social Epidemiology and Health Policy, University of Antwerp, Antwerp, Belgium

Contact: Marie-Pierre.Tavolacci@chu-rouen.fr

Background:

Attention is needed on students as high levels of substance use are often part of the university experience. The aim of the study is to identify the trend of tobacco smoking and binge drinking among university students (US) of Belgium, France and the Netherlands over a 9 years period.

Methods:

Three repeated cross-sectional studies in US were performed in 2009-10, 2012-13 and 2016-17 in university of Antwerp (Belgium), Amsterdam (the Netherlands) and Rouen (France). US between 18 and 25 voluntarily filled out a self-administered anonymous questionnaire. The socio-demographic characteristics (age, gender, curriculum, job and accommodation) of the US were collected. Tobacco smoking and binge drinking in the previous 12 months were also collected. The trend test of Cochran-Armitage was used for comparisons.

Results:

In 2010, 1388 US were included in Antwerp, 1907 in Amsterdam, and 1137 in Rouen. In 2013, 1665 US were included in Antwerp, 3590 in Amsterdam, and 1488 in Rouen. In 2016, 2347 US were included in Antwerp, 4157 in Amsterdam, and 1011 in Rouen. Female gender was 63.4% in Antwerp, 68.7% in Amsterdam and 65.4% in Rouen. The prevalence of tobacco smoking was respectively in 2010, 2013 and 2016: in Antwerp: 31.0%, 33.5% and 27.6% ($p = 0.008$); in Amsterdam: 13.7%, 16.5% and 17.0% ($p = 0.003$); in Rouen: 21.3%, 23.7% and 23.5% ($p = 0.21$). The prevalence of binge drinking (more than once a month) was respectively in 2010, 2013 and 2016: in Antwerp: 16.2%, 12.3% and 16.7% ($p = 0.30$); in Amsterdam: 26.5%, 27.4% and 26.5% ($p = 0.82$); in Rouen: 8.6%, 16.6% and 7.1% ($p = 0.44$).

Conclusions:

Risk behaviours as tobacco smoking and binge drinking in US show a different prevalence according to country. Tobacco smoking decreases in two countries and frequent binge drinking did not change during the 9 years period. Further analyses need to be conducted taking into account the curriculum and the socio-demographic characteristics.

Key messages:

- Risk behaviours as tobacco smoking and binge drinking in university students show a different prevalence according to the European country.
- Binge drinking does not worsen for 9 years among university students.

Who does use ENDS in Russia? Results from Russian tobacco control policy evaluation survey EPOCHA-RF

Marine Gambaryan

MH Gambaryan[1], AM Kalinina[1], MV Popovich[1], ML Starovoytov[1], OM Drapkina[1], SA Boytsov[2]

[1]National Medical Research Centre for Preventive Medicine of the MoH, Moscow, Russia

[2]National Medical Research Centre for Cardiology of the MoH, Moscow, Russia

Contact: mgambar@mgnicpm.com

Background:

Electronic Nicotine Delivery Systems (ENDS) become popular in Russia. Still little is known about use of these products.

Aim:

To assess patterns of active and passive exposure to ENDS in Russian population.

Methods:

Data from Russian tobacco control policy evaluation survey (2017-2018) are analysed, conducted on the basis of multistage territorial random sample of 11625 respondents: 6569 smokers, 2377 former smokers and 2679 never smokers 18years and older in 10 Russian Federal subjects.

Results:

38.8% of the respondents were familiar with ENDS, with the highest proportion in the youngest age group (18-24): 53.8%($p<.0001$). 9.3%had tried ENDS, among 18-24 years old - those were 23.5%($p<.0001$). The amount was significantly higher among recent quitters (in last 3years)-17.2%, and current smokers-13% compared with former (quitters for more than 3years) and never smokers. Of those 26.4% used ENDS regularly-with highest proportion among 18-24years old (29.1%), and current smokers (27.1%). This comprises 2.5% of respondents as regular ENDS users, and 6.8%-among the youngest group. Half of the smokers had tried to quit by means of ENDS, of those 69% failed to quit smoking, and 79% could neither give up smoking nor ENDS. However, only 18% ENDS users agreed that e-cigarettes cause addiction, and 37% even denied the fact. Those were mostly the youngest respondents (45%). Vaping was not allowed at homes of 67.4%respondents, at workplaces-of 65.6%. 14% of respondents had witnessed vaping at workplaces, 55.8% in public places, 20.3% cafes, restaurants and bars. 51.4% had been exposed to secondhand aerosols of ENDS and 73.2%-among 18-24years olds. 37%found exposure to the aerosols annoying, with significant differences between never/former smokers (58% and 50.3%) and recent quitters and current smokers (39.3% and 29.2%).

Conclusions:

Young people are mostly exposed to ENDS in Russia. Strong legislation should be considered to regulate ENDS and protect people from their exposure.

Key messages:

- Electronic cigarettes are mostly prevalent among the youngest age groups, current smokers and recent quitters in Russia.
- ENDS do not help smokers to quit: vast majority of smokers who used ENDS for this purpose failed to give up both smoking and electronic cigarettes.

ENDS - a growing threat: results from Russian tobacco control policy evaluation survey EPOCHA-RF

Marine Gambaryan

MH Gambaryan[1], *AM Kalinina*[1], *MV Popovich*[1], *ML Starovoytov*[1], *OM Drapkina*[1], *SA Boytsov*[2]
[1]National Medical Research Centre for Preventive Medicine of the MoH, Moscow, Russia
[2]National Medical Research Centre for Cardiology of the MoH, Moscow, Russia
Contact: mgambar@mgnicpm.com

Background:

Electronic nicotine delivery systems (ENDS) including heated tobacco products not yet legally regulated are more and more imposed over the Russian population. Still very little is known about these products.

Aim:

To assess the exposure of Russian population to advertisement, promotion, of ENDS, and its attitudes and beliefs regarding these products.

Methods:

Data from Russian tobacco control policy evaluation survey (2017-2018) are analysed which used a systematic stratified multistage random sampling based on territorial household principle, representing the adult population (18+) of Russia in 10 Federal subjects. 20380 randomly selected respondents were interviewed and a stratified sample (n = 11625) of smokers (n = 6569), former smokers (n = 2377) and never smokers (n = 2679) participated in the survey.

Results:

In past 6 months 15.7% of the respondents were exposed to promotion of ENDS via internet, 14%-via social networks and 13.4% at the points of sale. Remarkably the youngest age group (18-24) was significantly more exposed to advertisement and promotion of ENDS from all sources than the rest of age groups: 32.6%, 32.3% and 24.3% respectively (p<.0001).

48% of respondents believe that secondhand vape of e-cigarettes is harmful for health of people, with significant differences among current smokers (40%), recent quitters (53%), former smokers (60%) and never smokers (66%). Majority agreed that it is necessary to regulate allowed amounts of nicotine in e-liquids (54%), to ban vaping in public places where tobacco smoking is banned (59.2%), ban the sales of these products to minors (68%), and the use of e-cigarettes by those (71.2%). 61.5% support the need for ban of all forms of advertisement, marketing and promotion of ENDS.

Conclusions:

ENDS present a real threat for Russian tobacco control policy achievements. The findings will be used to support new strong legislation to regulate ENDS in Russia.

Key messages:

- Young people much more than the others are targeted with advertisement and promotion of ENDS.
- ENDS present a real threat for Russian tobacco control policy and should be legally regulated like any tobacco products.

Tetralogy of Fallot in infants less than one year old in the Valencia Region (Spain)

Clara Cavero Carbonell

C Cavero Carbonell[1], *L Barrachina Bonet*[1], *T Fernández Rojas*[1], *S Moreno Marro*[1], *L Páramo Rodríguez*[1], *S Guardiola-Vilarroig*[1], *O Zurriaga*[1]
[1]Rare Diseases Joint Research Unit. FISABIO-UVEG, FISABIO, Valencia, Spain
Contact: cavero_cla@gva.es

Background:

Tetralogy of Fallot (TF) is a rare disease characterized by the presence of 4 congenital heart defects (CHD). Objective: to describe the temporal trend and distribution of the TF in the Valencia Region (VR), in less than one year old, during the period 2007-2016.

Methods:

Live births, stillbirths and termination of pregnancy due to fetal anomaly (TOPFA) between 2007-2016 with TF (code Q21.3 of the ICD10-BPA) were selected from the Congenital Anomalies (CA) population-based Registry of VR. The cases were confirmed through the review of clinical documentation. The prevalence of 10000 births with 95% confidence intervals (95%CI) was calculated for the period and for each year, and a descriptive analysis of sociodemographic and clinical variables was made.

Results:

146 cases were identified (45.2% male, 31.5% female and 23.3% unknown), 89.0% were simple pregnancies and 54.8% were diagnosed prenatally. The overall prevalence of TF was 3.0/10000 births (95%CI: 2.5-3.5), being 2015 the year with the highest prevalence (4.3/10000 births) and 2011 with the lowest (1.8/10000 births). These changes were mainly due to the increase and decrease in the number of TOPFA respectively. 74.7% were live births, 22.6% TOPFA and 2.7% stillbirths. The prevalence in live births was 2.2/10000 births (95%CI: 1.8-2.6) and in TOPFA it was 0.7/10000 births (95%CI: 0.4-0.9), identifying an increasing trend during the period in the last one. 11.0% of live births died during the first year of life. 45.9% of the cases had another CA associated with the TF, being CHD in 52.7% of cases. 66.4% of the mothers were over 30 years of age, being the most frequent those between 30-34 years (30.1%).

Conclusions:

The prevalence obtained in the VR was lower than that of EUROCAT 3.5/10000 births (95%CI: 3.3-3.6) during the same period. EUROCAT has also identified the difference between the prevalence in live births (2.9 (95%CI: 2.8-3.0)) and TOPFA (0.5 (95%CI: 0.5-0.6)), and the increasing trend in the last one.

Key messages:

- The prevalence of Tetralogy of Fallot obtained in the VR was lower than that of EUROCAT (European network of population-based registries for the epidemiologic surveillance of congenital anomalies).
- EUROCAT has also identified the difference between the prevalence of Tetralogy of Fallot in live births and termination of pregnancy due to fetal anomaly, and the increasing trend in the last one.

Validity of sources of information used for the identification of Wilson's disease in the Registries

Clara Cavero Carbonell

C Cavero Carbonell[1], *S Moreno Marro*[1], *L Barrachina Bonet*[1], *L Páramo Rodríguez*[1], *S Guardiola Vilarroig*[1], *O Zurriaga*[1], *Regional Population-based Registries of Rare Diseases*[2], *Rare Diseases Research Institute*[3]
[1]Rare Diseases Joint Research Unit. FISABIO-UVEG, FISABIO, Valencia, Spain
[2]Health Departments, Spain, Spain
[3]Institute of Health Carlos III, Madrid, Spain
Contact: cavero_cla@gva.es

Background:

Objective: to determine the sources of information used by the Regional Population-based Registries of Rare Diseases (RD) (RRD) for the identification of the Wilson's Disease (WD) during the period 2010-2015, and to evaluate the validity of these sources.

Methods:

A cross-sectional study was conducted involving 14 different Spanish Regions and the RD Research Institute. Possible cases with WD diagnosis included in RRD were identified with codes 275.1 in ICD9CM or E83.0 in ICD10 (unspecific codes referring to 'Disorders of copper metabolism'), and they were confirmed or not through a validation process in which clinical documentation was reviewed. Each Region sent their database to the coordinator (Valencian Region), which calculated the positive predictive value (PPV) for each source used individually and for the combination of two sources.

Results:

995 records were identified and reviewed. 444 were confirmed, 475 were discarded and 76 were considered as possible. The PPV for all sources was 44.6%. The Hospital Discharge

Database (CMBD) stands out as the main source of detection of possible cases with a PPV of 42.1%, followed by the Orphan Drugs Registry (ODR) with a higher PPV (80.8%) and by the Mortality Registry with a lower PPV (16.7%). The Clinical History of Primary Care (PC) obtained a VPP of 55.8%, but was only used in three Spanish Regions. The PPV for the combinations of two sources of information was 94.5% for the CMBD with the ODR, 91.5% for the ODR with PC and 73.9% for the CMBD with PC.

Conclusions:

Although CMBD has been the most widely used source, its PPV is not the highest. However, the ODR is the source with the highest PPV. The introduction in 2016 in the CMBD of the Spanish version of the ICD10 which includes a specific code for the WD (E83.01) is expected to improve this value. Cases identified by both (CMBD and ODR) may be automatically validated due to the high PPV obtained.

Funding: Fundació Per Amor a l'Art and Obra Social ''la Caixa''

Key messages:

- Wilson's disease is one of the 10 Rare Diseases included in the Spanish Registry of Rare Diseases but the validity of sources of information hadn't been studied.
- The introduction in 2016 in the Spanish Hospital Discharge Database of the Spanish version of the ICD10 will improve the validity of the sources of information used by the Registries of Rare Diseases.

Use and perceptions of electronic cigarette by the adult population in France in 2017

Guillemette Quatremère

G Quatremère[1], A Pasquereau[1], R Guignard[1], R Andler[1], JB Richard[1], V Nguyen Thanh[1]

[1]Addictions Unit, Santé Publique France, Saint-Maurice, France

Contact: guillemette.quatremere@santepubliquefrance.fr

Background:

E-cigarette (EC) use is controversial because its benefit-risk ratio is still unclear. Since its introduction on the French market at the beginning of the 2010's, French health authorities have published cautious recommendations. The study aims at describing uses and perceptions about EC among the adult population.

Methods:

Santé Publique France's Health Barometer, the French national public health agency, is a cross-sectional random survey conducted annually by phone, on a representative sample of the population aged 18-75 y/o in Mainland France. Descriptive analysis and logistic regressions were performed to analyze data collected from the 25,319 respondents of the 2017 edition.

Results:

In 2017 in Mainland France, 3.8% of the population used an EC, 2.7% on a daily basis. Among EC daily users, 60.4% were men, 57.9% had a bachelor degree or higher qualifications. Less than 1% of EC users were never-smokers, 50.3% were daily or occasional smokers, 49.5% were former smokers. The number of daily ex-smokers who did quit smoking (> = 6 months) and believed that vaping has helped them to, was estimated to be 700,000 since EC has been available in France. EC was perceived as equally or more harmful than regular cigarette by half of the population (51.5%), a proportion that has increased since 2014 (43.4%). Daily smokers perceived EC as more harmful, while being an EC user from high socioeconomic status was associated with the perception that EC is less harmful. The bans on EC in places where smoking is prohibited and on sales of EC to minors (<18 y/o) were appreciated by 66.9% and 77.5%, respectively.

Conclusions:

These results show that in France, EC is strongly related to current or past smoking habits. A significant number of ex-smokers believe that EC has helped them quit smoking. Sociodemographic differences in the perception of EC harmfulness suggest social inequalities in access to information.

Key messages:

- Electronic cigarette users in France are few and most of them are smokers or former smokers.
- The perception of electronic cigarettes harmfulness depends on sociodemographic and smoking status.

Challenges of a French Hospital Discharge algorithm to detect non-accidental paediatric burns

Coralie Hermetet

C Hermetet[1,2], E Laurent[1,2], Y El Allali[3], C Gaborit[1], A-I Lecuyer[1], A Urvois-Grange[4], P Saint-Martin[5], M Biotteau[1,6], A Le Touze[7], L Grammatico-Guillon[1,8]

[8]University of Tours, Tours, France

Contact: coralie.hermetet@etu.univ-tours.fr

Background:

Child maltreatment includes physical, psychological, sexual abuse and acts of neglect. Among the resulting non-accidental injuries, burns are responsible for an important morbi-mortality. The main objective was to build a detection algorithm of non-accidental paediatric burns (NAB), using ICD-10 codes in the hospital resumes from the French Hospital Discharge Database (HDD).

Methods:

Children aged 0 to 16 years old hospitalised at the University Hospital of Tours from 2012 to 2017 with a coded burn were included. ''Probable'' or ''possible'' HDD cases of NAB were defined based on specific ICD-10 codes during the inclusion stay or the previous year. A chart review was performed on all the HDD cases and HDD non cases matched on sex and age with a 1:2 ratio. Performance parameters were estimated for three clinical definitions of suspected child maltreatment: excluding neglect, including neglect with restriction then broad definition. For clinical cases, report to the judicial authority (RJA) or worrying information (WI) was searched.

Results:

Among the 253 included children, 83 ''probable'' cases and 153 non cases were analysed. Sensitivity varied from 48% (95%CI [36-60]) to 90% [55-100] when excluding neglect, specificity from 70% [63;77] to 68% [61;74]. The positive and negative likelihood ratios varied respectively from 1,6 [1,2;2,3] to 2,8 [2,1;3,7] and from 0,7 [0,6;0,9] to 0,1 [0,0;0,9]. The proportion of clinical cases with no RJA/WI without reason varied from 0 (when excluding neglect) to > 85% (with broadest definition); all corresponded to a possible isolated neglect.

Conclusions:

The performances of the algorithm varied tremendously according to the clinical definition level of child maltreatment. Neglect is obviously difficult to clinically detect. Training for healthcare professionals and qualitative studies on obstacles to RJA/WI should be added to this work.

Key messages:

- The performances of an algorithm to detect non-accidental pediatric burns (maltreatment) using the French hospital discharge database dropped when including neglect, difficult to diagnose clinically.
- Training for healthcare professionals and qualitative studies on obstacles to the judicial authority (RJA) or worrying information (WI) should be added to this diagnostic study.

Autochthonous chikungunya and dengue fever outbreak in Mainland France, 2010-2018

Florian Franke

F Franke[1], S Giron[1], A Cochet[2], C Jeannin[3], I Leparc-Goffart[4], H de Valk[5], F Jourdain[5], X de Lamballerie[6], G L'Ambert[3], MC Paty[5]

[6]UMR Émergence des Pathologies Virales (UMR EPV), Université d'Aix-Marseille, IRD 190, Inserm 1207, EHESP, IHU Méditerranée Infection, Marseille, France
Contact: florian.franke@santepubliquefrance.fr

Background:

Aedes albopictus, vector of dengue and chikungunya viruses, is implanted in mainland France, exposing to the risk of autochthonous transmission. Since 2006, epidemiological and entomological surveillance activities aim to prevent or limit the occurrence of autochthonous cases. We aimed to describe episodes of transmission and control measures implemented in order to reflect on surveillance activities.

Methods:

We reviewed all publications and documents produced on autochthonous transmission episodes in France and surveillance protocols. We reviewed surveillance activities, investigation methods and control measures implemented.

Results:

Between 2010 and 2018, eight episodes of autochthonous dengue fever transmission and three of chikungunya were recorded in mainland France. All of them occurred in the South east of France, between July and October, when vector density was the highest. Transmission areas were limited to single domestic houses located in discontinuous urban areas. Only two episodes happened in two distinct areas. Chikungunya episodes led to 31 cases and dengue fever episodes to 23 cases. Most cases were identified by door-to-door investigations set-up in transmission areas. We isolated serotypes 1 and 2 for dengue and East Central South Africa lineage for chikungunya in autochthonous cases. Adulticide vector control measures were effective in controlling transmission.

Seven episodes of transmission were due to failure in identifying primary imported cases. Four episodes occurred because of the absence or the lack of vector controls measures around primary imported cases.

Conclusions:

Surveillance activities, and autochthonous cases investigations, were effective in limiting the extent of transmission, but were highly demanding for surveillance actors. Identified causes of transmission highlight the need of regular awareness campaigns targeting physicians and biologists.

Key messages:

- Effectiveness of the surveillance system of dengue, chikungunya and zika viruses, and autochthonous cases investigations.
- Needs of awareness and training courses targeting health professionals to the risk represented by these viruses.

Self-rated health and attitude to cardiovascular prevention in male population in Russia/Siberia

Dmitriy Panov

V Gafarov[1], E Gromova[1], D Panov[1], I Gagulin[1], A Gafarova[1]
[1]Collaborative Laboratory of Cardiovascular Diseases Epidemiology, Institute of Internal and Preventive Medicine, Institute of Cytology and Genetics SB RAS, Novosibirsk, Russia
Contact: dimitriy2004@inbox.ru

Objective:

To establish the dynamics of the relationship to the prevention of cardiovascular disease, awareness, attitude to their health for 32 years (1984 -2016 yy.) In the open population among males 25-44 years in Russia / Siberia (Novosibirsk).

Methods:

Within the framework of WHO's MONICA-psychosocial program random representative samples of the male population aged 25-64 years in Novosibirsk were examined: 1984-85 (n = 753); 1988-89 (n = 739); 1994-95 (n = 657); 2013-2016 (n = 427), used the 'Knowledge and attitude to one's health' scale.

Results:

During the observation period from 1984 to 2016, the number of men 25-44 years old believed that they are 'healthy' or have 'good health', but at the same time, the number of those who believe that their health they care clearly is not enough. Most men were of the opinion that a healthy person can develop a serious illness within the next 5-10 years. The number of those who believed that preventive measures will help to avoid some serious diseases has increased. Men began to stop working more often, if they did not feel well, the number of those who reduced their work and had a rest increased. The number of men has grown, who believe that a preventive health check is useful and who has started to observe proper nutrition. The number of men who smoke has decreased.

Conclusions:

The dynamics of attitude towards the prevention of cardiovascular diseases, awareness, attitude to their health for 32 years indicates that at present health has become a value dominant due to a new understanding of the importance of health in terms of adapting to modern economic requirements.

Key messages:

- The purpose of our study was to study the dynamics of awareness and attitudes towards one's health for 32 years (from 1984 to 2016) in an open population of working-age men 25–44 years old.
- The purpose of our study was to study the dynamics of awareness and attitudes towards one's health for 32 years (from 1984 to 2016) in an open population of working-age men 25–44 years old.

Long-term trends in adherence to prevention in female population aged 25-44 years in Russia/Siberia

Dmitriy Panov

V Gafarov[1], D Panov[1], E Gromova[1], I Gagulin[1], A Gafarova[1]
[1]Collaborative Laboratory of Cardiovascular Diseases Epidemiology, Institute of Internal and Preventive Medicine, Institute of Cytology and Genetics SB RAS, Novosibirsk, Russia
Contact: dimitriy2004@inbox.ru

Objective:

To determine the 23-year trends 1994-2016 yy of adherence towards cardiovascular diseases prevention, behavioral characteristics and awareness about the health in general female population aged 25-44 years in Russia / Siberia.

Methods:

Under the third screening of the WHO program MONICA and sub-program 'MONICA-psychosocial' (MOPSY) random representative sample of women aged 25-64 years (n = 870) were surveyed in Novosibirsk in 1994; 284 persons in group 25-44y. In 2016 within the framework of the screening studies covered by state task reg.# 01201282292 a random representative sample of women aged 25-44 years was examined in the same district of Novosibirsk (n = 540). Questionnaire MOPSY 'Awareness and attitude towards the health' was used to estimate adherence towards cardiovascular diseases prevention, behavioral characteristics and awareness about the health.

Results:

The analysis showed there is a positive trend in self-rated health in female population aged 25-44 years. Despite this 50% of women rate their health negatively and 96% consider the existence of high chance to be ill with serious disease within next 5-10 years. Majority of women believed in the possibilities of modern medicine for the prevention of heart disease but there is extremely low level of healthcare utilization as prevention measure and it doesn't exceed 10% in those women ($p < 0.05$). There is a growth of job stress levels and upward trends in family status changes over 23 years in an open population of women aged 25-44 years. Some changes in behavioral status were found over 1994-2016 yy: increased share of people quit smoking and doing regular physical exercises, improved diet behavior.

Conclusions:

We showed a positive trend in CVD risk factors prevention in women 25-44y. In spite of this, half of the women negatively evaluate their health and using of healthcare resources is deficient. There are adverse changes in the social gradient over the follow-up period.

Key messages:

- The purpose of this survey was to study the trends in awareness and attitudes towards cardiovascular prevention over 28 years (from 1988 to 2016) in an open female population of 25-44 years old.
- The purpose of this survey was to study the trends in awareness and attitudes towards cardiovascular prevention over 28 years (from 1988 to 2016) in an open female population of 25-44 years old.

West Nile virus infections in France, July to November 2018

Lauriane Ramalli

Contact: lauriane.ramalli@santepubliquefrance.fr

In July 2018, one autochthonous case of West Nile virus (WNV) infection was identified in Nice, Provence-Alpes-Côte d'Azur (Paca). We investigated to determine the potential place of infection and the extent of viral circulation in the area, in order to guide control and preventive measures. In affected areas, we raised awareness of health professionals on WNV infections, substance of human origin safety relied on nucleic acid testing for WNV and on deferral of blood donors indicating minimum one night of stay in the areas for 28 days. Equine, wild bird and entomologic surveillance activities were reinforced. The human arboviruses national reference laboratory (NRL) retrospectively tested samples from hospitalized individuals from June 1st with meningitis and encephalitis around Nice. We tested negative suspected autochthonous cases of chikungunya and dengue infections notified since July in Paca and presenting WNV compatible symptoms. Measures were adapted along identification of additional cases.

We identified 27 autochthonous cases, with onset of symptoms between July 7th and November 12th: 24 in Paca, 2 in Corsica and 1 in Occitanie. Seven cases presented neuroinvasives symptoms, 18 flu-like symptoms and 2 were asymptomatic. One blood donation and 2 organs tested positive for WNV. The animal NRL identified 13 equine cases (1 in Paca, 5 in Corsica and 7 in Occitanie) and 4 infected raptors with nervous symptoms (3 in Paca and 1 in Corsica). Genomic characterization of the virus identified a strain belonging to the lineage 2 among 2 raptors. No virus was found in mosquitoes captured in affected areas.

Since 2000, six episodes of WNV transmission were reported in France but none with this extent. For the first time, the lineage 2, circulating in Italy and other European countries, was isolated in France which might be changing epidemiological situation. Therefore, surveillance activities should be revised in order to promptly secure blood products.

Key messages:

- We describe the most important episode of West Nile Virus transmission identified in humans in France.
- In 2018, West Nile virus lineage 2 was isolated for the first time in France which might change the epidemiological situation in the country.

Out of country tobacco purchases decrease despite a price increase and plain packaging in France.

Ramchandar Gomajee

F El-Khoury[1], R Gomajee[1], H Torregrossa[1], C Bolze[1], M Melchior[1]
[1]Social Epidemiology Research Team, Sorbonne University, Pierre Louis Institute of Epidemiology and Public Health, Paris, France
Contact: ramchandar.gomajee@inserm.fr

Background:

The introduction of new anti-tobacco measures in France (plain tobacco packaging, higher prices) might encourage smokers to buy their tobacco from other sources than tobacco shops. We examine whether these measures increased the likelihood of smokers purchasing tobacco abroad, depending on their driving distance from the border of a neighboring country with lower tobacco prices.

Methods:

DePICT is a two-wave cross sectional national telephone survey examining the French population tobacco-related perceptions and behaviors before and after the introduction of the new measures in 2017. Smokers were asked whether they bought tobacco from abroad in the last 12 months. Shortest driving distances to neighboring countries' border were calculated using Google Maps (<100 Km, 100-200 Km, 200-300 Km, >300 Km and Ile-de-France (IDF)). Data was weighted to be representative of the population living in France. Multivariate regressions, adjusted on socio-demographic characteristics as well as substance use behaviors, were carried out.

Results:

Compared to smokers living at more than 300 Km from a border, those living near a border, and in IDF were significantly more likely to have bought tobacco from abroad (<100 Km: ORadjusted = 3.98; 100-200 Km: ORadjusted = 2.04; 200-300 Km: ORadjusted = 1.47; IDF: ORadjusted = 1.32). Smokers in wave 2 (n = 929) were significantly less likely than those in wave 1 (n = 1238) to have bought tobacco abroad (ORadjusted = 0.81 [95% CI: 0.69-0.96]). It was mainly smokers who were in a driving distances of 100-200 Km, and 200-300 Km who were significantly less likely to buy abroad across the 2 waves (respectively ORadjusted = 0.56 [95% CI: 0.34-0.92] and ORadjusted = 0.50 [95% CI: 0.27-0.92]). Supplementary analyses showed that it was mainly for men and smokers born in France that the decrease was significant.

Conclusions:

Our results suggest that the new anti-tobacco measures did not increase out of country tobacco purchases by smokers.

Key messages:

- The introduction of new anti-smoking measures (increase in price, plain tobacco packaging) did not increase the likelihood of smokers purchasing tobacco from abroad.
- It was mainly male smokers and smokers born in France that had a decreased likelihood of purchasing tobacco from abroad after the introduction of new anti-tobacco measures.

The ICHOM standard set for patient reported outcomes in diabetes

Fabrizio Carinci

F Carinci[1], J Nano[2,3], O Okunade[3], S Whittaker[3], M Walbaum[3], M Massi Benedetti[4]
[1]Department of Statistical Sciences, University of Bologna, Bologna, Italy
[2]Institute of Epidemiology, Helmholtz Zentrum, Münich, Germany
[3]International Consortium for Health Outcomes Measurement, London, UK
[4]Hub for International health ReSearch, Perugia, Italy

Contact: fabrizio.carinci@unibo.it

Background:

Between 2017-2018, the International Consortium for Health Outcomes Measurement (ICHOM) conducted a targeted study to deliver a standard set of outcome measures in diabetes, including patient reported outcomes. Compared to other conditions, the study faced the challenge of a complex data collection in a highly prevalent multifactorial chronic disease.

Methods:

We conducted a structured systematic review of outcome measures focusing on adults with either Type 1 or Type 2 diabetes, followed by a consensus-driven modified Delphi panel including a multidisciplinary group of academics, health professionals and patient representatives. The applicability of the standard set was explored by collecting external feedback from patients and health professionals worldwide.

Results:

The panel identified an essential set of case-mix characteristics and clinical outcomes, including factors related to diabetes control, acute events, chronic complications, health services and survival that can be regularly measured using routine data and ad hoc data collection. Three validated instruments were recommended for ad-hoc data collection of patient-reported outcomes: the "WHO-5" for psychological wellbeing, the "PAID" for diabetes distress and the "PHQ-9" for depression. The feedback received from members of the panel highlighted substantial challenges with regards to the applicability of the approach at a large scale.

Conclusions:

The standard set recommended for use to monitor, benchmark and improve diabetes care has received strong support from stakeholders involved in the process worldwide. However, substantial challenges remain on how to organize a systematic data collection worldwide, with implications on policy and practice that can equally apply across all areas of chronic care. Prioritization of selected targets may be useful to achieve practical results in the immediate future.

Key messages:

- A standard set for the data collection of person-centred outcomes in diabetes has been successfully delivered by ICHOM, including case-mix characteristics, clinical and person reported outcomes.
- The feedback received from a range of stakeholders highlight implications for policy and practice in the data collection of PROMs for person-centred chronic disease monitoring.

Singular death-causes contribution to temporal trend-shifts of its major causes in Spain, 1975-2016

Lluís Cirera

L Cirera[1,2,3], M Ballesta[1,3], D Salmerón[3,2]

Contact: lluis.cirera@carm.es

Background:

Mortality is the arrow of aggregated individual's life style of living beside the national public health and health care system outcomes. The contribution of specified death-causes to the temporal evolution of its great cause, is targeting the community framework for public health action reduction.

Objective:

To assess yearly contribution of specified death-causes to temporal trend-shifts of its major death- cause in Spain, 1975 to 2016.

Methods:

causes of death were selected based on magnitude and relevance in public health. Coding-linkage was established between ICD-9 to 10 revisions. Annual-standardized rates were calculated by the direct method according to the European Standard Population from 1975 to 2016. Linear trend period changes were measured through Joinpoint regression models as annual percentage change (APC) and 95% confidence intervals (CI). Joinpoint v4.0.4 and R v3.2.2 software were used at $p < 0.05$ for statistically significance level.

Results:

Neoplasm rates have been going downwards (extreme years came from 162.2/100,000 inhabitants to 145.5) on ending year-periods of 1995-2008-2016. Lung and colorectal cancers replicated neoplasm shape in lower magnitudes. Cardiovascular displayed two decreasing trajectories in 1975-1993 and 1993-2013, and a last flat stage in 2013-2016, while cardiac ischaemia and ictus crossed their trend periods. Ictus has evolved quite in parallel to cardiovascular disease. Influenza and pneumonia conformed a close profile to respiratory great cause contribution, in different periods: 1975-1988 [-8.03% (-9.08, -6.96%)] and 1988-2016 [-2.38% (-2.85, -1.91%)]. Traffic accidents have been modulating external causes dropping shape with a nonsignificant slope period- trend in the 1994-2001 years.

Conclusions:

The contribution of any singular causes of death into temporal development of its great causes, is a plausible tool for public health surveillance issues addressed to action.

Key messages:

- The great cause of death in temporal evolution is a moving aggregate result of its singular causes of death components over last time.
- Inflection-trends years-period of death causes are a plausible tool to public health surveillance.

How to estimate mild Traumatic Brain Injury Incidence? The interest of Emergency Departments data

Virginie Bourdin

V Bourdin[1], L Manitchoko[1], P Azouvi[2,3], R Hellmann[4], L Josseran[1,3]

[1]Public Health Department, APHP, Raymond-Poincaré Hospital, Garches, France

[2]Physical Medicine and Rehabilitation Department, APHP, Raymond-Poincaré Hospital, Garches, France

[3]HANDIReSP, EA4047, UFR Simone Veil, Versailles Saint-Quentin University, Montigny-Le-Bretonneux, France

[4]Direction de l'offre de Soins, Agence Régionale de Santé, Ile de France, Paris, France

Contact: virginie.dufauret@gmail.com

Background:

Traumatic brain injury (TBI) is a major public health issue, with a significant socio-economic burden. In France, very little is known about TBI epidemiology, and the TBI population is mainly described via studies carried out on the most severe patients. A large number of studies showed that a significant proportion of patients suffer from long-term disability after mild TBI (mTBI). This Post-Concussive Syndrome (PCS) remains poorly known by health professionals. Identifying early prognostic factors for the development of PCS is therefore essential, since it can ensure widespread clinical and economic benefits. This work aims at providing an updated description of the incidence of mild TBI (mTBI) based on data from Emergency Departments (ED) in the Ile-de-France (IDF) region (Paris area).

Methods:

We estimated the mTBI incidence, using mainly data from the OSCOUR (Organisation de la Surveillance Coordonnée des Urgences) database from 01/01/2011 to 31/12/2015. The OSCOUR Network data collection methodology is based on the registration of all patients visiting the emergency services (ED) of participating hospitals. An extrapolation of the proportion of TBI patients visiting an OSCOUR ED to all ED of the IDF allowed us to compute a mTBI Annual Incidence Rate (AIR) in IDF.

Results:

Between 2011 and 2015, 95,910 mTBI patients visited the OSCOUR ED in IDF, and the AIR was estimated at 292.4/

100,000 inhabitants (when reported to the French population scale: a total of 196,000 mTBI are supposed to happen each year).

Conclusions:

The surprisingly high incidence rate of mTBI observed in this study requires an evaluation of public health measures to prevent these injuries and reduce their consequences. New screening procedures should be implemented to point out the patients at risk for complications and PCS. Alongside the care aspect, prevention should be developed to reduce the incidence of TBIs, and prevention policies should be assessed by reiterating our evaluation.

Key messages:

- Between 2011 and 2015, 95,910 mTBI patients visited the OSCOUR Emergency Departments in Ile de France, and the annual incident rate was estimated at 292.4/100,000 inhabitants.
- The mTBI high incidence rate requires an evaluation of public health measures to prevent these injuries and reduce their consequences, but also the implementation of new screening procedures.

Characterization of alcohol consumption patterns among older adults in Ireland

Viveka Guzman

V Guzman[1,3], CT McEvoy[2], J McHugh-Power[3], RA Kenny[1,3], J Feeney[1,3]
[1]Medical Gerontology, Trinity College Dublin, Dublin, Ireland
[2]Centre for Public Health, Queen's University Belfast, Belfast, UK
[3]School of Medicine, Trinity College, Dublin, Ireland
Contact: guzman.viveka@gmail.com

Background:

Identifying the factors associated with hazardous drinking patterns and problem drinking is imperative to develop appropriate intervention strategies for alcohol harm reduction among the older population. The aim of this study was 1) To explore the patterns of alcohol consumption among older adults in the Republic of Ireland, and 2) To establish possible predictors of hazardous and problem drinking in this population.

Methods:

A cross-sectional analysis was carried out on samples of individuals aged >50 years at Wave 3 of The Irish Longitudinal Study on Ageing (N = 4948). Hazardous alcohol consumption was defined as drinking above Irish guidelines [women >11 Standard Irish Drinks (SD)/week; men >17 SD/week], and/or having at least one heavy drinking episode per week (>6 SD/day). Problem drinking was defined as a score of > 2 on the CAGE instrument. Regression analyses investigated outcome differences according to socio-demographic and health characteristics. Sampling weights were applied to account for differential non-response.

Results:

The prevalence of drinking patterns was 13% for lifetime alcohol abstainers, 8% for former drinkers, 26% for occasional drinkers and 53% for weekly drinkers. Among weekly drinkers 25% exceeded the guideline threshold, 23% had at least one heavy drinking episode per week and 16% had an alcohol problem according to the CAGE. In fully adjusted models, hazardous drinking and problem drinking were associated with younger older adults, male sex, current or past smoking, higher levels of stress and/or social isolation.

Conclusions:

Our findings serve as a starting point to monitor trends of alcohol consumption among older adults in the Republic of Ireland. Our results highlight areas of opportunity for targeted screening and public interventions that seek to reduce alcohol harm among this population.

Key messages:

- In the Irish context, older adults who are younger, male, current or past smokers, with higher levels of stress and/or social isolation are more likely to engage in hazardous alcohol consumption.
- Our characterization of drinking patterns highlights areas of opportunity for targeted screening and public interventions that seek to reduce alcohol harm among older adults in Ireland.

Diabetes surveillance in Germany – strategy for the dissemination of results

Lukas Reitzle

L Reitzle[1], R Paprott[1], C Schmidt[1], C Heidemann[1], J Baumert[1], Y Du[1], C Scheidt-Nave[1], T Ziese[1]
[1]Department of Epidemiology and Health Monitoring, Robert Koch Intsitute, Berlin, Germany
Contact: reitzlel@rki.de

Background:

Diabetes mellitus is a non-communicable disease with high public health relevance in Germany. Therefore, the Robert Koch Institute startetd to establish a national diabetes surveillance system in Germany in 2016. Essential part of a surveillance system is the dissemination of health information to the relevant stakeholders to facilitate its translation into action.

Methods:

For the development of the dissemination strategy, different sources of information were used. First, an online-survey combined with structured web-research explored dissemination approaches in the international context. Secondly, a workshop with public health experts from seven countries highlighted best practice examples. Based on this information, a dissemination strategy was developed in close alignment with the scientific advisory board of the diabetes surveillance including experts from politics, prevention research, regional health reporting, physicians/diabetologists and public health scientists.

Results:

Three main questions were identified to be considered in the dissemination of health information: Which audience group is addressed? Which content is relevant to this group? What is the preferred format to communicate the information? Therefore, a diabetes report will be generated focusing on health policy makers summarizing the key information on the disease dynamic. A website containing all information including a visualization tool should facilitate access for stakeholders. Additionally, awareness needs to be raised using social media, classical media and direct interactions with relevant stakeholders.

Conclusions:

In alignment with different stakeholder groups, the diabetes surveillance developed a dissemination strategy considering international best practice examples and innovative ideas for health data visualization. The next steps are to refine the dissemination strategy based on feedback from the different stakeholder groups to ensure the use of the provided information.

Key messages:

- A dissemination strategy for the diabetes surveillance has been developed in a participatory approach including experts from various stakeholder groups.
- Next steps include the refinement of the dissemination strategy and its formats based on stakeholders feedback requirements.

Waterpipe Use Prevalence Rate in Turkey: A Meta-analysis Study

Hatice Aygar

S Aydoğan[1], H Aygar[1], MF Önsüz[1], S Metintas[1]
[1]Department of Public Health, Eskisehir Osmangazi University Medicine Faculty, Eskisehir, Turkey
Contact: haticeaygar1990@gmail.com

Background:

The aim of the study was to perform a meta-analysis of studies about the waterpipe use prevalence in Turkey.

Methods:

PubMed, Web of Science, Turkey Citation Index, TR Index and the Cochrane Library databases were screened both in Turkish and English languages to identify relevant studies by using keywords 'waterpipe use', 'prevalence' and 'Turkey'. Inclusion criteria; original and cross-sectional design, studies that done during and after the year 2010, studies that given the number of participants and number of people using waterpipe and studies that done in Turkey. Open Meta Analyst demo program was used to calculate the prevalence rate of the study groups. Since the articles were $p < 0.001$ in the heterogeneity test, prevalence rate and 95% confidence intervals were calculated from the number of cases using the random effects model in group analysis.

Results:

As a result of first literature review 26 articles were reached. Duplications were eliminated and summaries of the remaining articles were read as double-blind. Ten studies were included in the study that were suitable for inclusion criteria and quality evaluation. Seven of the studies were conducted only in university students, while 3 were community-based. As a result of the analysis, 2399 of 8845 university students used waterpipe (31.0%; 95% CI: 27.3-34.7), while 356 of the 33,129 individuals used waterpipe (1.2%; 95% CI: 0.04-2.0) in community-based studies.

Conclusions:

As a result of the comprehensive literature research, it was found that the studies on waterpipe use were less in literature and prevalence was higher than expected in university students.

Key messages:

- In university students, the use of waterpipe was more common than the community, and intervention studies about the use of waterpipe were needed.
- Waterpipe use and surveillance studies in the communities are important for taking preventive measures and monitoring health outcomes.

Description of low back pain attendances in French ED

Cécile Forgeot

C Forgeot[1], G Viudes[2], G Noel[2], A Fouillet[1], C Caserio-Schönemann[1]
[1]DATA, Santé Publique France, Saint Maurice, France
[2]FEDORU, Federation of Observatories for Emergency Medecine, Toulouse, France
Contact: cecile.forgeot@santepubliquefrance.fr

Background:

Low back pain (LBP) is one of the leading contributors to disease burden worldwide [1]. In 2018, French health care insurance launched a population awareness campaign in order to promote effective behaviour change in France. Because LBP acute episodes often lead to emergency visits, Santé publique France, the French Public Health Agency and the Federation of Observatories for Emergency Medecine, performed a pre-campaign situational analysis of LBP in the French emergency department (ED) involved in the OSCOUR® network.

Methods:

The OSCOUR network is part of the French syndromic surveillance system SurSaUD® [2] coordinated by Santé publique France since 2004. In 2017, the system collects daily individual data from about 700 ED representing 92% of the French ED attendances. Those data contain demographic, administrative and medical information including discharge diagnosis coded according ICD-10. ED attendances with a diagnosis related to LBP were analyzed from 2014 to 2017. Temporal distribution of LBP attendances, hospitalizations after discharge and stay duration in ED services were also analyzed.

Results:

From 2014 to 2017, 504 ED were included in the analysis and LBP represented 1.12% (N = 481,291) of ED all visits. This proportion remained stable over the period. 60% of LBP attendances concerned 18 to 50 years old adults and almost 10% were hospitalized after discharge. This proportion increased with age to reach 43% for the 85 years old and more. LBP attendances were more frequent on Monday. Median stay duration were almost 3 hours but increased with age and for hospitalized patients.

Conclusions:

The broad coverage of the ED OSCOUR® network on the whole territory and the strong partnership between epidemiologists and clinicians enable Santé publique France to produce reliable results which are also consistent with ED physician's perception. Finally those results can be used as a reference contributing to evaluate potential benefits of this campaign.

Key messages:

- This description of low back pain ED attendances is consistent with emergency physicians perception on field and can be used as a reference to evaluate potential benefits of the prevention campaign.
- The national coverage of the ED OSCOUR® network and the strong partnership with emergency physicians enable Santé publique France to produce relevant description on the main causes of ED attendances.

Geographic disparities in bladder cancer incidence among women in the department of Bouches-du-Rhône

Laurence Pascal

K Mantey[1], S Cortaredona[2], T Martin[3], L Daniel[4], C Clément[5], G Karsenty[3], L Pascal[6]
[1]Observatoire Régional d'Epidémiologie, ARS PACA, Marseille, France

[4]Pathology Laboratory, Public Hospitals of Marseille, Marseille, France
[5]Urology Unit, Rhône-Durance clinic, Marseille, France
[6]Regional Office Provence-Alpes-Côte d'Azur and Corsica, Sante Publique France, Marseille, France
Contact: laurence.pascal@santepubliquefrance.fr

While the incidence of bladder cancer begins to decline in men it increases in women related to tobacco smoking. The study aimed to describe bladder cancer among women in the department of Bouches-du-Rhône and assess their spatial distribution in order to detect potential spatial clusters. Cancer incidence data were obtained from the departmental observatory of cancers REVELA13. The characteristics of the cases registered were compared to those describe at the national level. Age-standardized incidence ratios (SIRs) were calculated for each commune and bayesian smoothed risk estimate based on the Besag, York and Mollie model were computed for incidence mapping. The spatial scan statistic (SaTScan) was used to investigate local cluster. Spatial analyses were adjusted on various confounding factors as a French deprivation index, access to health-care services and population density.

During the period 2013-2016, 395 cases of bladder cancers were diagnosed in women. Departmental incidence was significantly higher (3.3 cases per 100.000 inhabitants) than the national incidence (2.3). Compared to men, bladder cancers among women were diagnosed at a more advanced stage of the disease ($p < 0.01$). SIRs geographical variations were related to access of care but none of the communes showed any significant excess of cases. However, one significant cluster including nine districts of the biggest city (Marseille) and one neighbouring commune (RR = 1.76) was detected in the south east of the department.

Spatial studies of bladder cancer in women rarely find over-incidence or clusters due to lack of power. However, this study has shown that geographical disparities exist in particular because of a lesser access to a specialist. Regarding the high prevalence of smoking among women in the south of France, practitioners need to think about bladder cancer in women with urinary signs.

Key messages:

- We identify for the first time a cluster of bladder cancers in women in France.
- Practitioners need to think about bladder cancers in women with urinary signs because this cancer will become a public health issue in the future.

Challenges in a population-based registry of cardiovascular disease in Shiga, Japan

Takako Fujii

T Fujii[1,2], H Arima[2,3], T Yamamoto[4], Y Sawayama[4], N Takashima[5], Y Kita[6], S Tanaka[7], N Miyamatsu[8], K Miura[9,3], K Nozaki[1,3]

[3]Center for Epidemiologic Research in Asia, Shiga University of Medical Science, Otsu, Japan
[4]Department of Cardiovascular Medicine, Shiga University of Medical Science, Otsu, Japan
[5]Department of Public Health, Kinki University, Osaka-Sayama, Japan
[6]Tsuruga University, Tsuruga, Japan
[7]Department of Medical Statistics, Shiga University of Medical Science, Otsu, Japan
[8]Department of Clinical Nursing, Shiga University of Medical Science, Otsu, Japan
[9]Department of Public Health, Shiga University of Medical Science, Otsu, Japan
Contact: tfujii@belle.shiga-med.ac.jp

Background:

Stroke and cardiovascular disease are one of the leading causes of death and disability in Japan. In order to investigate current burden, we conduct a population-based registry of cardiovascular disease in Shiga Prefecture, Japan since 2012. We will demonstrate challenges in conduct of the registry study.

Methods:

In 2012, we established the Shiga Stroke Registry (SSR), a multicenter population-based registry study designed to build a complete information system for the management of stroke in Shiga Prefecture, Japan. The registry uses local monitoring, combined with remote data collection and quality control systems, to create an integrated surveillance system among a network of all acute care hospitals with neurology/neurosurgery facilities and smaller hospitals with rehabilitation facilities in the region. In 2019, study name has changed to Shiga Stroke and Heart Attack Registry (SSHR) and additional registration of coronary heart disease and aortic disease have started. Each case is reviewed and adjudicated by 2 or more specialists.

Results:

In the financial year of 2018 (from April to March), a total of 4809 stroke cases were identified. From December 2018 to April 2019, a total of 515 coronary heart and aortic diseases were identified. A total 10 nurses work full-time for the registry and it takes average of 1 hour to collect information for each patient. Challenges in conduct of the cardiovascular registry involve regulatory and ethical approval, funding, associations with local hospitals, non-standardized hospital diagnosis, staff training for comprehensive data collection including pathophysiology, examination and treatment, and quality control of data collection.

Conclusions:

SSHR is a population-based registry of wide range of stroke and cardiovascular disease in Shiga Prefecture, Japan. In order to keep quality of the data, we put a lot of efforts on staff training and quality control.

Key messages:

- Population-based registry of wide range of stroke and cardiovascular disease in Shiga, Japan.
- In order to keep quality of the data, we put a lot of efforts on staff training and quality control.

Case-control study about exposure to BPA and DEHP and risk of endometriosis

Margherita Ferrante

M Fiore[1], P Zuccarello[1], M Gulisano[2], M Monteleone[2], G Bonaccorso[1], G Oliveri Conti[1], C Copat[1], M Palumbo[2], M Ferrante[1]

[1]Department ''G.F. Ingrassia'', University of Catania, Catania, Italy
[2]Department of Medical Surgical Specialties, University of Catania, Catania, Italy
Contact: marfer@unict.it

Background:

BPA and DEHP are endocrine disruptors. BPA-G and MEHP are their main metabolites. The main exposure route for human is the diet. Endometriosis is a pathology with uncertain etiopathogenesis, characterized by disturbances in sex hormones balance with a prevalence in women ranged from 1% to 7% in women aged 15-45 years.

Methods:

A case-control study should highlight a possible relationship between exposure to DEHP and BPA and endometriosis. Patients (n = 40) with a surgical diagnosis of endometriosis will compose the group of cases; healthy women (n = 40) will compose the control group. Cases and controls will be studied by means of questionnaires and by means of urinary analysis of these endocrine disruptors concentration.

Results:

BPA values ranged between 0.05-8.55 and 0.05-1.84 in cases and in controls, respectively; BPA-G values ranged between 0.05-16.1 and 0.05-7.38 in cases and in controls, respectively; total BPA values ranged between 0.05-3.26 and 0.05-3.51 in cases and in controls, respectively. DEHP values ranged between 13.63-57.78 and 16.66-61.93 in cases and in controls, respectively; MEHP values ranged between 1.74-6.16 and 4.26-14.16 in cases and in controls, respectively; total DEHP ranged between 15.27-63.93 and 21.72-72.73 in cases and in controls, respectively. A reverse correlation was found between endometriosis and phthalates, while a direct correlation was found between BPA and endometriosis.

Conclusions:

The direct correlation between BPA and endometriosis suggests the decreasing the use of plasticizer in food packaging and the importance to implement interventions and strategy to minimize exposure. The reverse correlation between endometriosis and DEHP could be explained by the small size of sample and by the monitoring of urine that are representative of a short-time exposure.

Key messages:

- Improve epidemiological studies with analysis of alternative matrices that are more representative of long-time exposure.
- Implement interventions and strategy to minimize exposure to plasticizer.

Géodes: the health indicators web portal of the French Public Health Agency

Etienne Lucas

E Lucas[1], A Guillet[1], C Bonaldi[1], C Caserio-Schönemann[1], Y Le Strat[1]

[1]DATA, Santé publique France, Saint-Maurice, France
Contact: etienne.lucas@santepubliquefrance.fr

Background:

Santé publique France, the French Public Health Agency, produce numerous health indicators (diseases or health determinants) from many different data sources (specific or unspecific surveillance systems, epidemiological and behavioural surveys, administrative databases). In order to improve visibility and accessibility of these indicators, a web portal ''Géodes'' was created.

Methods:

Géodes was built with Géoclip Air© developped by a French start-up. This ergonomic tool allows to explore the geographical dimension of health indicators through interactive maps along with graphs and tables. In addition, Géodes is designed to explore the temporal dimension of indicators produced yearly or weekly through dynamic maps or time series. All indicators are linked to an explanatory sheets. Description, sources, precisions or limits of interpretation are discribed. It is also easy to present indicators in interactive tables, exportable in different formats such as Excel spreadsheets.

Results:

Since February 1st 2019, Géodes is available online without any access restriction (https://geodes.santepubliquefrance.fr). Over 300 health indicators are provided related to infectious and chronic diseases, occupational and environmental health, behaviours, emergency departement attendances, etc. An indicator is either a number of cases, a proportion or an incidence rate. Most indicators are stratified by categories such as sex or age group. It is possible to represent two indicators on a single map, e.g. the smoking prevalence and the standardised rate of lung cancer.

Conclusions:

The days following the opening to the public, the site recorded up to 10,000 connections per day. In routine, the site knows up to 200 visits per day, up to 3,000 in case of quoting aparticular indicator in the media. These figures show that this health data observatory meet a real need.

Key messages:

- A web portal of health indicators created by Santé Publique France is now available. More than 300 health indicators are integrated in the portal.
- Indicators can be visualized through interactive maps, tables and time series and their values are easily exportable and communicable.

A claims-based algorithm to identify cancers in a French retired self-employed craftspeople cohort

Hélène Goulard

H Goulard[1,2], *J Homère*[1,2]
[1]French Public Health Agency, Saint-Maurice, France
[2]Essat-Epicene-Inserm U1219, University of Bordeaux, Bordeaux, France
Contact: Helene.Goulard@u-bordeaux.fr

Background:

In France, possible long-term effects of past occupational exposure to carcinogen in the French retired self-employed craftspeople (RSEC) was studied in the ESPrI cohort. For health surveillance, a passive epidemiologic follow-up was set up, using algorithms based on medico-administrative databases developed to identify retiree with incident cancers.

Methods:

A total of 15,030 RSEC were invited between 2005 and 2009 to fill the questionnaire about social and demographic characteristics, occupational history, frequency of activities involving potential exposure to asbestos fibers. For health surveillance, health-related French administrative databases were used. Since 2009, healthcare data from 7,544 ESPrI retirees had been annually extracted from the national health insurance cross-fund information system (Sniiram), include the French hospital discharge database system (PMSI) and the registered Long-Term Diseases database (LTD). The objective was to track incident cancers (ICD-10) and their date of diagnosis using algorithm based on 1) hospital stay with principal, related or associated diagnosis; 2) historic of the registered LTD which was available for each retiree.

Results:

Among 7 544 ESPrI retirees, matching through medical records, 256 different incident cancers from asbestos-related localizations were identified between 2011 and 2017, 243 in men and 13 in women - a total number of 105 lung cancers, 122 colorectal cancers and 29 others cancers (mesothelioma, larynx, ovarian, oesophagus, pleura cancers).

Conclusions:

A passive follow-up by using French national health administrative databases in order to evaluate the potential health effect of occupational asbestos exposure offered the advantage of reducing the risk of attrition and decreasing the total cohort cost. In 2019, a study was set up with then French cancer registries to evaluate algorithm's performance.

Key messages:

- A claims-based algorithm developed by the French public health Agency to identify incident cancers.
- Epidemiological follow-up of ESPrI cohort provides indicators on the health of retired self-employed craftspeople.

Huge mortality fluctuations in working ages in Russia after 1991: is alcohol affordability in charge?

Artyom Gil

A Gil[1]
[1]Higher School of Health Administration, I.M.Sechenov First Moscow State Medical University, Moscow, Russia
Contact: artyom5@mail.ru

Background:

Mortality rates from various causes of death significantly fluctuated inRussia after1991,with especially profound amplitude observed in working age populations.This study was aimed to investigate association between affordability of alcohol(AA),pattern of alcohol drinking(PAT),and several selected mortality indicators in which large alcohol-attributable fractions were assumed.

Methods:

Econometric estimation of AA was based on calculation of the ratio of index of real disposable income to vodka price index adjusted for consumer price index.PAT was defined as the index of proportion of strong alcohol beverages sold a year in retail.Spearman's rho andKendall's tau-b correlation coefficients were estimated to assess strengths of bivariate associations between AA,PAT and indices of all-cause mortality,of mortality from external causes(EC) and from diseases of circulatory system(CSDs)at working ages(M:16-59;F:16-54yrs)in a time-series analysis between1991 and2016.All indices were calculated with1991 taken as the reference year. All primary data were obtained from the Russian Federal StateStatistics Agency"RosStat".

Results:

All-cause mortality and mortality from CSDs in both males and females quite precisely repeated fluctuations of AA between 1991 and 2005(tau-b>0.600,p<0.050; rho>0.700,p<0.050). Same moderate to high strength associations were observed between mortality fromEC and AA for 1991-2003.The strongest moderate to high strength associations between PAT and all-cause,CSD and EC mortality were observed during the period after1995, when pattern of drinking began changing towards consumption of low alcohol content beverages, especially beer. PAT repeated fluctuations of AA between 1991 and 1999.

Conclusions:

Our findings further support alcoholic hypothesis of huge mortality fluctuations in Russia during the period after 1991, suggesting that alcohol affordability had played the key role before 2005 and pattern of drinking influenced on mortality decline after 2005.

Key messages:

- Fluctuating affordability of alcohol was one of the major determinants of alcohol consumption, and, consequently, of fluctuations of alcohol-attributable mortality in Russia between 1991 and 2005.
- The ongoing from 1995 change of pattern of alcohol consumption from spirits to low alcohol content drinking likely significantly contributing to mortality decline observed in Russia after 2005.

Hypertension and body mass index in a population of 19-year-old men in Poland

Agnieszka Hubert-Lutecka

AHL Hubert-Lutecka[1], *MBB Binkowska-Bury*[1], *ZC Chmiel*[1], *GH Hejda*[1]
[1]Faculty of Medicine, University of Rzeszow, Rzeszów, Poland
Contact: hubertagnieszka@gmail.com

Background:

Hypertension is a main yet potentially modifiable cardiovascular risk factor. It is the most widespread disease of the 21st century, especially in highly industrialized societies. It is estimated that hypertension affects about 25% of the adult population in the world and reaches a ceiling of 32% and another 30% of the adult population is characterized by pressure values classified as pre-hypertensive. The prevalence of hypertension is geographically diverse and closely depends on economic and socio-cultural conditions. The relationship between hypertension and obesity is the subject of many studies that explicitly confirm the occurrence of positive coincidence.

Methods:

The study was observational-retrospective, and included a group of 17 282 men, aged 19, from the southeastern region in Poland. All subjects met the qualifications for compulsory military service in 2017. We analyzed selected data obtained from the records of the Ministry of National Defense.

Results:

Hypertension was found at 0.6%, weak body structure at 0.8% and obesity co-existing with cardiorespiratory insufficiency has been reported 2.6% of respondents. The underweight concerned almost 7%, and the overweight and obesity of 25% of conscripts. The vast majority of people with hypertension were characterized by excessive body weight (74.8%), mainly overweight.

Conclusions:

Hypertension was seen in a negligible percentage of males studied and was significantly associated with an increase in BMI, particularly with regards to being overweight. Excessive body weight significantly more often affected people with a higher degree obesity co-existing with cardiorespiratory insufficiency, affecting of the system and men with hypertension. Excessive body weight was seen in a considerable percentage of males studied and was significantly associated with the prevalence of hypertension and obesity co-existing with cardiorespiratory insufficiency, but not affecting of the system.

Key messages:

- The assumed observation contribute to the presentation of selected indicators of health status and their relationship with hypertension in a large population of 19-year-old men.
- Data obtained this way, enrich the state of knowledge about the growing problem of hypertension and they can be a valuable ground for developing educational and preventive programs for Public Health.

Open Comparisons in Public Health Not Only a Report But Also a Practical Tool Package

Elisabeth Skoog Garas

E Skoog Garas[1], *M Makenzius*[2], *H Lundborg*[3], *M Forslund*[1], *N Lindqvist*[2]
[1]Health and Social Care Division, Swedish Association of Local Authorities and Regions, Stockholm, Sweden
[2]Department of Public Health Analysis and Data Management, Public Health Agency of Sweden, Karolinska institutet, Solna, Sweden
[3]Finance and Governance Division, Swedish Association of Local Authorities and Regions, Stockholm, Sweden
Contact: elisabeth.skoog.garas@skl.se

Sweden is a high-income country with about 10 million people 2018. The public health policy has a clear focus on equitable health throughout the population, and a goal to reduce avoidable health inequalities within a generation. The 21 regions and 290 municipalities in Sweden are political self-government and important as most of the welfare services that impact citizens' lifelong health fall under their remit, for example; healthcare, childcare, education, social service, elderly care and support to people with disabilities, some emergency services, environmental issues urban planning. Therefore, the municipalities and regions need reliable data that can be compared.

Such data is available in the report Open Comparisons in Public Health (OCPH). The OPCH 2019 demonstrate large inequities in determinants of health and in health outcomes between municipalities in Sweden. Further work is needed to reduce these unjust and avoidable differences. The OPCH 2019 is not only a report, but rather a concept with additional practical tools to be used by local and regional public health officers, leaders and politicians. Following tools, developed in collaboration with stakeholders, are available in the concept OPCH.

OPCH 2019: various managementresearch review, result comparisons, suggested improvement areas

Factsheet: for leaders and politicians at policy level

Municipality reports: tailored for public health officers to save time

Socioeconomic compass: a tool to analyze differences in socioeconomics across municipalities

Kolada: the Swedish database for municipal benchmarking

Toolbox: tools to facilitate systematic interpretation and analysis

The National Public Health Agency: various statistics are available for additional analyses

Key messages:

- The OPCH and the tools contributes to initiate local/ regional development, improvement, monitoring and analysis concerning the quality and efficiency of the services delivered by these organisations.
- Governmental policies are important structural links16, but according to the OCPH 2019 the reduction of health disparities also requires measures in each local community.

Modeling the impact of changes in tobacco use on individual disease risks

Smilja Djurdjevic

S Djurdjevic[1], *G Baker*[1]
[1]Research & Development, Philip Morris International, Lausanne, Switzerland
Contact: Smilja.Djurdjevic@pmi.com

Philip Morris International has developed a Population Health Impact Model (PHIM) to estimate the effects of marketing Reduced-Risk Products on population health. The PHIM creates a disease-specific risk profile for each individual based on their age and smoking history.

To create a risk profile, the PHIM calculates, at each year of age, the excess relative risk (ERR = relative risk [RR]-1) by multiplying an individual's equivalent dose (ED) by the ERR for smoking vs. never smoking. ED is defined as 0 at birth and stays at 0 while the individual is a non-smoker. Once tobacco use starts, the individual's ED rises toward the relative exposure (RE) corresponding to the product used. Following quitting or change of product, ED moves toward the new value of RE. The model uses estimates of age- and disease-specific current smoking RRs and ERR half-lives following cessation, derived from meta-analyses of published data.

Estimates of the half-life of excess risk are also used when estimating rise in ERR following initiation or change in ERR following a change in product use. We apply the method to data for the four main smoking-related diseases; lung cancer, ischemic heart disease, stroke, and chronic obstructive pulmonary disease.

For a given disease and age group, the PHIM can derive estimates of the average ERR for each individual in the population studied. Given an overall estimate of absolute population risk, the PHIM can then also be used to derive estimates of absolute risk for each individual.

Key messages:

- Health impact modeling can be used to understand the individual and population impacts of introducing reduced risk tobacco products.
- Footnote: *Reduced-Risk Products are products that present, are likely to present, or have the potential to present less risk of harm to smokers who switch to these products vs continued smoking.

Trends in tuberculosis incidence rates in the Region of Sousse (Tunisia) from 1992 to 2016

Jihene Sahli

J Sahli[1], *M Mellouli*[1], *M Limam*[1], *M El Ghardallou*[1], *A Mtiraoui*[1], *C Zedini*[1], *T Ajmi*[1]
[1]Department of Familial and Community Medicine, University of Sousse, Faculty of Medicine of Sousse, Research Laboratory ''LR12ES03'', Sousse, Tunisia
Contact: dr-jihene19@hotmail.com

Introduction:

In 1993, the World Health Organization declared that tuberculosis is a public health emergency of global concern. All efforts were made in accordance with the Millennium Development Goals (MDGs) to reduce the burden of Tuberculosis. The MDG framework built into national priorities and development strategies has, in fact, strengthened epidemiological surveillance and the use of reliable data to make decisions based on objective data. These data are essential for planning, managing the activities of the National Tuberculosis program, monitoring and ongoing evaluation of its performance. In this context, we conducted this study to trace the trend of Tuberculosis incidence rate recorded in the Sousse Region between 1992 and 2016.

Methods:

This is a longitudinal study of the registered data of tuberculosis cases in Sousse between 1992 and 2016. For the trend analysis the software JOINPOINT version 4.5.0.1 was used. This software offers the closest possible regression model of the different points and gives an annual percentage change (APC) with a 95% confidence interval.

Results:

The highest TB incidence rates was recorded in 1993 (85.66 cases per 100 000 inhabitants). Between 1992 and 1997, there was a significant downward trend of TB incidence (APC = -23.2; 95% CI [-28.8, 1]). Between 1997 and 2004 the trend was stable. Between 2004 and 2016, there was a significant upward trend (APC = 8.3; 95% CI: [4.3, 12.4]).

Conclusions:

At the national level, between 1992 and 2002, tuberculosis experienced a fall in incidence rates, as a result of an improvement in the socio-economic level and the organization of tuberculosis control. Since 2004, the trend has been rising. Increased tuberculosis control is advocated to end tuberculosis by 2030 in line with sustainable development goals.

Key messages:

- After a significant decrease, the tuberculosis incidence has increased significantly since 2004.
- The tuberculosis prevention efforts should be intensified to reverse the current trend.

Cancer incidence trend in northern tunisia: 1994-2009

Amal Cherif

S Dhaouadi[1], *A Cherif*[1], *M Osman*[1], *M Hsairi*[1]
[1]Epidemiology/Biostatistics, Institut Salah Azaiez-Tunis, Tunis, Tunisia
Contact: amalcherif206@gmail.com

Background:

Cancer is a major public health problem in Tunisia. The objectives of this study were to describe the epidemiological pattern of cancer for all and main cancer sites in Northern Tunisia during the period 2007-2009 and to analyze it's incidence trend between 1994 and 2009.

Methods:

Cancer registry of Northern Tunisia was the source of data for the identification of patients for this study. This registry notify, since 1994, all cases of malignant tumor in people living in the District of Tunis, Nabeul, Zaghouan, Bizerte (North East) Beja, Jendouba, Kef and Siliana (North West). Cases were codified using the third version of International Classification of Diseases for Oncology. Demographic data were provided by the National Statistical Institute. Incidence trend analysis was achieved by using JoinPoint Software.

Results:

During the period 2007-2009, the age-standardised incidence rate of all sites combined was 149.2/100 000 person-years and 112.3/100 000 person-years respectively among males and females. The sex ratio was 1.26. The mean age at diagnosis was 58.28±16.77 years. The most common sites for males were: lung, bladder, prostate and colorectal; while for females, they were breast, colorectal, thyroid and cervix uteri. Local stage at diagnosis was observed in 37.7% of cases. The highest incidence rates were observed in the District of Tunis and in the governorates of North East. The trend incidence cancer of all sites combined during the period from 1994 to 2009 was significantly risen except for stomach cancer among males and cervix uteri among females with annual percent changes of -2.5% and of -4.1% respectively.

Conclusions:

Despite the existence of a national cancer strategy in Tunisia, many barriers affect the implementation of interventions; while the trend cancer incidence continues to rise particularly in males. Strengthening prevention strategy of this scourge is strongly recommended.

Key messages:

- Cancer is a major public health in world and in Tunisia.
- Prevention must be applied to reduce the incidence of cancer.

DT Injury prevention / genomics / ethics

Study of the factors associated with the delay of health consultation of victims of rape in Senegal

Mamadou Makhtar Leye

MMM Leye[1], *M Diongue*[1], *A Tal Dia*[1]
[1]Medecine, Médecine Préventive/Santé publique, Dakar, Senegal
Contact: mamadou.leye@yahoo.fr

Introduction:

Rape remains one of the most serious forms of sexual violence because of its negative impact on the physical and mental health of victims. The objective of this study is to identify the factors associated with the delay of consultation of victims of rape at the level of health structures at the level of health facilities in Senegal.

Methodology:

A retrospective, descriptive and analytical observation study was conducted. The study population consisted of all the court files of girls or women victims of rape recorded during the period from 2006 to 2015. An exhaustive recruitment of all the files of the girls or women victims of rapes answering the criteria of inclusion has been made. The uni and multivariate analyzes were carried out respectively using the software Epi Info 2000 and R 2.2.9.

Results:

At the end of the collection, 1,037 cases of rape were enlisted at the national level. The average consultation time at the health facility level was 14.6 days ± (37.9). The delay in consultation (> 24 hours) was noted in 38.6% of victims of rape. Victims of rape residing in the southern axes (ORaj = 4,31 [1,15-16,14]), north (ORaj = 4,22 [1,26-14,14]), major (ORaj = 1, 67 [1.04-2.68]), married (ORaj = 3.44 [1.58-7.5]) with pregnancy after the aggression (ORaj = 34.03 [15.47-74.85]) or an abortion (ORaj = 5.45 [1.04-24.47]) were more at risk of delaying consultation after rape.

Conclusions:

The delay of consultation makes difficult the medical and judicial care of the victim of rape. Thus, it is important for health and judicial authorities to raise awareness about the harmful consequences of sexual violence and the therapeutic benefits and the reparation of the harm suffered by the victim in case of rape.

Key messages:

- Rape. Violence.

Preventing accidents in the offshore Oil and Gas industry: An interrupted time series analysis

Demetris Lamnisos

D Lamnisos[1], M Michail[1], D Stasinopoulos[1], K Giannakou[1]
[1]Department of Health Sciences, European University Cyprus, Nicosia, Cyprus
Contact: D.Lamnisos@euc.ac.cy

Background:

Oil and Gas industry suffers from high accident rates because of the dangerous working conditions. Eastern Mediterranean countries have an immature Oil and Gas industry and therefore it is crucial for preventing accidents in this early stage to implement internationally proven successful policies. The aim of this study was to investigate whether the accident prevention policies implemented by Norwegian government in 2001 were effective in reducing accident rates in the offshore Oil and Gas industry.

Methods:

Data on the number of accidents, dates and type of facility (fixed or movable) for the years 1999-2006 were obtained from the Norwegian Petroleum Safety Authority (PSA). The effectiveness of the policy to reduce accident rates was estimated in interrupted time series analysis with post-intervention period the 1st of January 2001. Poisson regression was used to model the number of accident per months.

Results:

The dataset had 96 months with a median number of accidents per month 6.5 (IQR: 4-10) for fixed facilities and 5.0 (IQR: 3-9) for movable facilities. The analysis suggested that there was a reduction in accident rates for fixed and movable facilities. Following the policy, there was a reduction in accidents of 45% for fixed facilities (rate ratio (RR) 0.55; 95% confidence interval (CI) 0.47-0.64), while for movable facilities there was a decrease of 67% (RR 0.33; 95% CI 0.28-0.39).

Conclusions:

The policies implemented by Norwegian government in 2001 were effective in reducing the accident rates for fixed and movable facilities. The immature Oil and Gas industry of the Eastern Mediterranean countries will be benefited from studying and adopting some of the policies implemented by Norwegian government.

Key messages:

- Norwegian policies for accident prevention in the offshore Oil and Gas industry were successful.
- Oil and Gas industry of Eastern Mediterranean countries should adopt proven successful policies to prevent accidents.

Benzodiazepine use and occupational injuries: a systematic review and meta-analysis

Matteo Riccò

M Riccò[1], NL Bragazzi[2,3], AG Mezzoiuso[4], F Balzarini[4], S Garbarino[3]
[1]Dipartimento di Sanità Pubblica, Azienda USL di Reggio Emilia, Reggio Emilia, Italy
[2]Department of Health Sciences (DISSAL), University of Genoa, Genoa, Italy
[3]Department of Neuroscience, Rehabilitation, Ophthalmology, University of Genoa, Genoa, Italy
[4]Scuola di Specializzazione in Igiene e Sanità Pubblica, Università, Milan, Italy
Contact: mricco2000@gmail.com

Objective:

To investigate whether use of benzodiazepine is associated with increased risk of occupational injuries.

Methods:

PubMed, Cochrane, Embase and CINAHL databases were searched. A meta-analysis was performed to calculate odds ratio (OR) and 95% confidence interval (CI) among case controls, cross-sectional studies, either questionnaire or laboratory exams based.

Results:

A total of 20 studies met inclusion criteria, 75% of them of low quality, involving 328,805 occupational injuries from 9 different countries, with an estimated prevalence of benzodiazepine positivity of 5.3% (95%CI 4.2-6.3), significantly greater in mining industries (15.7%, 95%CI 10.8-42.2), agriculture (11.1%, 2.3-19.8), and lower in commercial drivers (0.9%, 95%CI 0.1-2.4). Among the retrieved studies, 9 were based on laboratory analyses, 7 were questionnaire-based retrospective analyses, 5 were analyses of institutional databases. In 7 cases (all questionnaire bases), rather then benzodiazepine use, a proxy was reported (e.g. sedative, anxiolytics, etc). While no increased risk for occupational injuries was found among cross-sectional studies based on laboratory specimens (OR 0.59 95%CI 0.25-1.38; I2 63%), in questionnaire-based case control studies reporting the regular uptake of benzodiazepine was associated with higher risk for occupational injury (OR 2.11 95%CI 1.30-3.43, I2 55%).

Conclusions:

These results suggest an elevated risk of occupational injuries among individuals who have reported chronic use of benzodiazepines, while no actually increased use was reported from specimens associated with the occupational injury. Even though benzodiazepines have the potential to increase injury rates among chronic users, it is reasonable to understand the underline disorders (e.g. sleep deprivation, anxiety, etc) rather than benzodiazepine use per se as the actual risk factors to be specifically addressed.

Key messages:

- Benzodiazepine use has the potential to increase the risk for occupational injuries, however evidence is conflicting.
- Underlying disorders causing the uptake of benzodiazepines rather than the drugs 'per se' are apparently associated with increased risk for occupational injuries.

Research for road safety by multidisciplinary approach in Benin: From 'ReMPARt' Unit experience

Yolaine Glele Ahanhanzo

Y Glele Ahanhanzo[1], A Kpozehouen[1], E Sambieni[2], B Hounkpe Dos Santos[1], D Daddah[1], A Aïna[2], M Poncelet[3], EM Ouendo[1], A Levêque[4]
[1]Epidemiology and Biostatistics Department, Regional Institute of Public Health, Ouidah, Benin
[2]Faculty of Litterature, Arts and Human Sciences, University of Parakou, Parakou, Benin
[3]Faculty of Social Sciences, University of Liege, Liege, Belgium
[4]Epidemiology, Biostatistics and Clinical Research, School of Public Health, Universite Libre de Bruxelles, Brussels, Belgium
Contact: nyglele@yahoo.fr

Issue/Problem:

Road crashes are the primary cause of death within the 15-29-year-old age group. In Benin, there is no policy of road safety. The establishment of effective policies requires objective data that can guide decision-making. Research institutions are poorly integrated in this process. To fill the gap in scientific evidence and to participate in the decision-making, the Department of Epidemiology and Bio-Statistics of Regional Institute of Public Health, along with partners, set up a unit research dedicated to road safety, the UR ReMPARt.

Description of the method:

UR ReMPARt, based on multidisciplinarity and intersectoriality, is the first initiative of its kind in the African sub-region. Its mission is to contribute to political decision-making on the subject of road safety via research development and on a template of sustainability of interventions. The intervention strategies are: training, research development, and knowledge transfer.

Results:

Created in May 2017, this research unit is organized around academic and professional competences from different countries. Assessment after two years shows four continuous training sessions on different themes, the development of doctoral research projects, and activities of expertise. Three Ph.D. thesis and five masters students in epidemiology are also in training to reinforce the unit. The partnership contains dedicated consortiums for the mobilization of resources in favour of the research and training for road safety.

Lessons:

Intersectoriality and multidisciplinarity are requisite to guide the relevance of the research and provide the adequate answers on the matter of road safety. The research and the targeted transfer of results remain key foundations to direct decision-making. The reproducibility of this initiative must take in consideration those principles and constitute an opportunity of sharing of experience and networking in favour of the joint cause that is road safety.

Key messages:

- Research in road safety cannot be one way vision.
- Building political decisions around conclusive data is henceforth an obligation to integrate in our practices.

The role of preimplantational diagnostics in comtemporary reproductive medicine - a survey

Desislava Bakova

M Semerdjieva[1], *A Angelchovska*[2], *D Bakova*[1]
[1]Department of Health Care Management, Faculty of Public Health, Medical University-Plovdiv, Plovdiv, Bulgaria
[2]Student, Faculty of Public Health, Medical University-Plovdiv, Plovdiv, Bulgaria
Contact: desislavabakova@abv.bg

Background:

Preimplantational diagnostics is a relatively new technique for diagnosing genetic and other abnormalities in different stages of fetal development. It provokes serious research interest and objections due to its probable consequences - the possibilities for selective abortion based on a selective approach to people depending on their hereditary peculiarities. In this connection, we conducted the present survey on society's attitude towards some aspects of preimplantation diagnostics.

Methods:

114 subjects (21 men and 93 women), aged between 18 and 60 years (mean 28.44±1.16), participated in an anonymous survey.

Results:

69.3% of respondents expressed their strong support for the application of preimplantational diagnostics. We report a dependance of approval on respondents' educational degree – participants with a secondary education approve in the smallest degree of preimplantational diagnostics $p = 0.004$ ($\chi2 = 15.40$). When comparing the results by respondents' age, it is worth noting that those older than 41 years approve in a greater degree of preimplantational diagnostics $p = 0.001$ ($\chi2 = 28.03$) – most commonly these are people with a Master's degree. It is more common for men to think that preimplantational diagnostics should be used for determining physical traits (colour of the eyes, hair etc.) and sex $p = 0.05$ ($\chi2 = 5.73$). As an explanation to their positive answer some respondents give the existence of sex-related genetic diseases. Therefore, even when the smallest doubt is present the so-called sexing should be conducted.

Conclusions:

The participants in the survey approve of the use of preimplantational diagnostics in strictly observed rules and conditions. With the present laws in force there are numerous unresolved aspects and issues. More than half of the participants (66.7%) think that contemporary reproductive technology (incl. preimplantational diagnostics) could influence positively the attempt to overcome the demographic crisis in Bulgaria.

Key messages:

- Preimplantational diagnostics is a relatively new technique for diagnosing genetic and other abnormalities in different stages of fetal development.
- We conducted the present survey on society's attitude towards some aspects of preimplantation diagnostics.

The role of civil society in child safety in Europe

Beatrice Scholtes

B Scholtes[1], *P Schröder-Bäck*[2], *H Brand*[2]
[1]Department of General Medicine, University of Liege, Liege, Belgium
[2]Department of International Health, Care and Public Health Research Institute, University of Maastricht, Maastricht, Netherlands
Contact: Beatrice.Scholtes@uliege.be

Introduction:

The complexity of injury and the multi-sectoral nature of its prevention demands a whole-of-society approach. Engaging with civil society in a form of collaborative governance is central to this approach. Civil society, defined as neither state, nor market, nor family, includes organisations such as advocacy groups, charities, professional associations etc. This study looks at the role of civil society organisations in the implementation of child injury prevention interventions in Europe.

Methods:

The method was built upon an existing approach, known as 'organigraphs'. Mintzberg and van der Heyden developed the approach to depict how organisations actually work. We further developed its practical application to explore how interventions in child safety are developed, implemented and monitored across the local, regional, national and EU levels. Professionals working in child safety in 25 European countries were asked to draw organigraphs for an intervention in one of four child injury domains: road, water, home safety or intentional injury prevention. The analysis focused on the action surrounding civil society actors, represented by the connectors leading to and from those actors.

Results:

We received 44 organigraphs in total from 31 participants in 24 countries; nine for intentional injury prevention, nine for water safety, 12 for road safety and 14 for home safety. Civil society actors were present in the majority of Organigraphs and they played multiple and diverse roles including: 'advising', 'funding' and 'implementing' child safety initiatives.

Conclusions:

The role of civil society, described in this data set, appears to be relatively well-developed. Strong, functional and long-standing partnerships between civil society actors across policy sectors and government may lead to greater capacity to address the complexity of child injury.

Key messages:

- Effective child injury prevention requires multi-sectoral action to address its complexity. Stakeholders come from the public and private sector and from civil society.
- Greater engagement with civil society may represent an opportunity for countries and regions to improve their response to the challenges of injury prevention among children.

Injury profile and healthcare expenditure of cyclists admitted in intensive care units

Maria Papadakaki

M Papadakaki[1], *Ch Gnardellis*[2], *A Tsalkanis*[3], *MA Stamouli*[4], *E Petelos*[5,6], *A Morandi*[7], *D Otte*[8], *M Sarris*[4], *G Tzamalouka*[1], *J Chliaoutakis*[1]

[4]Department of Health Care Units and Business Administration, University of West Attica, Athens, Greece
[5]Clinic of Social and Family Medicine, School of Medicine, University of Crete, Heraklion, Greece

[6]Department of Health Services Research, CAPHRI Institute, Maastricht University, Maastricht, Netherlands
[7]Centre of Study and Research on Road Safety, Medical School, University of Pavia, Pavia, Italy
[8]Hannover Medical University, Hannover, Germany
Contact: mpapadakaki@yahoo.gr

Background:

The current paper is part of the EU-funded REHABILAID Project and aims to describe the profile of cyclists sustaining severe injuries in a road traffic incident as well as the healthcare costs associated with their injury, including hospitalization costs and out-of-pocket expenditure.

Methods:

Seven public hospitals were involved; Greece = 5, Italy = 1 and Germany = 1. Both the intensive care units (ICU) and sub-intensive care units (as high-dependency areas) were involved. Participants enrolled during a 12-month period starting from April 2013 and were followed for one year from admission date. The study used widely recommended classifications for injury severity (AIS-Update 2008, MAIS). Information on the injury was retrieved upon patients' consent, from medical records while interviews were carried out at months 1,6,12 for personal and cost-related information. Health Care Expenditure was assessed through the MUARC's framework. Diagnosis-related groups (DRGs) were used to estimate hospitalization costs.

Results:

120 subjects enrolled in the study in total and 14 were cyclists(Greece = 1, Germany = 3, Italy = 10). Most of them were men(n = 9, 64.3%), with a mean age of 55.5 years (SD16.3;min 32-max 84). As for the current incidents, the majority occurred at city roads (n = 10;71.4%), straight roads (n = 9;64.3%) and intersections (n = 3;21.4%). Many were single-vehicle (n = 4;28.6%), lateral (n = 4;28.6%) and front-lateral (n = 3;21.4%). Half of the cyclists sustained an injury of MAIS3+ severity (n = 7;50.0%). A major injury was primarily sustained at the lower extremities (n = 10;71.4%), head (n = 7;50.0%), face (5 = 35.7%) and upper extremities (n = 5;35.7%). The mean total hospitalization cost was 5815,6(min 209,00-max 20.647,00) and the mean direct costs arising from injury was 4.047,5(min 0,0-max 24.670,00).

Conclusions:

Individual differences need to be taken into account in future injury prevention efforts as well as in attempts to improve healthcare system's response to road victims.

Key messages:

- Systematic collection of data relevant to health condition and economics of the victims is necessary at European level.
- Personalized rehabilitation plans are necessary to facilitate the recovery process of victims.

Early osteoporosis diagnosis improves post-hip fracture outcome

Giagkos Lavranos

G Lavranos[1], PP Manolopoulos[1], P Xenophontos[1], P Vogazianos[1], K Tsioutis[1], T Dardavessis[1], EO Johnson[1]
[1]European University Cyprus, Engkomi, Cyprus
Contact: G.Lavranos@external.euc.ac.cy

Background:

Hip fracture is associated with mortality and high rate of hospital re-admission after discharge. Osteoporosis screening and treatment have been shown to lower the risk of hip fractures. The aim of this study was to assess whether osteoporosis treatment also improves the post-hip fracture overall outcome.

Methods:

All patients over the age of 65 that sustained a hip fracture at a tertiary University Hospital were approached to enroll in the study. The patients were informed of the context of the study, all queries were answered and an informed consent was signed by the patients in the presence of one of the investigators. The data were collected over an 8 month period from October 2017 to June 2018 and the cohort was followed up until February 2019. Recorded outcomes included mortality, re-admission and unscheduled hospital visit.

Results:

The overall mortality rate of elderly patients after a hip fracture was 12.3% (n = 24) after a 6 month follow-up period. The overall event rate of elderly patients after a hip fracture was 29.7% (n = 58) after a 6 month follow-up period. Only 3% of patients were already on osteoporosis treatment. However, patients on treatment for osteoporosis had a favorable outcome with no deaths and significantly less overall events ($p < 0.0001$).

Conclusions:

Early osteoporosis screening and treatment in the elderly can not only prevent falls and fractures, but also improve outcome in case a hip fracture does occur.

Key messages:

- Osteoporosis treatment improves outcome after a hip fracture.
- Despite relevant guidance, osteoporosis screening in the elderly remains suboptimal.

DU LGBTI and minorities health

Evaluating equity in healthcare: pilot implementation of a self-assessment tool

Antonio Chiarenza

A Chiarenza[1], D Domenig[2], S Cattacin[3]
[1]AUSL Reggio Emilia, Reggio Emilia, Italy
[2]Arkadis Foundation, Olten, Switzerland
[3]University of Geneva, Geneva, Switzerland
Contact: antonio.chiarenza@ausl.re.it

Background:

Several sets of standards aiming at improving access and quality of care for service users have been published in recent years. Certain standards focused on improving healthcare providers' responsiveness to specific target groups. The general goal of this research was to improve organisations' awareness of equity standards that are not focused on specific groups, but on all contributing factors that put vulnerable groups at risk of exclusion. The specific objective was to evaluate the degree of compliance with a set of equity standards in 52 health care organisations from 16 countries.

Methods:

A self-assessment tool (SAT) was developed to allow healthcare organisations to measure their capacity to provide equitable care for service users. The SAT indicates the main areas that should be addressed: equity in policy; equitable access and utilisation; equitable quality of care; equity in participation; promoting equity. A cross-sectional survey addressing participants from pilot-organisations was used for data collection, concerning both the self-reported compliance score with the standards, as well as the additional information provided to support the score assigned. Data were analysed quantitatively as well as qualitatively.

Results:

The findings confirm that healthcare providers do invest in improving equity in the access and delivery of services to vulnerable groups. However, many health organisations have inadequate strategies to address inequities and are insufficiently engaged in improving equity in participation and promoting equity outside the organisation.

Conclusions:

The participating organisations reported a significant impact from use of the self-assessment tool: some received the support from regional/national authorities to continue working on improving equity in healthcare; others linked the equity standards to existing performance-measurement strategies; others invested in new frameworks to improve service users engagement.

Key messages:

- The implementation of the SAT contributes to a self-reflective process, involving health professionals and managers, in which gaps and potential improvements are identified.
- Pilot organisations utilised the SAT as part of a process of increasing their awareness of equity issues and changing their organisational culture.

Roma origin as a factor for high level of adolescent fertility and abortion rate in European Union

Mariela Kamburova

M Kamburova[1], S Georgieva[1], D Tsanova[1], E Stoyanova[2]
[1]Department of Public Health Sciences, Medical University, Pleven, Bulgaria
[2]Department of Midwifery, Medical University, Pleven, Bulgaria
Contact: mariela_kamburova@yahoo.com

Background:

Adolescence is a vulnerable phase in human development. Adolescent girls from Roma origin, especially younger girls, are particularly vulnerable because they face the risks of premature pregnancy and childbirth. The study aims to evaluate the association between Roma origin of mothers and prevalence of adolescent fertility and abortion rate in EU member states.

Methods:

A correlational study was conducted and data on prevalence of adolescent fertility and abortion among adolescent girls (per 1000 live births) were extracted from European database "Health for all". The means of variables in different countries were compared and Pearson's correlation coefficients with share of Roma population were calculated. Data processing was performed by SPSS v.24.

Results:

Increasing trend in premature childbirth has been observed in parallel with the increase of share of Roma population within countries, significantly more expressed in South-East member states. The mean adolescent live birth rate in the countries with highest proportion of Roma population was 5.6 times higher as compared to the mean for those with lowest proportion of Roma population. The highest level of proportion of live births to mothers aged less than 20 years was found in Romania (9.8%) and Bulgaria (9.5%). At the same tame proportion of Roma population in those countries is highest: Bulgaria (4.7%) and Romania (2.5%). The relation of adolescent fertility rate with share of Roma population shows significant positive correlation ($r = 0.804$, with 2-tailed significance $p = 0.000$). As far as the correlation of abortion among adolescent girls with the Roma origin is concerned, it is inverse and not significant.

Conclusions:

Our results indicate significant correlation between share of Roma population and adolescent live birth in EU member states. A holistic approach is needed in which socio-economic development and education of Roma girls leads to further reduction of adolescent childbirth and abortions in EU.

Key messages:

- Adolescent girls from Roma origin in EU face the risks of premature pregnancy and childbirth more expressed in South-East member states and significant positive correlation for it was found.
- Bulgaria is the country with highest share of Roma population (4.7%) and in the second place according proportion of live births to mothers aged less than 20 years (9.5%) in the EU in 2015.

A public health campaing – health promotion in Roma minority population in the City of Zagreb

Marina Polic-Vizintin

M Polic-Vizintin[1], M Škes[1], M Marić Bajs[1], Z Šostar[1], I Portolan Pajić[2], J Tucak[2]
[1]Andrija Štampar Teaching Institute of Public Health, Zagreb, Croatia
[2]City of Zagreb, City Office for Health, Zagreb, Croatia
Contact: marina.polic-vizintin@stampar.hr

Background:

Researchers into health inequalities consistently show disadvantages in health status for various ethnic minority groups. Socially and economically Roma are one of the most vulnerable and disadvantaged groups. The Roma population of Zagreb approximates 2.755 according to the 2011 census. "Health promotion in Roma minority" is public health initiative undertaken in the City of Zagreb in 2018.

Objectives:

The aim was to recognize the need for early risk factors prevention, to increase health literacy and to improve access to health-care in Roma minority.

The stakeholders involved in this program were Roma NGOs, Andrija Stampar Institute of Public Health, local Medical Centre and City office for health. The role of Roma activist was inportant for including Roma population.

Results:

In order to assess the health status and health-related lifestyle attributes a multidisciplinary approach was carried out including a total of 141 members of the Roma minority living in three different quarters. Activities included preventive exams, conducted workshops "Reproductive health", "Access right to health-care"and "Healthy lifestyles". Hypertension was found in 15,6% Roma using standard diagnostic criteria (i.e. BP $\geq$ 140/90 mm Hg). High blood shugar was found in 16,3% Roma. Screening mammography exams were also carried out including 73 Roma women over 50. BI-RADS 3 category was found in 17 women (23,3%) and BI-RADS 4 + 5 category was found in one woman.

Conclusions:

The multisectoral collaboration and the involment of Roma activist could help to achieve better inclusion of Roma population, better perception of the health messages and behavioural changes. Health sector should promote and advocate for healthier lifestyle, but community and policy are to support and complement the actions. Access to health care cannot be discussed in isolation from other problems this population group experiences, such as poverty, restricted access to education and social exclusion.

Key messages:

- The empowerment is an outcome of health literacy, but does not automatically lead to empowerment.
- Individual's social and cultural context must be in focus. The involment of Roma activist could help to achieve better results.

Roma populations and health inequalities: a systematic review of multiple intersecting determinants

Lois Orton

L Orton[1], RM Anderson de Cuevas[1]
[1]Department of Public Health & Policy, University of Liverpool, Liverpool, UK
Contact: l.c.orton@liverpool.ac.uk

Background:

Roma populations experience significantly poorer health than majority populations. Health outcomes are often worse than for others in similar social positions, suggesting differences are not simply the effect of poverty. Roma women are thought to be worst affected. However, data pertaining to the multiple social inequalities affecting Roma populations, their interaction and cumulative effect on health over time, have yet to be synthesised.

Methods:

We searched four bibliographic databases (MEDLINE, Science Citation Index, Social Sciences Citation Index and Scopus), screened reference lists, consulted key informants and searched organisational websites for studies providing empirical evidence on more than one determinant of health for Roma populations in Europe. Two reviewers carried out screening, data extraction, quality appraisal and performed a narrative synthesis.

Results:

From 2,043 bibliographic records, 37 studies met our inclusion criteria. The median number of influencing factors explored through qualitative and quantitative methodologies was 2 (range 1 - 5) and 3 (range 1 - 11), respectively. Quantitative studies focussed on poverty (10 studies) and other indicators of socio-economic status including education (13 studies), housing (9 studies) and employment (9 studies). Very few studies unpicked interactive effects instead testing each factor's contribution to poor health independently. Qualitative studies tended to explore "Roma culture" (11 studies) and the impact of discrimination/racism on health behaviour (10 studies). There is a lack of gender-disaggregated data and little analysis of the impact of social policy on the health of Roma populations.

Conclusions:

Evidence for associations between determinants and health outcomes among European Roma populations is patchy. Research needs to pay more attention to the health impact of social policies that have the potential to reinforce (as well as mitigate) the exclusion of Roma populations.

Key messages:

- This systematic review critically analyses the state and shape of research evidence on the multiple interacting axes of inequality that contribute to poor health among Europe's Roma populations.
- There is a divergence between qualitative and quantitative studies, with the former providing some evidence on socio-economic status and the latter exploring aspects of culture and discrimination.

Pre-exposure prophylaxis in a sexual health clinic for Men who Have Sex with Men in Portugal

Sofia Ribeiro

S Ribeiro[1,2], *M Rocha*[1]
[1]CheckpointLX, Grupo de Ativistas em Tratamentos, Lisbon, Portugal
[2]Department of International Health, CAPHRI, Faculty of Health, Medicine and Life Sciences, Maastricht University, Maastricht, Netherlands
Contact: sofiafigribeiro@gmail.com

Background:

Pre-exposure prophylaxis (PrEP) is defined as the use of antiretroviral drugs to prevent HIV acquisition in uninfected individuals. Recognizing the increasing use of informal PrEP in Portugal, CheckpointLX, a community clinic targeted for MSM in Lisbon, Portugal, began offering counselling and follow-up services prior to formal introduction. This study aims to characterize PrEP users attending CheckpointLX before formal PrEP introduction in Portugal, and those who were referred to PrEP in the National Health Service (NHS) following formal approval of PrEP.

Methods:

Data was collected by peer counsellors between May 2015 and September 2018 and inserted in a database. Medical care followed EACS recommendations for PrEP eligibility, initiation and follow up. For formal PrEP, the General-Directorate for Health's PrEP guidelines checklist was used.

Results:

Until the end of May 2018, CheckpointLX had a total of 90 appointments for Wild PrEP, of which 64 (71%) were first time visits. As for the 380 service users referred to the NHS, most were Portuguese (N = 318, 84%), and the mean age was 31 (8.9) years old. Condomless sex in the last six months with partners of unknown HIV status was the most common eligibility criteria (N = 59, 83%).

Conclusions:

PrEP delivery should be complemented with effective information on the importance of immunization and education on safer practices of drug administration, in the scope of broader preventive sexual health care. Much remains to be done in Portugal to ensure that PrEP is available to those who need it the most. Offering PrEP at community clinics could be a first step.

Key messages:

- Condomless sex in the last six months with partners of unknown HIV status was the most common eligibility criteria for PrEP.
- PrEP delivery should be complemented with effective information on the importance of immunization and education on safer practices of drug administration.

Reality of trans-identity in Benin and social reactions: Analysis based on a national survey in 2017

Yolaine Glele Ahanhanzo

S Hessou[1], *Y Glele Ahanhanzo*[2], *A Kpozehouen*[2], *T Yadouleton*[1], *O Sodoloufo*[1], *V Capo-Chichi*[3], *B Dossoh*[3], *B Gnanhoui-David*[4], *M Nelson*[4]
[1]Plan International Benin, Cotonou, Benin
[2]Epidemiology and Biostatistics Department, Regional Institute of Public Health, Ouidah, Benin
[3]Leadds Consulting, Cotonou, Benin
[4]Plan International Canada, Ottawa, Canada
Contact: nyglele@yahoo.fr

Background:

Transgender individuals are a key population recognized transmission of sexually transmitted infections (STIs) and human immunodeficiency virus (HIV), with higher risks of infection. Adoption of risky behaviours would be strategies of coping to face psychological disorders related to the social consequences of gender transition. To address their specific health needs in Benin, this study describes transgenderism and social reactions.

Methods:

Through a cross sectional design, subjects were recruited by respondent-driven sampling from networks selected in the whole of the country in 2017. Subjects included were above 15 years old who identify themselves as transgender. Data was collected via questionnaires with variables related to the individual management of gender affirmation, social reactions, and risky behaviours.

Results:

A total of 326 transgender individuals were identified with a majority of subjects being originally of the male gender (89.57%). The average age was 24.13±4.88 with a strong representation of schoolchildren and students (36.50%). In 64.72% of the cases, the family was informed of the trans-identity. The overall attitude of the family was of acceptance/support in 7 cases out of 10. Stigmatization and discrimination are reported by 50% of the subjects and 59.02% have been subjected to at least one assault. Among these, half had no appeal initiative and the main reason would be the absence/non-knowledge of legal remedy. Sexual multi-partnership which is the most common risky behaviour occurred in 81.54% of the cases.

Conclusions:

Transgender people exist and constitute a population with specific needs in Benin. The services dedicated to this target must integrate the prevention of STIs/HIV but also legal, social and psychological support.

Key messages:

- Transgenderism in Benin mainly concerns young male subjects.
- Prevention programs should also be focused on social and psychological aspects to manage the identity transition that constitute a key step of shifting into risky behaviours.

Knowledge and sexual behaviors of transgender individuals faced with the risk of STI/HIV in Benin

Yolaine Glele Ahanhanzo

S Hessou[1], *Y Glele Ahanhanzo*[2], *A Kpozehouen*[2], *A Biaou*[3], *T Yadouleton*[1], *O Sodoloufo*[1], *V Capo-Chichi*[4], *B Dossoh*[4], *B Gnanhoui-David*[5], *M Nelson*[5]

[1]Plan International Benin, Cotonou, Benin
[2]Epidemiology and Biostatistics Department, Regional Institute of Public Health, Ouidah, Benin
[3]Programme National de Lutte contre l'Ulcère de Buruli, Cotonou, Benin
[4]Leadds Consulting, Cotonou, Benin
[5]Plan International Canada, Ottawa, Canada
Contact: nyglele@yahoo.fr

Introduction:

The issue of sexually transmitted infections (STIs) and Human Immunodeficiency Virus (HIV)/Acquired Immune Deficiency Syndrome (AIDS) cannot be solved without considering the transgender population. This research aims to describe the knowledge, attitudes and sexual behaviors of transgender individuals faced with the risk of STIs and HIV/AIDS in Benin.

Methods:

Transgender individuals were selected by respondent-driven sampling throughout the country in 2017. Included in this analysis were individuals who identified as transgender and adopted its mode of expression, aged 15 years and greater, and who gave their consent to participate.

Results:

A total of 308 transgender individuals were surveyed, of which 89.6% were of male gender at birth. The participants had a good level of knowledge in the matter of STI and HIV/AIDS. In fact, 99.9% among them cited at least one symptom of STIs; 95.1% cited the three main methods of transmission of HIV and 54% are aware the risk of sexual transmission of HIV is higher between men. Participants were more than 90% likely to declare a positive attitude to care for persons living with HIV (PLWHIV) or to share the same room with them (93.2%). Concerning sexual behaviors, the average age at the first sexual encounter as a transgender individual was 14 years old. During the last three months, transgender individuals declared three regular male partners on average. The usage of condoms during the last sexual intercourse was reported in 86.6% of cases. Knowledge of the serological status of the sexual partner (31.7%) and the loss of sensation induced by the condom (26.8%) constituted the main reasons of non-usage of condoms.

Conclusions:

Although adopting some risky sexual behavior, transgender individuals are a population that is relatively well informed and with favorable attitudes regarding STIs and HIV/AIDS. These factors are significant assets to be considered in the development of programs for STIs and HIV/AIDS control.

Key messages:

- Transgender individuals good level of knowledge is an asset for STIs/HIV control.
- Sexual multi-partnership seems to be common despite a good level of knowledge.

Trough community mobilization to better health for all Balkan's Roma

Zoran Bikovski

Z Bikovski[1]

[1]KHAM, NGO, Delcevo, Macedonia
Contact: z_bikovski@yahoo.com

Issue:

The Roma community in all Balkan countries faces a lot of barriers in the implementation of their health right. They face inequalities in healthcare, prejudices, stereotypes and informal payments, charged by health professionals. They also have lack of access to information about ongoing changes in the health sector. Because of lack of education, poverty or some traditional barriers, Roma usually delay on Doctors treatment or improperly used a medical therapy. Roma community also faced and with populism activities related to them who exist just on the paper, without implementation.

Description of the problem:

Implementation of Methodology, Social accountability and Legal Empowerment'' give visible results in improving Health rights of Roma community in Macedonia. In the last three years NGOs KHAM and ESE providing mentorship to the Roma NGOs in Romania and Bulgaria. Role of the NGOs is to created power balance between Roma community and Health Authorities, and addressing problems from local to national level. Trough Legal Empowerment community learn their rights, and trough Social accountability they demand there rights and looking for changes. After three years of work we have visible results and Roma movement for health rights in Balkan region.

Results:

Good practices from Macedonia was in Bulgaria and in Romania. Roma communities from Romania have progress in field of immunization of children and prenatal and antinatal care.In Bulgaria we have progress in early child development. For the very first time, Roma community sat together with Policy makers and with the arguments negotiated for better health. Details will be presented at the Conference.

Lessons:

Mentoring is excellent tool for sharing the good practice between NGOs where similarities are obvious. In fact, by acting together, more pressure can be placed on the authorities to bring better policies for Roma in the region.

Key messages:

- Knowledge is power.
- Only legally strengthened communities that collaborate with each other can make changes for themselves.

Understanding discrimination faced by transgender people in the health and social care settings

Christina Dziewanska-Stringer

C Dziewanska-Stringer[1], *H D'Souza*[1], *E Jager*[1]

[1]Public Policy: Health, ICF, Brussels, Belgium
Contact: christina.dziewanska-stringer@icf.com

Background:

This session reports on a literature review from a study aiming to identify whether there is a positive correlation between inclusive legal gender recognition procedures, and well-being of transgender people within the EU. The review explores socio-demographic/economic profiles of transgender people, and forms of discrimination faced.

Methods:

The review is based on 47 peer-reviewed articles and 11 grey literature reports, provides analysis concerning sociodemographic/economic positions of transgender people, and an overview of discrimination faced.

Results:

The focus is discrimination within health & social care, how this leads to unmet health needs and a lower sense of wellbeing within the trans population. Due to actual, or expected, discrimination, some trans individuals will not disclose their gender identity in a healthcare context, or may avoid using such services altogether. Mental health was a focus of many of the studies, with prevalence of depression, self-injury, and suicidal thoughts being higher for this group. Fewer studies reported on the physical health status, with some studies finding that transgender people had low health status. Studies suggest that professionals may treat trans people in an insensitive or inappropriate way, largely due to a lack of knowledge/ignorance, for example health & social care staff often had little knowledge of trans people and their health & wellbeing, how to appropriately address them, and how to support their care. Trans individuals may also be treated in a discriminatory way in the context of trans-specific healthcare, for e.g within a gender unit due to a non-binary gender identity.

Conclusions:

Discrimination has a negative impact on health & wellbeing, specifically mental health, mainly due to discrimination trans people face.This has a negative effect on actual/future health & well-being, as it translates into fear of seeking care, and postponing/avoiding care, due to actual or expected poor treatment.

Key messages:

- The review contributes to an evidence base to address discrimination faced by transgender people, however there is a lack of evidence found in the area of EU transgender health and wellbeing issues.
- The study seeks to confirm a positive correlation between inclusive LGR and well-being of transgender people in the EU, which can help contribute to improving their quality of life.

The clusters and frequencies of adverse social conditions amongst the homeless people

Mzwandile Mabhala

M Mabhala[1]
[1]Department of Public Health and Wellbeing, University of Chester, Chester, UK
Contact: a.mabhala@chester.ac.uk

Background:

A growing body of evidence identifies interconnected social indicators that can lead to homelessness. Several studies identify a catalogue of social disadvantages that starts from childhood and persist throughout the life course that leads to homelessness. Qualitative evidence indicates that their adverse childhood experiences(ACEs) and damage that occurred to them as children had major influences on their ability to negotiate their way through the education system, gain and sustain employment, make appropriate choices of social networks, and form and maintain healthy relationships as adults. However, very little research seeks to objectively investigate these issues. This study aims to use the cross-sectional study to document the cluster and frequency of adverse social conditions amongst the homeless people in North West England in 2019.

Methods:

The study design was cross-sectional. We used IBM SPSS 21, with a significance level set at $p < 0.05$, CI 95% to analyse the data.

Results:

The mean age was 39.12, range 21-64, 90.5% male. 52%($\chi2 =$ 33.4, df = 1, p = 0.001) described their health as poor, 90% ($\chi2 =$ 61.85, df = 2, p = 0.001) smoked cigarette daily, 83.3% ($\chi2 =$ 76.4, df = 3, p = 0.001) used drugs daily, 78.6% ($\chi2 =$ 13.7, df = 1, p = 0.001) saw a doctor in preceding 6 months, 63.4% ($\chi2 =$ 73.8, df = 3, p = 0.001) left school before age 16; 26.2% ($\chi2 =$ 37.7, df = 3, p = 0.001) left school at 16, 11.9% ($\chi2 =$ 33.1, df = 10, p = 0.001) encounterd criminal justice system at the age of 11, 28.6% ($\chi2 =$ 60.8, df = 8, p = 0.001) had reprimand/caution or conviction at 17.

ACES: 57% ($\chi2 =$ 34.7, df = 3, p = 0.001) experienced humiliation by adults in their household; 54% ($\chi2 =$ 30.7, df = 3, p = 0.001) threatening behaviour, 50% ($\chi2 =$ 26.0, df = 3, p = 0.001) physical violence in their household.

Conclusions:

These early stage preliminary results indicate that adverse social circumstances that occur in childhood are disproportionately represented in homeless population.

Key messages:

- Homelessness is more complex than the absence of accomodation.
- Adverse social circumstances that occur in childhood are disproportionately represented in homeless population.

Are Roma people exposed to NCD? Modifiable risk factors in a rural Roma community from Romania

David Mangaloiu

D Mangaloiu[1], *E Bratu*[2], *F Furtunescu*[2], *D Minca*[2]
[1]Carol Davila University, Bucharest, Romania
[2]University of Medicine and Pharmacy ''Carol Davila'', Faculty of Medicine, Preclinical Department III - Complementary Sciences, Discipline of Public Health and Management, Bucharest, Romania
Contact: david_valentin72@yahoo.com

Background:

Knowing the prevalence of modifiable risk factors for noncommunicable diseases is the first step to plan effective public health interventions. The study aims to identify the prevalence and distribution of risk factors of non-communicable diseases (NCD) among adult Roma population in a rural community.

Methods:

Using a tool based on the WHO stepwise approach, a cross-sectional study was carried out among a sample 116 adults aged 18-85 years (52 male and 64 female), from a rural community with 800 Roma members. The study instrument included questions to record behavioral risk factors (smoking behavior, alcohol drinking, diet and physical activity and also data on anthropometry and value of blood pressure). Descriptive statistics methods were used to analyze the data.

Results:

The smoking prevalence was 35,3% (95%CI, 27.0 to 44.3,) higher for men (49,9%, 95%CI, 36,6-63,4%) than for women (23,4%, 95%CI, 14.2-34,9), higher than the smoking prevalence recorded for Romanian population in 2017 Eurobarometer study. Prevalence of obesity (body mass index $\geq$30 kg/m[2]) was observed to be high among Roma respondents 34,48% (95% CI, 26,26 to 43,47) compared with self-reported obesity rates among adults in Romania (9%, Eurostat, EHIS 2014). The observed proportion of obesity is similar for both genders, but central obesity was lower for men compared to women (57,4% to 79.6%). There was observed a higher proportion of people declaring they eat fruits less than once on a week (25%, 95% CI, 17,7 to 37,4) and adding salt before tasting the dishes (58,6%). Most of interviewed people have a sedentary lifestyle with less than 30 minutes of physical activity per day.

Conclusions:

The high prevalence of risk factors for NCD in this rural Roma community indicates the likelihood of a high future burden of illness.

Key messages:

- There is a need for both further research into the health of Roma people regarding NCD and prevention interventions to address behavioral risk factors for NCD.
- Knowing the prevalence of modifiable risk factors for noncommunicable diseases is the first step to plan effective public health interventions.

DW Public health policy

Effects of Private Health Insurance on Unmet Medical Experience in Chronic disease Patients

Hyoeun Cho

JH lee[1]
[1]Public Health Policy, Korea University, Seoul, South Korea
Contact: bram50@nate.com

Background:

Chronic patients are called 'long-term disorders,' as they last for more than a year. They need continuous care, so health care through easily accessible medical institutions such as primary care is needed for them. In South Korea, however, they are mostly managed through secondary medical service systems, such as hospitals that are difficult to access. This causes them to increase their own burden rate, limiting their ongoing management of the chronic disease. However, it is known that Korea's private health insurance policy affects the use of medical services, their own burden rate and reduces the unmet medical experience. Therefore this study aims to analyze the impact of the Korean chronic disease on private insurance subscription and unmet medical experience.

Methods:

Using the 2014 survey data of the Korea Welfare Panel, the final analysis of the study was 4,243 households with chronic diseases among 6,581 households. The independent variable of this study is whether private health insurance is subscribed or not, and the dependent variable is unmet medical experience due to economic factors. The analysis method used frequency analysis and logistic regression. [Use SPss 22 for analysis]

Results:

- 1,417(33.4%) of households subscribed to private insurance. The figure is significantly lower than the country's reported private health insurance subscription rate (72.6%).
- Based on the median income of 60 percent of household income, high-income households have lower unmet medical experience than low-income households.
- In the case of unsubscribed private health insurance among the people with chronic diseases, the unmet medical experience was 1.921 times higher than that of those who signed up.

Conclusions:

- In order to reduce the burden on chronic patients, the government needs to strengthen the primary medical care system.
- Reinforce connectivity with private insurance through public financial support of national health insurance.

Key messages:

- Chronic disease.
- Private health insurance.

Barriers by professionals in primary care in discussing children of substance abusing parents

Margreet Van Der Meer

M Van Der Meer[1,3], DEMC Jansen[2], GG Anthonio[1,2]
[1]Research and Development, Verslavingszorg Noord Nederland, Groningen, Netherlands
[2]Sociology, Rijks University Groningen, Groningen, Netherlands
[3]Lectorate Addiction, Hanze University of Applied Sciences, Groningen, Netherlands
Contact: m.vandermeer@vnn.nl

Background:

Children of substance abusing parents are more at risk to develop addiction or psychiatric problems than children of healthy parents. It is therefore important to detect in an early stage, which consequences the problems of the parents might have on the child. Previous research shows that within addiction care children of substance abusing parents are not always in the picture. However for early detection it is at least as important to discuss the influence of parental substance abuse on the children in primary care: early detection of problems in children contributes in starting prevention or treatment programs in a timely manner, so that the chance that a child grows up safely will increase.

Aim:

To gain insight in the barriers of professionals working in primary care and public health in bringing up the topic of children in a conversation with substance abusing parents.

Methods:

A qualitative design was used. 15 interviews have been conducted with participants consisting of primary care and public health professionals in the Netherlands. By discussing several themes, information on the barriers experienced by the professionals were obtained, written down and analyzed.

Results:

The results are being analyzed at this moment, but will be ready to present at the congres in November. The interviews will show which barriers are experienced by the participants. Based on literature the expectation is that the barriers can be divided in three categories: barriers on the content of care, moral dilemma's and organizational barriers.

Conclusions:

The results of this study will provide insight in the barriers of professionals in primary and public health on discussing the circumstances of children of substance abusing parents. Knowing these barriers might serve as input for interventions to remove these barriers and for recommendations to improve so that children of substance abusing parents receive (preventive) care earlier.

Key messages:

- Gain insight in barries of professionals in primary care and public health on discussing circumstances of children of substance abusing parents.
- input for interventions so that children of substance abusing parents receive care earlier.

Legal policy challenges in withdrawal of dialysis treatment in Japan

Miho Tanaka

M Tanaka[1], S Kodama[2]
[1]Japan Medical Association Research Institute, Japan Medical Association, Tokyo, Japan
[2]Graduate School of Letters, Kyoto University, Kyoto, Japan
Contact: mipomipotky@gmail.com

Issue/problem:

In 2017, Japanese dialysis patients and kidney transplant cases numbered roughly 330,000 and 1,700, respectively. In March 2019, a patient died after a physician terminated her kidney dialysis at a hospital in Tokyo. The Tokyo Metropolitan Government and the Japanese Society for Dialysis Therapy (JSDT) investigated the case, questioning the patient's terminal status and desire to withdraw her request to terminate dialysis.

Description of the problem:

No Japanese law addresses treatment withdrawal, but several court decisions and the Ministry of Health, Labor and Welfare's process guidelines and JSDT guidelines address treatment withdrawal from terminal patients. We examined relevant court decisions and guidelines, identifying three legal policy issues that may impact legal policy discussions on treatment withdrawal in other countries, regardless of the enactment status of such laws.

Results:

First, the patient was not ''terminally ill'' as defined by the court rulings and guidelines. Second, a clear decision based on appropriate informed consent from the patient seemed absent, violating the court rulings and guidelines. Third, the physician's judgment of patient competency for decision-making may have been missing.

Lessons:

We considered problems beyond the court rulings and guidelines by focusing on the patient's right to self-determination and treatment refusal in other countries. The Patient Self-Determination Act and the Patient's Bill of Rights (US) as well as court rulings and the NHS Charter (UK) guarantee such rights, and collectively enable competent patients in the US, UK, and elsewhere to refuse dialysis even if they are not terminal. Japanese legislation does not guarantee such patient rights or the explicit allowance/prohibition of treatment withdrawal, regardless of the patient's terminal status; enactment of such laws should be considered.

Key messages:

- We identified legal ambiguity due to a lack of the patient's right to both self-determination and treatment refusal.
- This could impact the international discussion on dialysis treatment withdrawal.

A discourse network analysis of the public media debate on the UK Soft Drinks Industry Levy

Shona Hilton

CH Buckton[1], G Fergie[1], P Leifeld[2,3], S Hilton[1]
[1]MRC/CSO Social and Public Health Sciences Unit, University of Glasgow, Glasgow, UK
[2]Department of Government, University of Essex, Colchester, UK
[3]School of Social and Political Sciences, University of Glasgow, Glasgow, UK
Contact: shona.hilton@glasgow.ac.uk

Background:

On 6th April 2018, the UK Government introduced the Soft Drinks Industry Levy (SDIL) as a policy designed to reduce population level sugar consumption and related illnesses. Given that the successful introduction of upstream food and nutrition policies is a highly political enterprise involving multiple interested parties, understanding the complex network of stakeholders seeking to influence such policy decisions is imperative.

Methods:

Media content analysis was employed to build a data set of relevant articles from UK national newspapers. Articles were analysed to identify stakeholder agreement or disagreement with defined concept statements. We used discourse network analysis to produce visual representations of the stakeholder network and coalitions evident in the debate, leading up to and following the announcement of the SDIL.

Results:

We identified 3,883 statements made by 214 individuals from 176 organisations, relating to 47 concepts. Visualisations revealed a complex network of stakeholders with two discourse coalitions. Polarisation arose from 3 factors: (i) differences in political ideology; (ii) position on the specific policy option; (iii) interpretation of the evidence. Industry stakeholders appeared less united before the SDIL announcement. Some industry actors appeared in the supportive coalition, possibly due to the use of corporate social responsibility rhetoric. Jamie Oliver was a dominant supportive stakeholder, suggestive of his role as a policy entrepreneur.

Conclusions:

This study illustrates the complexity of the network of stakeholders involved in the public debate on food policies such as sugar tax and the SDIL. Public health advocates seeking to gain support for future upstream regulation to promote population health would benefit from tailoring their communication to take advantage of sources of polarisation. Vocal celebrity policy entrepreneurs may be instrumental to facilitate alignment of stakeholders around a clear ideology.

Key messages:

- This study provides a novel insight into the network of stakeholders involved in public debates on food policies.
- Public health advocates may benefit by identifying and aligning with a clear ideology.

A comparison of stakeholder networks across two pricing policy debates using discourse analysis

Shona Hilton

S Hilton[1], C Buckton[1], G Fergie[1], T Henrichsen[3], P Leifeld[2,3]
[1]MRC/CSO Social and Public Health Sciences Unit, University of Glasgow, Glasgow, UK
[2]Department of Government, University of Essex, Colchester, UK
[3]School of Social and Political Sciences, University of Glasgow, Glasgow, UK
Contact: shona.hilton@glasgow.ac.uk

Background:

Public health policy development is subject to a large number of stakeholders seeking to influence government thinking on policy options. One approach is via the news media. We compare the competing discourse coalitions evident in the UK public debate across two pricing policies, Minimum Unit Pricing (MUP) for alcohol and the Soft Drinks Industry Levy (SDIL).

Methods:

Existing discourse network analyses (DNA) for MUP and SDIL were harmonised in Visone to allow direct comparison. We applied a common tie-weight threshold to reduce ties to robust argumentative similarities and to maximise the identification of both network structures. We used network measures (size, density and EI index) to compare the two networks and principal coalitions.

Results:

Both networks involve a similar range of stakeholder types and form two discourse coalitions representing proponents and opponents of the policies. The SDIL network is larger, particularly the proponents coalition with over three times as many nodes and a lower EI index. Both networks show tight discourse coalitions of manufactures and commercial analysts acting in opposition to policy supporters. The only actors that appear in both debates are politicians, government advisors, commercial analysts and supermarkets. While public health actors appear in both debates they appear siloed in their interests.

Conclusions:

DNA enabled direct comparison of the discourse coalitions across two highly contested pricing policy debates, visualising the complex network of actors and relationships operating to influence policy-making via the media. Use of comparative DNA across policy debates shows promise for better understanding the common tactics of different unhealthy commodity industries (UCIs) to disrupt public health policies. Public health actors could improve their response to UCIs by seeking to work across policy and commodity arenas.

Key messages:

- We compared the competing discourse coalitions across two pricing policy debates, MUP and SDIL.
- Public health advocates could improve their response by working across policy arenas.

Optimising message framing to advance cancer prevention pricing interventions in the UK and US

Shona Hilton

CH Buckton[1], T Ikegwuonu[1], JGL Lee[2], R Carey[3], JV Cristello[4], EM Trucco[4], S Golden[5], DI Conway[6], S Hilton[1]
[1]MRC/CSO Social and Public Health Sciences Unit, University of Glasgow, Glasgow, UK
[2]College of Health and Human Performance, East Carolina University, Greenville, USA
[3]Health Psychology Research Group, University College London, London, UK
[4]Department of Psychology, Florida International University, Miami, USA
[5]Department of Health Behaviour, UNC Gillings School of Public Health, Chapel Hill, USA
[6]School of Medicine Dentistry and Nursing, University of Glasgow, Glasgow, UK
Contact: shona.hilton@glasgow.ac.uk

Background:

One-third of the burden of cancer is associated with four health harming behaviours - tobacco use, alcohol consumption, poor diet and physical inactivity. The growing evidence base supporting price-related policies to curb over consumption is of interest to governments globally. However, implementation requires public and policy-maker support. The aim of this study is to enhance our understanding of the features of message framing that influence public support for price-related policies in relation to tobacco, alcohol, and sugar.

Methods:

We conducted 18 semi-structured interviews (9 UK and 9 USA) exploring knowledge, attitudes, and beliefs of 4 price policies in relation to tobacco, alcohol and sugar. Interviewees included cancer policy advocates, cancer survivors and members of the public. We used NVivo 12 to organise the data for inductive and deductive thematic analysis.

Results:

Common supportive features included: (i) highlighting the health benefit (eg reduced cancer risk), arising from impact on purchasing behaviour; (ii) indirectly making the health harm associated with consumption clear. Common unsupportive features included: (i) policy effectiveness will depend on size of the financial penalty and consumer response; (ii) such policies are unfair on sensible consumers and potentially regressive. Interviewees were more supportive of price-related policies for products containing tobacco where they perceived a stronger association with cancer risk.

Conclusions:

This study reveals important differences in levels of persuasiveness arising from the framing of messages to promote price-related policies. The results informed the identification of 4 frames to be tested in a multi-factorial quantitative study, currently under way. These frames can be characterised as: F1 - To reduce the financial strain on healthcare systems; F2 - For the protection of children; F3 - To reduce cancer risk; and F4 - To reduce the risk of other non-communicable diseases.

Key messages:

- Tailoring the framing of price-related policies in relation to the product they are applied to may increase public acceptability.
- This may in turn facilitate their implementation.

Feasability of a regional assessment of needs for palliative care

Michel Tahon

L Thiriet[1], *M Tahon*[1], *S Matz*[1]
[1]French National Health Insurance System, Villeneuve-d'Ascq, France
Contact: michel.tahon@assurance-maladie.fr

Objective:

The coverage of need for palliative care is in the heart of national and local concerns. This feasibility study of an assessment of needs from SNDS data was done to check if this type of data permit to obtain a diagnosis of the management of the need and how measurement accuracy SNDS data used in the valuation model may be a decision-making tool.

Study design:

In this observational descriptive and analytical retrospective cohort study, the use of palliative care was identified by a code ''palliative care'' when there was a contact while a sliding twelve-month period before death with an establishment of care in France.

Patients: Patients dead in 2014 residing in Hauts-de-France were included if causes of death were identical to a defined list of diseases.

Methods:

Factors influences on palliative care access was analysed by logistic regression. Among other analyzes, survival was studied by cox model.

Results:

In medicine obstetric surgery, 28,4% of the 37502 insured adults had palliative care. For the adults, palliative care access was multipied by a factor of 0.94 ($p = 0.02798$) when men, 0.78 ($p = 0.00483$) with AME or CMU, 0.97 ($p < 2e\text{-}16$) with age, 0.90 ($p < 2e\text{-}16$) with the increase of the deprivation index, 1,01 ($p < 2e\text{-}16$) with interventional act and instantaneous death rate was multiplied by a factor of 1,0035 ($p < 2e\text{-}16$) with the use of palliative care.

Conclusions:

The estimation model of the need has probably induced a selection bias. The lack of code in primary care, the modality to be authorized to offer palliative care and the coding advocated by the health insurance have probably induced a ranking bias. Those results consistent with the literature have suggested that the SNDS was reliable for this type of assessment.

Key messages:

- Coverage of need for palliative care was identified.
- The SNDS (French Insurance Database) was reliable for this type of assessment.

Are Cypriot community pharmacists ready to offer hypertension screening interventions? A pilot study

Romina Alexandrou

R Alexandrou[1], *C Petrou*[1], *A Peletidi*[1]
[1]Pharmacy Programme, Department of Life and Health Science, University of Nicosia, Nicosia, Cyprus
Contact: rominalexandrou@hotmail.com

Background:

Cardiovascular disease (CVD) is the leading cause of death in Europe. One of the most essential CVD risk factors is uncontrolled hypertension (HP), thus the management of HP can lead to lower CVD risk. Pharmacists (PHS) can actively contribute to various public health functions such as prevention and early detection of individuals with increased blood pressure (BP). This study aimed to assess the feasibility of a pharmacy-led HP screening programme in Cyprus.

Methods:

The study was conducted in one community pharmacy in Nicosia. The sample ($n = 87$) was randomly selected. Inclusion criteria were adults, without any CVD, diabetes or hypercholesterolemia in addition to pregnant women. BP measurements of the participants (PS) were taken. PS whose BP reading was high-normal were advised to measure their BP regularly, those whose BP reading was 140-159/90-99 mmHg were offered a home BP monitoring (HBPM) to confirm the diagnosis of HP and those whose BP reading was higher than 160/100 mmHg were referred to a cardiologist.

Results:

68 PS (78%) had normal BP, 14 PS (16%) were detected with high normal BP while 5 (6%) were identified with a BP reading higher than 140/90mmHg. 2 PS were diagnosed with HP grade 2 after PHS's referral to a cardiologist while 2 PS were diagnosed with HP grade 1 after the HBPM. An estimation of a CVD risk conducted indicated that 84% ($n = 73$) of the sample appeared to have no risk at all, 12% ($n = 10$) had low risk, 3% ($n = 3$) had a moderate risk and 2% ($n = 1$) showed moderate to high risk.

Conclusions:

The fact that 4 PS were diagnosed with HP and 14 more were given lifestyle advice can indicate Cypriot PHS' potential contribution to the prevention and early diagnosis of HP. As the sample was small and the results may not be generalised, similar programmes should be conducted with a higher number of PHS and PS in different cities in Cyprus to identify replication of the results.

Key messages:

- Cypriot pharmacists have the potential to screen individuals with high blood pressure.
- Pharmacists' intervention can lead to early diagnosis of hypertension.

Actions to improve chronic heart failure management in Paris and its suburbs, preliminary results

Michel Marty

M Marty[1], *P Nicolle*[1], *S Bataille*[2], *C Roudier-Daval*[2]
[1]Direction Régionale du Service Médical d'Ile de France, French National Health Insurance System, Paris, France
[2]Direction de l'offre de Soins, Health Regional Agency, Paris, France
Contact: michel.marty@assurance-maladie.fr

Background:

Chronic Heart Failure treatment requires close collaboration between multiple health professionals (hospitals, general practitionners, cardiologists, nurses, pharmacists,...). Guidelines for management of chronic heart failure patients after hospitalization for heart failure were published in France in 2014.

In Paris and its suburbs (Ile de France) several indicators show that improvement of processes is required especially regarding linkage between hospital and ambulatory care (for example admission rate in emergency unit was 59,7% in 2014).

Actions:

Since 2015 Regional Health Agency and Social Insurance have conducted several actions to improve patients care pathway: feed back to providers on their own results, support patients after hospital discharge, commitment of several hospitals to organize meetings with field professionals, setting up semi-urgent consultations in hospitals, bundled payment experience...

Preliminary Results:

Indicators evolution from 2014 to 2017 is favorable for rate of admission in emergency unit (57,8% versus 59,7%), 6 months mortality (20,7% versus 23,1%), hospital readmission 6 months after index admission (24,4% versus 25,2%), but unfavorable for ambulatory clinical follow up rates (general practitionner consultation within fourteen days after hospital discharge (46,1% versus 52,5%), cardiologist consultation within sixty days after hospital discharge (47,1% versus 52,8%).

Conclusions:

It is too early to assess the impact of each action and it will be difficult to conclude, because of interaction between actions. The evolution of outcome care indicators is satisfactory, which suggests the interest of acting on a whole care process. The worsening clinical follow up indicators leads to wonder about access to health care and requires an analysis by territory to adapt the actions.

Key messages:

- Actions to improve chronic heart failure management in Paris and its suburbs firsts outcomes are satisfactory.
- Acction adaptations are necessary and should be assessed in 2019/2020.

Intervention research partnerships: enablers for activating health in all policies approach?

Marion Porcherie

M Porcherie[1,3], C Bader[7], E Faure[4], A Roué le Gall[2,3], Z Vaillant[4], MF Thomas[5], S Rican[4], Z Héritage[7], J Simos[6], N Cantorregi[6]
[1]Department of Social Sciences, EHESP, Rennes, France
[2]Department of Occupational Health and Environmental Health, EHESP, Rennes, France
[3]UMR CNRS 6051, Arènes, Rennes, France
[4]LADYSS, Université Paris-Nanterre, Nanterre, France
[5]Inserm, Irset - UMR_S 1085, EHESP, Rennes, France
[6]Institut de Santé Globale, Université de Genève, Genève, France
[7]WHO French Healthy City Network, Rennes, France
Contact: marion.porcherie@ehesp.fr

Introduction:

Action on the determinants of health and equity involves the participation of all sectors, including non-health sectors. Understanding the opportunities and constraints to engage in the complex issue of health inequalities requires opening the black box of policy making. It also requires close interaction between field actors and researchers. This paper will aim to analyze the modalities of collaboration between researchers and field actors in the service of knowledge sharing, within the GREENH-City project.

Methods:

The GREENH-City project was built in an interdisciplinary and intersectoral manner and involves close collaboration with the WHO French Healthy Cities Network (FHCN). Its objective is to characterize the most promising health interventions in all policies at the city level to promote equity through green space policies. Based on the knowledge sharing model and the theory of diffusion of innovations, we will analyze how this research allows initiating collaborations between the different municipal sectors on health issues.

Results:

The intervention nature of the project seems to help the dissemination of collaborations, particularly between health services and green space services within the cities of the FHCN. The analysis, using theoretical models, of the body of empirical data collected from cities will make it possible to identify the levers and collateral effects activated by the research project.

Discussion:

The GREENH-City project was built on the basis of an interventional research framework. This choice was made precisely because of the interaction it induces between researchers and practice environments. Initial empirical results suggest that it promotes the dissemination of knowledge, a necessary first step in the evolution of practices. Indeed, the effective appropriation of research results can only be assessed in the long term and must take into account the contextual elements specific to each FHCN involved in the research.

Key messages:

- Implementation of interventional research helps to engage fields collaborations.
- Health in all policies may be supported by a research project at the local level.

Medical students' involvement in health policy: current focus and trend

Kubilay Kaymaz

K Kaymaz[1]
[1]School of Medicine, Koc University, Istanbul, Turkey
Contact: kkaymaz@ku.edu.tr

Background:

European Medical Students' Association (EMSA) and International Federation of Medical Students' Associations (IFMSA) are two leading student organizations advocating for better health in Europe and the World. How student organizations support global public health policy and particularly which topics students place greater emphasis on are not documented, although it is crucial to understand their involvement and areas of interest.

Methods:

Data on the valid policy documents of the last three years until April 2019 were retrieved from the official websites of EMSA and IFMSA. These documents were categorized using abstract submission tracks of the 12th European Public Health Conference.

Results:

Twenty-nine policy documents were retrieved, ten of which were from EMSA and 19 from IFMSA. Fourteen of all 22 abstract submission tracks (63.6%) were covered by these policy documents. Of all policy documents, 20.7% fell under the track of 'infectious diseases, preparedness and vaccines'. Most commonly advocated topic in policy documents of IFMSA was infectious diseases and vaccines, whereas that of EMSA was healthy living and health promotion.

Conclusions:

Medical students often take part in health policy by conveying their perspectives and calling other stakeholders to action via their policy documents. Policy documents of IFMSA were more related to global health challenges such as infectious diseases while special concerns in Europe such as healthy living and health promotion dominated EMSA's policies. In the near future, more student advocacy work on climate change, noncommunicable diseases and primary health care would be expected in accordance with 'ten threats to global health in 2019' announced by the World Health Organization.

Key messages:

- Medical student organizations, EMSA and IFMSA, are important stakeholders in health policy.
- The focus of their policy documents differs, and this trend is influenced by changing public health challenges in Europe and the World.

Energy policy as a social determinant of Australian health equity

Colin Macdougall

C MacDougall[1], T Delany-Crowe[1], F Baum[1], M Fisher[1], M McGreevy[1]
[1]Southgate Institute for Health, Society and Equity, Flinders University, Adelaide, Australia
Contact: colin.macdougall@flinders.edu.au

Background:

Intersectoral action on social determinants of health to reduce health inequities requires policy research beyond the usual social and human services. We ask how Australian energy policy affects health equity.

Methods:

Document analysis and policy case studies on how goals, objectives and strategies of all Australian energy policies address equity.

Results:

Energy policy affects health via risk from unreliable energy; difficult transitions to renewables; disproportionate effects on poorer people faced with high energy bills versus other basics; ecological degradation; cost pressures on businesses and governments; job losses and policy paralysis about renewable energy and climate change. Policy features subsidies for the disadvantaged; privatisation and artificial markets; differing geographical distribution of resources and high level political conflict about whether it can deliver on 3, or only 2, of the 'energy trilemma' of reliability, affordability and ecological sustainability. Mining, industrial and political interests, powerful enough to orchestrate the downfall of Australian prime ministers, actively close policy links between health, climate change and energy. Bridging energy and health policy requires political support for market solutions involving renewables; community generation of renewable energy; solutions for rural and remote areas; and global treaties. Intergenerational equity is a strong policy lever.

Conclusions:

Health in All Policies approaches can creatively engage with the language and concepts of energy policy via the daily conditions of living, inequity and climate change. When it is difficult to engage, researchers can connect with non-government organisations who bridge sectors through simultaneous advocacy for equitable health, climate and energy policies.

Key messages:

- Powerful interests burn bridges between health equity and energy policy.
- Local and global policy levers harmonising terminology differences build bridges between energy, climate change and health equity.

Basic problems in conducting a general preventive review of persons over 18 years of age in Bulgaria

Penka Stefanova

P S Kostadinova[1], S D Kostadinov[2], I Y Stoilova[3], S L Georgieva[4], M S Kamburova[4], S K Ivanova[5]

[1]Regional Health Insurance Fund, Pleven, Bulgaria
[2]Department of General Medicine, Forensic Medicine and Deontology, Faculty of Public Health, Medical University of Pleven, Pleven, Bulgaria
[3]Department of Hygiene, Medical Ecology and Occupational Diseases, Faculty of Public Health, Medical University of Pleven, Pleven, Bulgaria
[4]Department of Public Health Sciences, Faculty of Public Health, Medical University of Pleven, Pleven, Bulgaria
[5]Pleven, Bulgaria
Contact: pstefanova_pl@abv.bg

Background:

In Bulgaria, following the reforms in healthcare, the Health insurance model and the role of GPs have been adopted as a key figure for primary outpatient medical care. Part of the obligations of the GPs for the implementation of the individual contracts with RHIF are also the preventive examinations of the mandatory health-insured persons over the age of 18 and the formation of risk groups of the population. Since 2006, the overall prophylactic review is mandatory for all health insured persons over the age of 18, regardless of their health status. It includes a core set of activities and studies that identify both people with disabilities and patients at increased risk of developing certain socially significant diseases such as cardiovascular, malignancies and diabetes.

Material and methods:

Data were collected by documents review and direct individual self-administered questionnaire among 513 persons from the Pleven region and 229 GPs from three districts in the country.

Results:

Despite the mandatory nature of general checkup for all persons over '18, annually recognizes low range (from 35.8 to 45%). It was found that people over 65 who have chronic diseases more regularly visit the GP for check-up. The main reasons for the low population coverage are: lack of time and motivation of GPs; high relative share of persons with discontinued health insurance rights (over 20%); insufficient awareness and dissatisfaction of the mandatory health insured persons about mandatory prophylactic examinations. Of the respondents, 48% do not know what activities are involved, and 39% consider that the reviews are carried out formally.

Conclusions:

Prevention of health-insured persons over 18 years of age is low in scope and is mostly opportunistic. In order to optimize the health and economic impact of the prophylactic review program, it is appropriate to provide for motivation measures for both GPs and those subject to the scope.

Key messages:

- In Bulgaria, the range of persons over 18 years old with prophylactic examinations is low.
- Prophylaxis of the persons covered is mostly opportunistic.

Development of an evidence-based reference framework for care coordination interventions in France

Françoise Colombani

F Colombani[1,3], G Encrenaz[1], B Quintard[2], M Sibé[3,4], A Ravaud[1,5], F Saillour-Glénisson[3,4,6]

[1]Centre de Coordination en Cancérologie (3C), CHU de Bordeaux, Bordeaux, France
[2]Faculté de Psychologie, Laboratoire EA 4136, Université de Bordeaux, Bordeaux, France
[3]Equipe Economie Management des Organisations en Santé (EMOS), Centre INSERM U1219-Bordeaux Population Health, Bordeaux, France
[4]ISPED-Bordeaux School of public Health, Université de Bordeaux, Bordeaux, France
[5]Pôle de Cancérologie, Département d'Oncologie Médicale, CHU de Bordeaux, Bordeaux, France
[6]Pôle de Sante Publique, Service d'Information Médicale, CHU de Bordeaux, Bordeaux, France
Contact: francoise.colombani@chu-bordeaux.fr

Background:

Today, the high variability of practices, the lack of common definitions and underlying concepts increases the existing difficulty to standardise, to replicate, to transpose and to assess the coordinated care. This heterogeneity makes very difficult the evaluation of performance of care coordination. The aim of the first phase of Epock study is to develop a theoretical framework for care coordination interventions in the French health system that can be used for description, implementation and evaluation of care coordination intervention in any clinical situation.

Methods:

A review of systematic reviews on care coordination interventions was conducted to identify relevant models and constitutive elements of the expected reference framework for care coordination intervention. These elements resulting from the literature review have been grouped by themes, prioritised and selected by a structured consensus method (Nominal Group Technique).

Results:

Four dimensions of care coordination were identified: (a) Underlying conceptual models; (b) Care organization, care and facilitation activities; (c) Actors and tools; and (d) Effects classified according to WHO's quality of care dimensions. Among these dimensions, 4 to 28 elements have been selected to build the reference components of care coordination in France.

Conclusions:

This first reference framework for care coordination interventions in France will be used during the Epock project phase 2 as a basis for comparing practices observed in oncology. This framework could be used as of now for: practice by helping to develop job descriptions and training programmes for future care coordination professionals; piloting to measure care coordination (by developing indicators for care coordination); and research, to evaluate the impact of care coordination interventions.

Key messages:

- Epock is a challenging French national research project for the development of an evidence-based reference framework for cancer care coordination interventions considered as a complex intervention.
- Epock will provide key elements for cancer care coordination intervention effective implementations and for designing further medico-economic evaluation of cancer care coordination intervention impact.

Evaluation of the health pathway through the patient-experience in the French program PAERPA

Valérie Donio

V Donio[1], MM Defebvre[2], R Pamart[1], B Caron[3], C Delval-Bugny[4], D Dambre[5], C Di Martino[6], JB Beuscart[6]
[1]Public Health Department, CEMKA, Bourg-la-Reine, France
[2]Chargée de Mission Vieillissement, ARS Hauts-de-France, Lille, France
[3]Chargée de Planification Politique Personnes âgées, ARS Hauts-de-France, Lille, France
[4]Chargée de Mission PAERPA, ARS Hauts-de-France, Lille, France
[5]Gériatre et coordinatrice du projet PAERPA du Valenciennois, CH Saint Amand Les Eaux, Saint Amand Les Eaux, France
[6]Santé Publique: Epidémiologie et Qualité des Soins, Université de Lille, CHU Lille, EA2694, Lille, France
Contact: valerie.donio@cemka.fr

The patient-experience is an emerging concept in research and medico-social action, and its consideration in the development of care pathways is encouraged (e.g. 'Ma Santé 2020' national plan in France). In addition, the patient-experience of the elderly subject has specific dimensions and his collection presents difficulties insufficiently explored. PAERPA (elderly people at risk of loss of autonomy), French national experiment for the care of frail elderly patients, offers an opportunity to return to these issues.

The objective of this study, mandated by the ARS of Hauts-de-France, was to collect the experience of the elderly PAERPA. Faced with the difficulties of current methodologies, several methodological approaches have been combined: semi-structured individual interviews face-to-face or by telephone, dedicated questionnaire. In addition, a specific grid was developed to explore the home-based patient experience, including seven dimensions of the patient-experience identified in the literature. This study was conducted in the second half of 2018 (3 years and a half of the start of the project).

The experience of 43 seniors and / or caregivers was collected. Patients PAERPA are generally satisfied with their care but they have difficulties in making the link between their care and the actors and devices specific to PAEPRA experimentation. Human connection and listening seem essential for the elderly patients included. Other dimensions, such as stakeholder coordination, remain controversial and more difficult to grasp. Methodologically, the particular situation of seniors, such as sensory or memory disorders, requires a major adaptation of the survey tools.

In PAERPA, the patient-experience of the frail elderly subject passes mainly through the feeling of a human connection. Current methodologies do not seem fully adapted to collectively capture the experience of frail elderly patients.

Key messages:

- Evaluating the patient-experience to improve the health pathway is possible and necessary through a qualitative collection, regularly, in itinere.
- The peculiarities of older people often require the participation of carers, who need to be involved in the assessment of the patient-experience and raised awareness.

Colorectal Cancer Screening Programme: Algarve Preliminary data

Maria Filomena Correia

M Correia[1,2], M Cancela[2], P Caldeira[4], J Morera[3], C Cardoso[1], R Pereira[1], D Ferrinho[1], L Vale[1]
[1]Nucleo de Rastreios, ARS Algarve, Faro, Portugal
[2]Public Health, ARS Algarve, Faro, Portugal
[3]Anatomia Patologica, CHUA, Faro, Portugal
[4]Gastroenterologia, CHUA, Faro, Portugal
Contact: filomenahcorreia@gmail.com

Problem:

The burden of disease for oncological problems is significant in Portugal. Population-based screenings, such as colorectal cancer screening (CCS) with faecal occult blood tests (FIT) is a priority program to reduce the burden of disease and a cost-effectiveness measure.

Description problem:

Algarve CCS started in 2017,to early detect colorectal cancer reducing morbidity and mortality. Screening strategy to detect and remove cancer precursors (adenomas) and early cancer detection with less invasive treatment using a non-invasive stool test was selected. A quantitative faecal immunochemical test for haemoglobin (FIT) with higher sensitivity for adenoma and cancer, specific for human globin with no dietary restriction, with a single sample screening is considered a test with higher participation. Target population all gender from 50 to 75 are invited to participate in the CCS by letter. Screening interval is 2 years and FIT cut-off- 117 (ng Hb/mL). Software was used to manage all CCS. Health units distribute the test and a flyer. All FIT-positive were invited to do a full colonoscopy at University Hospital.

Results:

A preliminary descriptive analysis (2017/2019) was made. After exclusions 25017 of target population participate 34,4%(n = 8594),27.5%(n = 6883) submitted it for analysis, 3.9% (n = 266) had positive FIT and were invited for a full colonoscopy with 57.5% (n = 153)participation rate. Cancer detection was 0.9‰ and adenomas detection rate was 9.9%. FIT positive with colonoscopy 3.9% (n = 6) had carcinoma and 44.4% (n = 68) had adenoma.

Lessons:

Some operational changes were made to improve participants and professionals adherence to CCS. Pathology observed in the positive cases, reinforce the need to implement strategies to increase literacy, raise public awareness, keep the screening test and improve accessibility of health facilities.

Key messages:

- The importance of a colorectal cancer early diagnosis prevent aggressive interventions in a precancerous phase.
- The importance of a colorectal cancer early diagnosis improves survival and population quality of life.

Alcohol and cancer: risk perception among the French population

Raphaëlle Ancellin

R Ancellin[1], C Cogordan[2], JB Richard[2], R Andler[2], A Deutsch[1]
[1]Prevention, INCa, Boulogne Billancourt, France
[2]Health Promotion and Prevention, Sante Publique France, Saint Maurice, France
Contact: rancellin@institutcancer.fr

In 2015, in France, 41 000 deaths were estimated to be attributable to alcohol consumption including 16 000 deaths from cancer. 8% of all new cancer cases were attributable to alcohol. The French National Cancer Institute and Sante Public France have conducted a study on knowledge and opinions of the French population on the risks factors attributed to cancer, including alcohol consumption.

Data came from the 2015 Barometre Cancer survey, a random cross-sectional telephone survey of the French general population (n = 3771 individuals aged 15-85 years). About 88% of the respondents felt well informed about the risks of alcohol. Opinions show an important risk denial and risk relativization: e.g, 85% agreed that the principal risk with alcohol consumption are traffic accidents or violence and 75% agreed that soda and hamburgers are as bad as alcohol for the health. Those perception were higher among men, older respondents, daily drinking consumers and those of low socioeconomic status. Population's beliefs to deny the cancer risks due to alcohol use are common in France.

These results can be used to redesign public information about the risks of alcohol.

Key messages:

- Population's beliefs to deny the cancer risks due to alcohol use are common in France.
- It's necessary to adress public information about the risks of alcohol.

Algarve Cervical Cancer Screening Programme

Maria Filomena Correia

M Correia[1,2], A Pacheco[4], J Morera[3], R Pereira[1], D Ferrinho[1], L Vale[1], C Cardoso[1]
[1]Regional Screening Management, ARS Algarve, Faro, Portugal
[2]Public Health, ARS Algarve, Faro, Portugal
[3]Anatomia Patologica, CHUA, Faro, Portugal
[4]Gynecology, CHUA, Faro, Portugal
Contact: filomenahcorreia@gmail.com

Issue:

Cervical Cancer (CC) is the 7th most frequent and the 2nd most common in women. The standardized mortality rate, in Portugal is 2.3/100000 inhabitants and Algarve is the region with highest rate, 4.9/100000.

Description:

Programme started in 2010. Population-based screening programme can reduce incidence, mortality and morbidity with an early diagnosis, preventing aggressive interventions in precancerous phase, improving survival and life quality. Target population, woman age 25-64.are invited to primary test liquid-based cytology (ThinPrep) every 3 years. Health Centres are responsible for select, invite, collect samples and send to Hospital laboratory. For positives, a cervical pathology consultation is required. National Guidelines now indicates DNA testing for human papillomavirus (HPV) as primary screening test, each 5 years, to woman age 25 to 60 and screening program changes will be implemented in 2019 with improved response time and lower cost.

Results:

Since 2010 the target population has increased 12% every 2 years and the adhesion rate increased ≈68% and≈108%. Nevertheless the 3rd cycle has showed 10,8% (17.975) adhesion rate. Most women 16.112 (89.6%) had a negative diagnosis, 503 (2,8%) is ASC-US + (HPV test), and 761(4,2%) had a cervical pathology consultation. From those, 117 (15.4%) had a LSIL, 69 (9,1%) HSIL and 2(0,3%) cancer. Cancer detection rate is 0,1 ‰.

Lessons:

The small adhesion rate particularly by aged women, the users unfriendly Information System and direct screening health units management are some of the issues that requires improvement. Also population literacy, self-sampling vaginal fluid and clinical meetings are some of the options to improve screening program.

Key messages:

- Cervical Cancer early diagnosis prevent aggressive interventions in a precancerous phase, improves survival and life quality.
- Better access and health communication are major points in screening programs.

Predictors of a high work participation in the flexi-job scheme: a regional Danish cohort study

Ditte Munkedal

D Munkedal[1], N Weye[2], K Fonager[1,3]
[1]Department of Social Medicine, Aalborg University Hospital, Aalborg, Denmark

[3]Department of Clinical Medicine, Aalborg University, Aalborg, Denmark
Contact: ditte_louise@hotmail.com

Background:

In Denmark, people with permanent and significant reduced work capacity can be assigned to a flexi-job (FJ) scheme. In 2013, the social security policy for FJ was reformed in order to improve the chances for employment for people with reduced work capacity. In a Danish cohort study from the North Denmark Region we aimed to describe work participation in the flexi-job scheme before and after the reform. Furthermore, we described the associations between employment in the flexi-job scheme and predictors such as sociodemographic factors, healthcare use, and work participation before assignment.

Methods:

The study population included individuals assigned to the FJ scheme between 2010 and 2015 in the North Denmark Region. The study population was followed until leaving the FJ scheme or end of follow up (September 2017). Baseline information included data on sex, age, place of residence, number of contacts to specialized healthcare, and number of working weeks five years before. Work participation score (WPS) was defined as number of working weeks divided with the total number of weeks in the FJ scheme. High WPS was defined as above the median. We used a logistic regression model to study associations between baseline characteristics and high WPS.

Results:

A total of 4,668 people were included in the study. The overall median WPS were 73% (interquartile range (IQR) 42% - 90%). Policy changes (OR 1.40, 95% confidence interval (CI): 1.24 - 1.59), male sex (OR 1.16, CI:1.03 - 1.31), young age (OR 1.45, CI: 1.17 - 1.80), urban living (OR 1.22, CI:1.03 - 1.46), no contact to specialized healthcare (OR 1.54, CI: 1.21 - 1.99), and a strong association to the labor market before awarded FJ (OR 4.25, CI: 3.34 - 5.41) were all predictors of a high WPS during FJ-scheme.

Conclusions:

Policy changes increased work participation in the FJ-scheme. However, the strongest predictor of a high WPS for people awarded FJ was the degree of work participation before the scheme.

Key messages:

- Several factors had impact on work participation in a flexi-job scheme.
- The flexi-job scheme might be insufficient to secure employment for people with prior weak affiliation to the labor market.

Adolescents' alcohol use after liberalisation of alcohol sales in Finland in 2018

Arja Rimpelä

A Rimpelä[1,2], P Lindfors[1], JM Kinnunen[1], AH Katainen[3]
[1]Faculty of Social Sciences, Health Sciences, Tampere University, Tampere, Finland
[2]Department of Adolescent Psychiatry, Tampere University Hospital, Tampere, Afghanistan
[3]Social and Public Policy, University of Helsinki, Helsinki, Afghanistan
Contact: arja.rimpela@tuni.fi

Background:

Adolescents' alcohol use and binge drinking decreased in Finland since 2001 while the proportion of those who did not drink, increased until 2017. The 2018 Alcohol Act (entered 1 March) allowed retail stores sell all alcoholic beverages containing up to 5.5% alcohol by volume (previously 4.7%, beer and cider). Alcopops, assumed popular among adolescents, are now available in retail stores for those ≥18 years. We study changes in adolescents' alcohol use and type of alcohol beverages until 2019.

Methods:

Data from Adolescent Health and Lifestyle Survey (AHLS) has been collected biennially from nationally representative samples of 12-, 14-, 16- and 18-year-old Finnish adolescents. The data collection of the 2019 survey is going on and continues until June. Approximately two thirds of the expected responses (N = 2666) has arrived by the end April.

Results:

According to our preliminary results, among girls abstinence slightly decreased from 2017 to 2019 and the increasing trend levelled off. Among boys, abstinence stayed at the same level from 2017 to 2019 among 12- and 14-year olds, decreased among 16-year-olds and increased among 18-year-olds. The decrease in monthly alcohol use had levelled off in 2017 and the use stayed approximately on the same level in 2019 as in 2017. Changes in type of alcoholic beverages will be ready in June and will be presented in the conference.

Conclusions:

One year after the liberalisation of the Alcohol Act, no increase in adolescent alcohol use was observed, but the decreasing trend seems to have levelled off, while a small decrease in the proportion of those who do not drink at all seems likely.

Key messages:

- In a short run under-aged alcohol use has not increased after the liberalisation of the Alcohol Act.
- However, abstinence has slightly decreased.

Regional variations of amenable mortality rate in Latvia

Jolanta Skrule

J Skrule[1,2], *J Lepiksone*[1]
[1]Research and Health Statistic Department, Centre for Disease Prevention and Control, Riga, Latvia
[2]Public Health Association of Latvia, Riga, Latvia
Contact: jolanta.skrule@spkc.gov.lv

Background:

Death can be considered as amenable if all or most deaths from that cause (at certain age group if appropriate) could be avoided through optimal quality of health care. Amenable mortality is one of indicators to use for assessing health system performance and outcome.

Methods:

For amenable death causes using list of diseases and conditions from Office for National Statistics of United Kingdom (used by Eurostat). Calculation of amenable death rate (per 100000 population) for ages 0 to 74 years at regional level (six statistical regions) for time period 2015-2017, direct age-standardization to the overall national population. Results accompanied by confidence intervals (95%).

Results:

There is a slight decline in amenable mortality of Latvia at national level over the period 2015-2017. Amenable death rate of Latvia in 2017 was 309 per 100 000 (95% CI, 308.95 - 309.05). Death rates at regional level varies from 274.34 (274.23 - 274.44) in Pieriga region to 375.49 (375.37 - 375.62) per 100 000 in Latgale region. There are no significant changes in ranking of regions for three years period.

Conclusions:

Results shows that there are differences of amenable mortality rates between regions of Latvia. There are health inequalities between regions: Pieriga region show the best health care services performance, while Latgale displays the worst performance. There is field for deeper analysis and find better interventions for improvements at national level and reducing variability between regions.

Key messages:

- There are regional variations of amenable mortality in Latvia.
- Regional variations show places to reduce health inequality.

1st European Academy for Healthcare Leaders: high training on leadership to manage health systems

Leonardo Villani

L Villani[1,2], *EM Frisicale*[1,2,3], *P Parente*[1,2,3], *P Cacciatore*[1,2], *E Carini*[1,2], *A Gentili*[1,2], *A Grossi*[1,2], *AM Pezzullo*[1,2], *C Favaretti*[1,2], *W Ricciardi*[1,2,4]
[1]WHO Collaborating Centre for Health Policy, Governance and Leadership in Europe, Rome, Italy
[2]Public Health Department, Università Cattolica del Sacro Cuore, Rome, Italy
[3]Local Health Authority, ASL Roma 1, Rome, Italy
[4]Women's and Children's Health Sciences and Public Health, Fondazione Policlinico A. Gemelli, Rome, Italy
Contact: leonardovillani92@gmail.com

Background:

Nowadays having leadership skills is critical to manage healthcare systems. The World Health Organization Collaborating Centre on Health Policy, Governance and Leadership organized the 1st European Academy for Healthcare Leaders in Rome from 15th to 17th November 2018. Senior officials of the Ministries of Health of 16 Members Countries of the WHO European Region attended and actively participated to the event, led by experienced Italian and European experts. The Academy could be considered a moment of high training on leadership and governance of health systems.

Objectives:

The event was aimed at creating effective networks among participants to share ideas and strategies to improve leadership skills, providing practical tools to be applied in healthcare systems and to develop a common and transferrable leadership framework in Europe. Frontal lectures and interactive workshops covered three main areas: leadership skills, current challenges of health systems and sustainability of health systems today.

Results:

The 3-days event gave the opportunity to discuss the main issues in Public Health highlighting how to be an effective leader in healthcare. Leadership should enable the translation of knowledge into productive action pathways, providing health equity and improving population's health. At the end of the event, participants filled a survey and the results showed high satisfaction about contents (100% out of 16 participants).

Conclusions:

Health systems need to change in order to face the formidable challenges of our times. This event empowered the participants in order to support the creation of strategies and to develop leadership tools to apply at country level. The experiences, ideas and good practices shared during this event strengthened a collaborative network and have been useful to identify common goals and solutions.

Key messages:

- These kinds of events are fundamental to improve knowledge about leadership in healthcare.
- Leadership should have a major role to play in healthcare worldwide.

A framework to help defining relevant preventive actions in multi-professional health care centers

Baptiste Pluvinage

B Pluvinage[1,2,3], *F Dugué*[3], *D Dépinoy*[3]
[1]Université Paris-Diderot, Paris, France
[2]Assistance Publique-Hôpitaux de Paris, Paris, France
[3]Acsantis, Paris, France
Contact: pluvinage.baptiste@gmail.com

For more than 10 years in France, multi-professional healthcare centers have been considered as innovative organizations, which offer attractive work conditions for health professionals and help to structure primary care. Their development is strongly supported by public policy (e.g. specific funding methods, a target of 2000 teams by 2022) and is seen as a mean to enhance preventive actions.

From a public health perspective, when professionals define their collective project, preventive actions should be chosen according to their relevance (by considering local population needs), effectiveness (based on evidence) and realism (in terms of implementation). Our goal was to make an inventory of existing tools and recommendations but also to propose a framework that considers the actual practicing conditions of French primary care teams. Three methods were used: a bibliographic study, feedback from a consulting firm with a 10 years' experience in supporting new teams in defining their multi-professional project, and interviews from experts and health professionals.

Due to professional training and practice, preventive actions are less familiar to professionals when they are not integrated into individual and curative cares. Indeed, most existing recommendations are designed from a macroscopic point of view, dismissing the particularities of multi-professional private practice. Thus, we could identify 9 categories of factors likely to determine the relevance of a preventive action, including a specific context-population-team setting. Although this is an exploratory work, feedback from professionals confirms the potential positive or negative influence of these items on the implementation of an action.

Our framework could be converted into a tool consisting of a list of questions to ask before primary care teams choose a preventive action to implement. Frequent assessments should be carried out and shared in order to develop empirical and reliable knowledge in this field.

Key messages:

- Despite a strong public policy to develop multi-professional health care centers in France, recommendations about preventive actions insufficiently consider specific conditions of practice.
- Mixing theoretical and practical perspectives, our framework could help to improve the relevance, effectiveness and realism of preventive actions considering a specific context-population-team setting.

Government-based financing strategies for public health in Ukraine: way of transforming

Nataliia Kovalenko

N Kovalenko[1], M Duda[1], V Liashko[2]
[1]USAID/Health Reform Support Project (Deloitte), Kyiv, Ukraine
[2]Center for Public Health of Ukraine, Kyiv, Ukraine
Contact: nkovalenko@hrs.net.ua

Since 2016 Ukraine is going through health financing reform. National public health (PH) system functioned with focus only on control of epidemics and sanitary situations. Following EU recommendations, the Government established Center for Public Health (CPH) and adopted the Concept of PH System Development. As new Budget Code comes into force in 2020, PH system must be transformed on institutional and financing level.

We conducted policy analyses and developed PH financing options and found that existing budget programs (epidemiological surveillance and purchases of medicines) make up over 70% of the total government PH spending. Public spending was ineffective based on line budget approach without attention to quality and not linked to epidemiological situation. New PH mechanisms will be piloted in 2019 in several regions to calibrate approach and ensure evidence-based policy. Transformed financing model focuses on purchasing PH services rather than maintenance.

We selected a phased approach to launch new PH financing mechanism. Procurement system ProZorro allows to follow transparency and good governance principles while purchasing PH services. Using experience with GF's procurements, the CPH will purchase services: HIV and hepatitis prevention among key population, supporting PLWHIV, epidemiological surveillance. Legal framework developed and agreed with stakeholders. This approach allows to shift focus from dealing with consequences to prevention and early revealing of potential PH risks. Provider's staff and network will be optimized. Budget economy is up to 15% in 2019, and additional 5% in 2020.

The rebuilding PH system showed that 2019 is an opportunity to develop and pilot new financing approaches. Key step is to ensure that national policy equipped with legislation and recommendations to implement new PH approaches. Pilot results will become a strong base for further PH system development as well as evidence-based policy for effective response to PH needs.

Key messages:

- Public health system in Ukraine is going through reforming process to address existing challenges and introducing new financing approaches with a focus on regional level.
- Using transparent procurement system to transform the public health financing mechanisms due to existing limitations and overall health financing reform in Ukraine.

Perceptions of barriers and levers to health-enhancing physical activity policies in French cities

Anne Vuillemin

A Noël Racine[1], JM Garbarino[1], K Corrion[1], F d'Arripe-Longueville[1], B Massiera[1], A Vuillemin[1]
[1]Université Côte d'Azur, LAMHESS, Nice, France
Contact: anne.vuillemin@univ-cotedazur.fr

Background:

Policy is one of the levers to initiate structural change to foster the promotion of Health-Enhancing Physical Activity (HEPA). To this end, policymakers have to deal with complex ecosystems embedded in specific contexts. However, limited research has been published on this topic at the local level. The purpose of this study was to identify the barriers and levers to develop HEPA policies from the point of view of municipals managers and elected officials in mid-size French cities.

Methods:

This study was conducted following the concept mapping approach: a list of statements was submitted to 17 French mid-size cities. These statements completed the beginning of this sentence: ''In a mid-size municipality context, to develop HEPA policies, it is necessary to...''. First, key informants in each city rated the importance of each statement without considering their local context according to a Likert scale, ranging from 1 (not at all important) to 6 (extremely important). Then, they had to rate the feasibility of each statement considering their local context according to a Likert scale ranging from 1 (not at all feasible) to 6 (extremely feasible).

Results:

A total of 23 municipal managers and 10 elected officials from sport (n = 14), health (n = 10), and social (n = 9) sectors from 11 French mid-size cities participated in this study. Statements related to political commitment, shared governance and partnership appeared as potential levers to develop HEPA policies. Statements related to the economic model of the local HEPA promotion, mandate of the mayor, and land use planning appeared as potential barriers to develop HEPA policies. The results varied according to the position and the sector of the respondent.

Conclusions:

The results suggest that some local contextual factors could affect the development of HEPA policies in mid-size French cities. This study contributes to a better understanding of the development of local HEPA policies in the French context.

Key messages:

- Local contextual factors should be considered when developing health-enhancing physical activity policies.
- The perceptions of these local contextual factors varied according to the position and the sector of the respondent.

Organized colorectal cancer screening: the participation rate according to the precariousness

Sylvie Arlotto

S Arlotto[1,2], E Le Cozannet[3], Y Rinaldi[3,4], S Gentile[1,2], P Heid[3], JF Seitz[2,3,5]
[1]Service d'Evaluation Médicale, Hôpital de la Conception, Assistance Publique Hôpitaux de Marseille (APHM), Marseille, France
[2]EA 3279 Self-Perceived Health Assessment Research Unit, Aix Marseille Université (AMU), Marseille, France
[3]Centre Régional de Coordination des Dépistages des Cancers Sud PACA, Marseille, France
[4]Service de Gastro-Entérologie, Hôpital Européen, Marseille, France
[5]Service de Gastro-Entérologie, Hôpital de la Timone, Assistance Publique Hôpitaux de Marseille (APHM), Marseillea, France
Contact: sylvie.arlotto@gmail.com

Background:

The National Organized Colorectal Cancer Screening Program (DOCCR) was introduced in 2008. The participation rate in France is much lower than the European recommendations (33.5% versus 45%). There are significant disparities across France.

The objective was to assess whether there are disparities in participation rates within the Bouches-du-Rhône(BdR) department and to study the possible correlation of these geographical areas with their level of precariousness.

Methods:

Based on data collected by the ARCADES association (management structure in charge of cancer screening in the BdR region), 325,207 people in 2012 and 489,953 in 2017 were invited to participate in the DOCCR. The participation was analysed in two aspects: participation rate (TP) (test carried out) and participation rate of those who took a test or expressed a justified refusal (TPJ) (personal or family history, other test under 2 years old, colonoscopy under 5 years old). An average precariousness rate was also assessed per municipality based on 2012 INSEE data for the age group concerned.

Results:

The TP were 18.9% in 2012 and 14.4% in 2017; the TPJ were 22.8% and 16.4% respectively and differs significantly between the municipalities in the department ($p < 0.001$). The average precariousness rate observed in our population was 12.3 (±8.2). The TPJ is inversely correlated with the precariousness rate: the higher the latter, the lower the participation rate ($R = -0.58$ in 2012, $R = -0.539$ in 2017; $p < 0.05$). The average participation rate whatever the year is lower for municipalities with a precariousness rate below the median (19.2 ± 2 versus 16.9 ± 3.5 for the year 2017).

Conclusions:

Participation rates in 2012 and 2017 are lower than the European recommendations. The participation is significantly related to the average rate of precariousness; the most vulnerable participate less well. Specific actions towards the most vulnerable are to be considered in order to improve adherence to the DOCCR.

Key messages:

- The participation organized colorectal cancer screening program is significantly related to the average rate of precariousness.
- Specific actions towards the most precarious are to be considered in order to improve adherence to the DOCCR.

Caregivers of non-dependent old person: perceived loneliness is associated with poor health status

Sylvie Arlotto

S Arlotto[1,2], *S Gentile*[1,2], *AC Durand*[2], *S Bonin Guillaume*[3,4]
[1]Service d'Evaluation Médicale, Hôpital de la Conception, Assistance Publique Hôpitaux de Marseille (APHM), Marseille, France
[2]EA 3279 Self-Perceived Health Assessment Research Unit, Aix Marseille Univ (AMU), Marseille, France
[3]INSERM, INS, Inst Neurosci Syst, Aix Marseille Univ (AMU), Marseille, France
[4]Internal Medecine and Geriatric Departement, Assistance Publique Hôpitaux de Marseille (APHM), Marseille, France
Contact: sylvie.arlotto@gmail.com

Objectives:

Informal care has poor effects on caregivers' health status. Several studies targeted informal caregivers of dependent or severely ill old persons. But, few of them analysed non-dependent old persons caregivers and their perceived loneliness. We hypothesized that perceived loneliness is an independent factor that worsen the caregiver burden and perceived health status. The aim of this study is to analyze factors associated to the perceived loneliness of caregivers of the non-dependent old persons.

Methods:

A Cross-sectional study has been conducted among 876 dyads. Old persons over 70 years of age, non-dependent, living at home and their caregiver eligible for social support by retirement and occupational health insurance in South-east of France were included. Caregivers were assessed by the Mini-Zarit Scale for the burden, and with 5-point -Likert scales for loneliness and perceived health status. A multivariate logistic regression model was performed to analyze explanatory variables related to loneliness.

Results:

Characteristics of the caregivers were: 64.5% female, 29% spouse, 61% children; 64% with frailty and 38% with high burden, 10.5% of them felt often or always lonely. Loneliness was positively associated to (OR; CI 95%): caregiver's poor health status (3.40; 1.60-7.23), burden (4.06; 1.99-8.27), sleep disorders (3.75; 1.85-7.60), anxiety (6.64; 3.23-13.65) and a bad relationship with the old persons (2.17; 1.11-4.25). Loneliness was negatively associated to a good family support (0.33; 0.17-0.63) and living alone (0.34; 0.16-0.76).

Discussion:

Loneliness should be differentiated from social isolation. Caregivers loneliness is not very frequent but highly correlated to a poor health status perception. Thus, it is essential that health care providers assess for caregivers' perceived loneliness to implement specifics supporting actions to improve health status.

Key messages:

- Caregivers loneliness is not very frequent but highly correlated to a poor health status perception.
- It is essential that health care providers assess for caregivers' perceived loneliness to implement specifics supporting actions to improve health status.

Personalized Care Plan for non dependent old persons decrease significantly caregivers' burden

Sylvie Arlotto

S Arlotto[1,2], *S Gentile*[1,2], *AC Durand*[2], *S Bonin Guillaume*[3,4]
[1]d'Evaluation Médicale, Hôpital de la Conception, Assistance Publique Hôpitaux de Marseille (APHM), Marseille, France
[2]EA 3279 Self-Perceived Health Assessment Research Unit, Aix Marseille University (AMU), Marseille, France
[3]INSERM, INS, Inst Neurosci Syst, Aix Marseille University (AMU), Marseille, France
[4]Internal Medecine and Geriatric departement, Assistance Publique Hôpitaux de Marseille (APHM), Marseille, France
Contact: sylvie.arlotto@gmail.com

Objectives:

Informal care provided by family caregivers in old persons is associated to a high risk of burden and poor health status. This study aimed to analyze the impact of a Personal Care Plan (PCP) attributed to non dependant old persons living in the community on caregiver burden, satisfaction and frailty.

Methods:

This non interventional longitudinal study was performed in the south East area of in France: olds persons asking for a PCP (>70 years old, with no disability and no severe chronic disease, living at home) and their caregiver were included with a 6-months follow up. Dyads were visited at home by social workers. Caregivers Burden has been assessed with Mini-Zarit and frailty status with FiND (Frail Non-Disable).

Results:

876 dyads (old persons: female 77.6%, aged 82.2 ± 5.8 years old; caregivers: 64.5% female, 29% spouse, 61% children; 64% with frailty and 38% with high burden; high burden being significantly associated with frailty) were eligible for a PCP. Among them, 564 PCP were financed, mainly: housekeeping and meal preparation. For those old persons who had PCP, near half of their caregiver decreased the time spent to these activities. With the PAP, 88% of the caregiver had a lower burden level, only 6% had a persistent high burden; 61,5% were totally satisfied. Frailty status was not modified.

Discussion:

Our study highlight that the burden occurs also in non dependent old persons's caregivers. Social support implementation for activity of daily living had a major impact on the burden but not on the caregiver frailty, which means that determinants of caregiver's frailty are more complex and further studies are needed.

Key messages:

- Social support implementation for activity of daily living have a major impact on the burden; the burden occurs also in non dependent old persons's caregivers.
- Personalized plan implemented to support activity of daily living improve caregiver burden even in non-dependent old persons.

Mutual Learning in Cancer Control Policy Implementation: Interviews With Local Policy Makers

Laure Bakker

L Bakker[1], *R Kiasuwa Mbengi*[1]
[1]Cancer Center, Sciensano, Brussels, Belgium
Contact: laure.bakker@sciensano.be

Many policy recommendations in the field of cancer control are developed at the EU level, but insights on the practical implementation are lacking. However, European Member States encounter similar barriers when implementing and could learn from each other. Our aim is to facilitate this, through a mutual learning platform, developed in the framework of the EU Joint Action on Cancer Control, iPAAC.

A first step is to collect examples of implementation experience in the field of prevention, screening, diagnose and treatment, organisation of care and cancer information systems and to identify the key contextual features of the country (legal framework, healthcare systems, etc.). Therefore, in-depth interviews with national policy makers, administrators and experts of 20 EU Member States are carried out. A second step is to translate their experiences into factsheets, which will the core of the mutual learning platform.

Two types of examples of experiences came up: firstly, implementation plans or frameworks and secondly, practical solutions to implementation challenges. These last relate to different barriers encountered: the industry lobbies; stakeholder's involvement; avoid and tackle social inequalities; evaluation of programs; introduction and financing of innovations, digitalization, organization of the health care system, etc. The results also include a series of reported challenges for which further policy support or knowledge is needed.

The results clearly show that similar challenges exist and are solved in different EU countries. Through translating the examples of implementation experience into factsheets, countries can learn from each other. Besides the factsheets, the mutual learning platform will provide contextual features which allow and support translation into the local context.

Key messages:

- By conducting in-depth interviews with health policy makers, common challenges in the implementation of cancer control policy, as well as solutions to overcome them, came up across EU Member States.
- Through the provision of concrete examples on how to overcome implementation barriers, we facilitate mutual learning between the EU Countries to improve cancer control and benefit to public health.

Do modern dental care systems adequately meet the health needs of citizens? Poland comparing to EU

Joanna Kobza

JK Kobza[1]
[1]School of Public Health, Public Health Department, Bytom, Poland
Contact: koga1@poczta.onet.pl

Background:

residents of highly developed countries do not have universal access to dental care at a level corresponding to the current needs, that results from the ongoing socio-economic, health and demographic changes. Dental care is fragmentary, covers only selected population groups, by far the largest negligence is in the field of prevention. Poland is an example of bad oral health status, where dental caries index for adolescents in all ages groups has been the highest in Europe.

Objective:

The aim of this study was to carry out an analysis of some organizational, financial and social aspects of a dental care in Poland, comparing to EU countries, and to identify the main causes of a bad oral health outcomes.

Material and methods:

This research presents findings from the 610 dental providers interviews, carried out in 2018. The survey consisted of 32 questions, concerning all relevant aspects of dental clinics activity. Statistical analyzes were performed in a SAS package - 9.4 version.

Results:

Poland has the highest number of dentists in EU (9.9 per 100 thou. of population) while the average for EU is 6.6. Dental rooms are modernly equipped. Dentists apply the newest technologies, they are constantly improving their knowledge and implement the TQM tools. Less than 30 % of patients are treated in public system, the average waiting time for the appointment in public sector is three times longer than in private one. Dentists perform the care of young people mainly in the area of conservative dentistry.

Conclusions:

Improving children's oral health should be a public health priority in Poland. Public authorities in a very limited extent participate in the organization, financing, supplying and supervising of dental care. Health promotion programs are ineffective, health needs assessment aren't being done, we observe the lack of cooperation between the key health institutions and lack of tools to identify socio-economic inequalities.

Key messages:

- Research financed by Medical University of Silesia in Katowice.
- The aim of the study was to carry out an analysis of some organizational, financial, social aspects of a dental care in Poland comparing to EU, and to identify the causes of a bad health outcomes.

Healthy public policy competences for public health: interactive and practice-oriented curriculum

Ak'ingabe Guyon

A Guyon[1,2], *R Lessard*[1,2], *M Masse-Jolicoeur*[1], *S Tessier*[1]
[1]Direction de Santé Publique de Montréal, Montreal, Canada
[2]Département de Médecine Sociale et Préventive, École de Santé Publique de l'Université de Montréal, Montreal, Canada
Contact: akingabe.guyon@mail.mcgill.ca

Background:

Developing and implementing healthy public policy (HPP) is one of the practical competences expected of public health professionals in Europe and beyond (ASPHER 2018, Public Health Agency of Canada 2015, US Public Health Foundation 2014). Yet, organizational practices in building public health capacity to promote HPP are seldom documented. In order to improve its HPP interventions, the Montreal Public Health Unit has been leading and evaluating a HPP multidisciplinary community of practice since 2014. In response to participants' requests, we recently formalized a HPP curriculum.

Objectives:

Over a period of 12 months in 2018-2019, our objectives were to: (1) develop and pre-test a competency-based professional development curriculum in HPP for public health staff and interns (2) provide a repository of relevant references (3) identify dynamic pedagogical strategies applicable to a community of practice.

Results:

As community of practice members and facilitators, we developed a HPP curriculum with the support of pedagogical and HPP experts. It was pre-tested and iteratively adjusted with members of the community of practice. We drew content from various disciplines including political sciences, public health, communication studies and public relations. We identified relevant: (1) competences; (2) core concepts; (3)

practical skills; (4) key references; (5) practical case studies, (6) interactive pedagogical strategies such as an open-source online learning system.

Conclusions:

We developed an innovative healthy public policy (HPP) curriculum in order to support an existing community of practice among public health staff. Dynamic pedagogical strategies and a more formal HPP curriculum can support competence development among public health staff, and this can be achieved while relying mostly on in-house expertise. This constitutes a stimulating capacity-building initiative for the enhancement of public health core competences.

Key messages:

- Developing healthy public policy is a core practical competence expected of public health professionals. Yet, organizational practices in building healthy public policy capacity are seldom documented.
- Developing dynamic pedagogical strategies and a more formal healthy public policy curriculum can support competence development among public health staff, while relying mostly on in-house expertise.

Predictors of nursing-home entry for elders in Belgium

Finaba Berete

F Berete[1,2], S Demarest[1], R Charafeddine[1], J Tafforeau[1], H Van Oyen[1,3], O Bruyère[2], J Van der Heyden[1]
[1]SD Epidemiology and Public Health, Sciensano, Brussels, Belgium
[2]Department of Public Health, Epidemiology and Health Economi, University of Liège, Liège, Belgium
[3]Department of Public Health, Ghent University, Ghent, Belgium
Contact: finaba.berete@sciensano.be

Background:

Due to the aging of the population the demand for long-term care services is expected to rise during the coming years. For a better planning of health care resources policy makers have to be aware of risk factors associated to nursing home entry (NHE). The present study aims to identify predictors of NHE in a representative sample of Belgian community dwelling older residents.

Methods:

Date from the participants of the Belgian health interview survey (BHIS) 2013 aged 65 years and over were individually linked with longitudinal data from the Belgian compulsory health insurance data (BCHI) over a 5-year period (2012-2017). Institutionalized BHIS participants were excluded, resulting in a final database of 1,927 individuals. A multivariate Cox proportional hazards model was fit to estimate the hazard of NHE. The model examined the hazard of NHE over the follow-up period in function of predisposing, enabling and need variables observed at baseline. All analyses were done using SAS 9.3 taking into account the survey design settings.

Results:

Over the follow-up period, 169 out of 1,927 individuals entered in NH (56% males, mean age $=74.7\pm0.25$). Significant predictors of NHE were older age (hazard ratio (HR) $=2.40$, CI = 1.23-4.67 and HR = 6.19, 95% CI = 2.75-13.92, respectively for 75-84 years and 85+ years compared to 65-74 years), living condition (HR = 4.28, 95% CI = 1.01-18.19 for living alone), severity of limitation in ADLs (HR = 2.61, 95% CI = 1.39-4.88 for moderate limitation and HR = 2.40, 95% CI = 1.10-5.26 for severe limitation, compared to those without limitation).

Conclusions:

Apart from age and living condition, the ADLs limitations were the strongest predictors of NHE. Public health action to reduce NHE of older people should first of all focus on preventive action at middle age which will reduce activity limitations at later age.

Key messages:

- Risk profiles for NHE are highly dependent individuals.
- NH should be more specialized with qualified professionals.

Access to emergency care units by socially vulnerable patients: a qualitative research

Margaux Vieille

M Vieille[1], M Rotily[2,3], T Apostolidis[1], N Persico[4], A Galinier[2]
[1]Laboratoire de Psychologie Sociale - EA849, Aix Marseille Université, Aix-en-Provence, France
[2]Espace Santé, Assistance Publique Hopitaux de Marseille, Marseille, France
[3]CERESS, Aix Marseille Université, Marseille, France
[4]Pole Urgence Adultes - CHU Nord, Assistance Publique Hopitaux de Marseille, Marseille, France
Contact: margauxvieille9@hotmail.fr

Background:

The increasing prevalence of chronic diseases, the decline in medical demography, the ramp up of new information and diagnosis technologies, together with the growing health social inequalities urge decision makers to rethink the access to emergency care units (ECU) and reduce the rate of multiple admissions, especially for people living in vulnerable conditions. Beyond the medical causes of access to ECU, it is crucial to understand the psychosocial representations of patients and health professionals.

Methods:

23 socially vulnerable patients who have already been admitted within the last 3 months and ECU health/social professionals were interviewed face-to-face by a psychosocial scientist using a semi-directed approach, in 3 hospitals. The thematic content of data was analyzed in order to identify salient social representations of access to ECU.

Results:

27 themes emerged to understand the issue of the access to ECU, joining into 5 main categories: perceived needs for access to ECU, perception of precariousness, the relationship of patients and professionals with the healthcare system, the shared experience of aggressiveness in ECU, expectations in post-emergency support. As regards the needs for access to ICU, several issues were identified: exemption from making upfront payments, needs for listening, support, reinsurance, privacy and consideration of emergency professionals, referral by general practitioners (GP), difficult access to GP, needs for immediacy and timely healthcare services, permanent opening of ECU. As regards the experience of ECU professionals: ambivalent emotions towards socially vulnerable patients, a recurrence of passages leading to a reduced medical attention, a feeling of failure to care for vulnerable patients, coping strategies in caring for these patients.

Conclusions:

Our results bring several leads to improve the organization and the management of healthcare in ECU and in primary care for socially vulnerable patients.

Key messages:

- To identify the psychosocial rationales of access to emergency care units provides several leads to build a more efficient healthcare policy and reduce the burden of overloaded services.
- To reduce the overburden of emergency services can only be achieved by a global approach of the access to both emergency and primary care and a better support after emergency discharge.

Convergence in disability policies in the welfare states Denmark, Sweden, the UK and Australia?

Natasja Koitzsch Jensen

NK Jensen[1], A McAllister[2], D Wadiwel[3], A Elliot[3], G Hwang[3]
[1]Department of Public Health, University of Copenhagen, Copenhagen, Denmark
[2]Disability and Health Unit, University of Melbourne, Melbourne, Australia
[3]Department of Sociology and Social Policy, University of Sydney, Sydney, Australia
Contact: naje@sund.ku.dk

Background:

A state's relation to citizens who are not able to support themselves due to illness is one of the cornerstones of welfare states. However, rising numbers of people on disability benefits is a challenge in many welfare states. The first aim is to investigate how policies around eligibility to disability benefits articulate a concept of 'incapacity to work' across social democratic (Denmark and Sweden) and liberal welfare states (Australia and the UK). Secondly, we wish to explore how the conceptualisation of capacity and incapacity to work shapes prevailing constructions of disability.

Methods:

In this study, we analyse official policy documents from governments, legislation, scientific and grey literature on disability benefit reforms in the selected countries. The analytical framework introduces the notion of decommodification of labour for people with disability and the 'social model of disability' in relation to the constructions of disability in current disability benefit reforms.

Results (preliminary):

Restricting access to disability benefits has been a key feature of the recent reforms across all different types of welfare states. Liberal welfare states are more pervasive in reassessment of previously granted benefits compared to social democratic welfare states. The construction of disability in recent reforms is at odds with the social model of disability.

Conclusions (preliminary)

Across both liberal and social democratic welfare states eligibility for disability benefits is articulated around notions of incapacity to work. Retrenchment of benefits is, overall, most pervasive in liberal welfare states.

Key messages:

- The convergence in social policies across both social democratic and liberal welfare states speaks to the pervasiveness of neo-liberal notions in current social policy.
- The tightening of eligibility criteria for disability benefits poses great financial and health risks to people with illness struggling to support themselves.

Implementation of a new model of management to increase the effectiveness of nursing specialists

Vitaliy Koikov

V Koikov[1], Z Baigozhina[1], A Umbetzhanova[1,2], Zh Bekbergenova[1,2], G Derbissalina[2]

[1]Center for Education & Science Development, Republican Center For Health Development, Nur-Sultan, Kazakhstan

[2]Department of General Practice, Astana Medical University, Nur-Sultan, Kazakhstan

Contact: vitaliy.koikov@gmail.com

Issue/problem:

Nurses play a key role in the system of public health. The total number of nurses in Kazakhstan is 105,441 people (January 1, 2019), which is over 40% of all health workers in the health system of Kazakhstan. The continuing problem of insufficiently effective nursing service (NS) in the country prompted us to develop policy options to increase the NS effectiveness.

Description of the problem:

Key problems of the NS in Kazakhstan include the ineffective management of NS in health organizations, which is associated with an underestimation of the role of nurses in the therapeutic and diagnostic process. There is also a discrepancy in the functioning of the system of nursing education, research and practice with European directives. There are inadequate regulatory acts governing the activities of nurses (including the lack of national guidelines, nursing standards, etc.).

Results:

As a result of analyzing the current situation in the country and summarizing the data from systematic reviews, we were developed the Policy Brief on the issues of implementation of a new model of the NS management. As the key policy options, we proposed: 1. Improving the NS management in health organizations based on a revision of the role of nursing staff in the treatment and diagnostic process; 2. Improving the sectoral qualifications system of nursing specialists in accordance with European directives; 3. Ensuring the development of evidence-based nursing practices with the implementation of generally accepted international standards and models, the development of national guidelines and standards for NS.

Lessons:

The proposed measures found support from the Ministry of Health and were included in the action plans. Each of these policy options contributes to increasing the effectiveness of NS in the health system of Kazakhstan, but these options provide more substantial achievement of the goal of enhancing the role and status of a nurse with their combined implementation.

Key messages:

- Implementation of a new model of the NS management in which nurses and physicions work on an equal footing and independently can significantly improve the efficiency of NS.
- Implementation of evidence-based approaches to the formation of a policy in the field of the NS development gives possibility to increase the effectiveness of the reforms in this field.

The Portuguese HIV/AIDS Programme under austerity

Goncalo Figueiredo Augusto

G Figueiredo Augusto[1], I Aldir[2], J Bettencourt[2], S Dias[3], A Abrantes[4], M Oliveira Martins[1]

[1]Global Health and Tropical Medicine, Institute of Hygiene and Tropical Medicine - NOVA University of Lisbon, Lisbon, Portugal

[2]National Programme for HIV/AIDS Infection, Directorate General of Health, Lisbon, Portugal

[3]Health Promotion, National School of Public Health - NOVA University of Lisbon, Lisbon, Portugal

[4]Health Policy and Administration, National School of Public Health - NOVA University of Lisbon, Lisbon, Portugal

Contact: figueiredo.augusto@ihmt.unl.pt

Background:

The HIV/AIDS Programme has been a core health programme in Portugal leading the country's response to the HIV epidemics since the 1980s. In 2011, the severe financial and economical context forced the government to reorganize central services, including the Ministry of Health, aiming to improve efficiency and reduce costs. All vertical programmes were reformed, including the HIV/AIDS Programme.

Methods:

For the period 2009-2018, we analyse the outcomes of core HIV prevention programmes managed by the National Programme for HIV/AIDS Infection: the syringe exchange programme, HIV testing, the distribution of preventive materials, and financial support to private non-for-profit organisations.

Results:

This paper describes the main features of that reform and analyses selected outcomes, as well as how those financial constraints affected the response to HIV/AIDS. Despite some transitory cuts in spending, the National Programme for HIV/AIDS Infection was able to successfully expand testing and prevention interventions. Strategic partnerships with non-governmental and community-based organisations were crucial to continue delivering adequate HIV testing services and reaching most-at-risk groups.

Conclusions:

The main goals of the National Programme for HIV/AIDS Infection for the term 2012-2016 were reached, including the decrease of new HIV infections, new AIDS cases and AIDS-related deaths, and the country is in a good position to meet UNAIDS's 90-90-90 targets by 2020. Scaling-up access to pre-exposure prophylaxis, improving access and adherence to antiretroviral therapy, and continuously promoting access to HIV testing services and HIV self-testing stand as the main challenges of the National Programme for HIV/AIDS Infection in the near future.

Key messages:

- Prioritise spending under financial constrains can be cost-effective.
- Besides transitory cuts, HIV programme was able to meet its goals.

Transformative governance for public health: A scoping review

Floor Schreurs

F Schreurs[1], *MPM Bekker*[2], *JK Helderman*[3], *M Jansen*[1], *D Ruwaard*[1]
[1]Health Services Research, Maastricht University, Maastricht, Netherlands
[2]Maatschappijwetenschappen, Wageningen University, Wageningen, Netherlands
[3]Public Administration & Political Science, Radboud University, Nijmegen, Netherlands
Contact: f.schreurs@maastrichtuniversity.nl

Background:

As coordination issues arise in an increasingly complex health domain with a growing number of stakeholders involved in health initiatives, WHO proposed a transformation towards a Whole of Society approach. However, this abstract approach lacks practical guidelines to tackle these issues. In domains such as the environmental policy sector, similar transformations were established by applying governance strategies. This study aims to answer, which conditions and arrangements are found in the governance literature for the coordination and evaluation of the transformation of health towards a Whole of Society approach?

Methods:

A systematic search was conducted by combining ’governance’, with adjectives as ’collaborative’, ’adaptive’, ’experimentalist’ and ’reflexive’ in order to target relevant governance theories in JStor, Web of Science, EBSCO and Google Scholar. Based on inclusion criteria two reviewers independently selected articles following PRISMA.

Results:

Analysis of 56 articles showed that transformation should be coordinated by stimulating favourable conditions such as learning and experimenting in networks that cut across traditional boundaries. These conditions and methods can be divided into three categories. First, establish collaborations with government as equal partner by making the inclusion and decision-making process open and transparent. Second, stimulating innovation by engaging local initiatives, and supporting learning, experimentation, reflection and adaptation. Third, ensuring the sustainability of innovation by enabling institutional change.

Conclusions:

To coordinate and evaluate the transformation of health towards a Whole of Society approach, conditions may consist of a combination of collaboration, innovation and institutional change.

Key messages:

- To bring together the fragmented resources for public health, we present emerging conditions for the coordination of a Whole of Society approach as transformative governance strategy.
- The transformative capacity of governance can be found in the combination of the theories as adjectives: collaborative, adaptive, experimentalist and reflexive.

DX Other public health issues

Changes in physical conditions of militars in training: colombian army military school

Laura Castro-Jimenez

LE Castro-Jimenez[1], *PJ Melo-Buitrago*[2], *YP Arguello-Gutierrez*[1], *AY Galvez-Pardo*[1], *S Cortes-Fernandez*[2]
[1]Grupo Cuerpo Sujeto y Educación, Universidad Santo Tomás, Bogotá, Colombia
[2]Grupo Rendimiento Físico Militar, Escuela Militar de Cadetes General José María Córdova, Bogota, Colombia
Contact: laura.castro@usantotomas.edu.co

When beginning the military life, a series of loads of trainings is faced, in addition to supporting the discomforts of climate, fatigue, the change of feeding, schedule, among other factors. Therefore, the objective of the study was to know the changes in the physical condition of the students who begin their military training with military physical training. The investigation was quantitative, longitudinal type. A total of 18 male first-degree engineering cadets from the José María Córdova Military School of Cadets (ESMIC) in Bogotá were evaluated. They were given a pre and post-test of body composition, flexibility, resistance and strength and the training program of the Military school. The findings show that after six months of training the cadets increased body weight (64.6 vs. 65.2) in 0.55 ($p = 0.002$), with a gain of 0.4 kg fat mass (7.9 vs. 8.2g, $p = 0.006$) and 0.2 kg muscle mass (53.9 vs 54.1g, $p = 0.01$), in relation to physical abilities there was a decrease in strength in upper limbs (49.4 vs 45.2 $p = 0.001$) of 4.3 kg and in lower limbs (46.6 vs 43.7, $p = 0.000$) of 2.9 kg, in terms of aerobic resistance (47.8 vs 48.2)and flexibility (30.8 vs 41.3) there was a slight increase without significant differences. The previous results show possible over-training in the ESMIC cadets; due to the change of habits, specifically physical exercise and lifestyle, leading to an increase in weight, in greater quantity in the fat component and decrease in the physical capacity of strength, which can cause early fatigue, being counterproductive when found in some combat or special situation. This is why a specialized systematic training program is the best option for the optimal development of physical abilities, physical adaptation to the effort and prevention of injuries during the practice.

Key messages:

- Injury prevention; Military Personnel; Physical Education and Training.
- Physical Education and Training; Military Personnel; injury prevention.

Tamoxifen and antidepressant’s co-prescription: general practitioners and pharmacist’s alert

Chaslerie Anicet

AC Chaslerie[1], *C Vigneau Victorri*[2], *F Grude*[3], *A Thomasset*[1], *A Even*[1], *J Gourdet*[1], *JP Prieur*[1]
[1]DRSM Pays de la Loire, French National Health Insurance CNAM, Nantes, France
[2]Pharmacology, University Hospital, Nantes, France
[3]Pharmacy, Cancer Dedicated Observatory, Angers, France
Contact: anicet.chaslerie@assurance-maladie.fr

Issue:

Well known drug-drug interaction with some antidepressants, especially selective serotonin reuptake inhibitors which reduce tamoxifen’s effectiveness and associated with an increased risk of death from breast cancer.

Description of the problem:

To identify and characterize the exposure to antidepressants in women with breast cancer treated with tamofixen in a west french area. Retrospective population based cohort study; claims from the French Health insurance database. Women living in Pays de la Loire area, aged 20 years or older treated with tamoxifen for breast cancer in 2018 who had concomitant treatment with antidepressants. Call phone to general practitioner’s and meeting with pharmacist when a high or moderate level drug-drug interaction’s was identified.

Results:

Of 4138 women treated with tamoxifen, 497 (12%) received an antidepressant treatment in 2018, corresponding to 571 co-prescriptions. Of them, 74 (13%) was moderate level drug-drug interaction, 66 (11.6%) high level and 307 (53.8%) weak level.70% of high level drug-drug interaction were due to paroxetine and 43% of moderate level due to duloxetine. For these co-prescriptions, concomitant patient’s exposure was for more than four months in 22% cases. 127 different general practitioners and 152 pharmacists (339 different dispensation's date) were concerned by these drug-drug interactions.

Lessons:

French health insurance medical department has contacted general practitioners or pharmacists concerned by these drug-drug interactions. We informed general practitioners to be aware about women treated with tamoxifen when co-prescription with an antidepressant is necessary, preference should be given to one of them that show little or no inhibition of cytochrome P450 2D6.

Key messages:

- Mediation medication and detection of drug-drug interaction by pharmacist.
- Preferential choice of antidepressant by general practitioner or women treat with co-prescription (tamoxifen and antidepressant).

Knowledge, Attitudes and Beliefs towards Electronic Cigarettes among University Students in Austria

Priyamvada Paudyal

P Paudyal[1], *M Movia*[1]
[1]Brighton and Sussex Medical School, Brighton, UK
Contact: p.paudyal@bsms.ac.uk

Background:

The popularity of e-cigarette is increasing recently, both as an alternative nicotine delivery tool or smoking cessation aid. Austria is a country with a high smoking prevalence; 28% of the population are current smoker and 21% have tried e-cigarettes at least once. In this current context, it is important to understand the opinion regarding e-cigarettes.

Methods:

This cross-sectional survey examined the use, knowledge, attitudes and beliefs towards e-cigarettes among undergraduate students from Carinthia University of Applied Sciences in Austria. The anonymous questionnaire was handed out in 29 classrooms during compulsory lecturers, and completed questionnaire was returned to a provided box in the front of the classroom. Descriptive summary statistics was used to summarize the results using SPSS 24. Statistical significance was considered at $p < 0.05$.

Results:

A total of 528 students were approached and all returned the questionnaire giving a 100% completion rate. 83.7% were female and half (50.2%) were in the age group 20 and 24. 96.6% of students reported being aware of e-cigarettes and 32.4% mentioned trying e-cigarettes at least once. 71.2% reported of ever smoking tobacco. 53.8% disagreed that e-cigarettes are an effective way for smoking cessation and only 10.3% agreed recommending it to a friend or family for smoking cessation. 78.1% believed that e-cigarettes are harmful to the health of those who use them and 58.2% disagreed that the use of e-cigarettes should be prohibited on University Campus premises.

Conclusions:

To our knowledge, this study is the first of its kind performed in Austria. Our study shows that self-reported ever use of e-cigarettes is 1.5 times higher among this population than among the general population in Austria. Majority of participants disagreed that e-cigarettes are an effective way for smoking cessation. There seems a gap in knowledge regarding the e-cigarette which needs to be addressed among the university students.

Key messages:

- In Austria, e-cigarettes use is 1.5 times higher among university students compared to the general population.
- Knowledge gap regarding e-cigarettes needs to be addressed among the university students.

Spatial characterization of the targeting's worst-off au Burkina Faso

Emmanuel Bonnet

E Bonnet[1], *A Nikiéma*[2], *FA Roy*[1], *V Ridde*[3]
[1]Résiliences, IRD, Bondy, France
[2]INSS, CNRST, Ouagadougou, Burkina Faso
[3]CEPED, IRD, Paris, France
Contact: emmanuel.bonnet@ird.fr

Introduction:

In 2014, the Government of Burkina Faso received technical and financial support from the World Bank to test the PBF project with various equity measures. Health equity measures included community based selection of worst-off and user fee exemption for them at the point of service. This selection was carried out in 8 health districts. More than 110,000 worst-off have been selected. Several analyses show that their use of care remains low. Our study aims to characterize the selection of the indigent by considering geographical determinants in order to better understand the weakness of access to care.

Methods:

We have mapped the selection of the indigent based on the geolocation data collected with a GIS. We carried out spatial analyses to measure access to localities, health center and the main access roads. We have also integrated population data and geo-environmental characteristics. All these data were aggregated in 500 m cells to provide all variables on a single scale. A total of 9 variables were generated to characterize the spatial targeting's worst-of. We combined two cluster analyses, i.e., k-means, and hierarchical clustering.

Results:

We obtain a characterization of the selection into four classes. These classes highlight that the community-based selection of the worst-off is unequal in terms of distances to localities, health centres, and isolation. The results refine our knowledge of geographical accessibility to health centres by illustrating that distances to the health care centre are not the only geographical determinants to be considered.

Conclusions:

This study is a contribution to the analysis of the characterization of the targeting of the worst-off. The results suggest that it is important to strengthen support for the most isolated worst-off for an access care. More broadly, this study shows that it is necessary to integrate the geographical dimension into the definition of targeting the worst-off.

Key messages:

- It is necessary to integrate the geographical dimension into the definition of targeting the worst-off.
- It is important to strengthen support for the most isolated worst-off for an access care.

Recognition and Participation of Colorectal Cancer Screening in Turkey: Meta-analysis of Literature

Sevil Aydoğan

S Aydoğan[1], *S Metintaş*[1], *MF Önsüz*[1]
[1]Department of Public Health, Eskişehir Osmangazi University Medicine Faculty, Eskişehir, Turkey
Contact: aydogan.sevil@gmail.com

Background:

The aim of the study was to perform a systematic review and meta-analysis of studies about the proportion of recognition of fecal occult blood test (FOBT) and colonoscopy (CS) methods and participation to them in any period of life for colorectal cancer (CRC) screening in Turkey.

Methods:

PubMed, Web of Science, Google Scholar, Turkey Citation Index and YOK Thesis Center databases were screened both in Turkish and English language to identify relevant studies and key words 'colorectal cancer', 'colon cancer', 'cancer screening', 'information', 'attitude', 'behavior', 'awareness' and 'Turkey' were. Criteria for inclusion in the analysis were; conducted in Turkey, original and cross-sectional, conducted CRC risky groups (having CRC in the first degree patients and

50 and above age), studies that give the number of participants and number of taking FOBT and CS screening in any period of their lives and/or the number of knowing them. The studies that met the criteria were read as double blind. The data were entered into the Open Meta Analyst demo program. Because of $p < 0.001$ in the heterogeneity test, random effects model was used in group analysis of the articles. The proportion and 95% confidence interval of knowing and taking FOBT and CS were calculated from the total number of cases.

Results:

A total of 1176 articles were reached in first review. Duplications and inappropriated studies were eliminated, and 52 studies were selected. Eight studies about recognition FOBT, 16 about participation FOBT, 9 about recognition CS and 17 about participation CS were taken in analysis. After analysis it was found that 1315 of 4334 individuals (19.3%, 95%CI:6.6-32.1) recognized to FOBT, 1174 of 6825 individuals (13.2%, 8.0-18.5) participated to FOBT, 2197 of 5728 individuals (31.7%, 18.2-45.2) recognized to CS and 913 of 8860 individuals (10.0%, 8.1-12.0) participated to CS.

Conclusions:

The proportion of recognition and participation to FOBT and CS were found less than expected.

Key messages:

- The proportion of recognition and participation CRC screening methods is low in risky groups.
- Awareness and participation of screening should be increased in risky groups.

The relationship between causes of procrastination and sociodemographic factors

Thomas Tsiampalis

P Vlachopanou[2], *T Tsiampalis*[1], *E Karagiannopoulou*[2]
[1]Institute of Preventive Medicine, Environmental & Occupational Health, Amarousion, Greece
[2]Philosophy Pedagogy Psychology Section of Psychology, University of Ioannina, Ioannina, Greece
Contact: t.tsiampalis@prolepsis.gr

Background:

In recent decades there has been keen research interest in the concept of procrastination and its impact on the student population with few studies being conducted in the Greek student population. The present study aimed to contribute to our knowledge regarding the causes that bring about academic procrastination and to further explore participants' characteristics regarding these causes.

Methods:

A cross-sectional study conducted in Greece with 628 college students at the University of Ioannina. Specially designed instruments were used to record students' sociodemographic characteristics and causes of procrastination (CP). Factor Analysis (FA) with principal components (PCA) was used to derive the main students' causes of procrastination, though Analysis of Covariance was used to examine the effect of their characteristics on these causes.

Results:

5 main causes of procrastination were identified explaining 48% of the total variation. Students' lack of duty/ low tolerance for frustration was significantly associated with their gender ($p = 0.005$), year of study ($p = 0.048$) and grades ($p = 0.008$), while their dependency/difficulty of claim was significantly affected by students' gender ($p = 0.042$), way of living ($p = 0.034$), place of residence ($p = 0.001$) and their age ($p = 0.006$). Moreover, their place of residence was significantly associated with their

fear of failure ($p = 0.001$) and their difficulties in time management and decision making ($p = 0.049$), with those not living in the place of origin presenting greater values in relation to the aforementioned factors.

Conclusions:

Procrastination is a widespread phenomenon in academic settings that affects differently each gender and is also affected by the sociodemographic factors. This study demonstrates the importance of investigating the causes of procrastination as a concept that helps us understand students' behaviour and patterns associated with it.

Key messages:

- There is a great need for further studies on the causes of procrastination in order to help Universities to design learning environments that will be helpful for their students.
- The college instructors should train students not to procrastinate via preventing interventions.

Ageing and its challenges: Communitary Intervention Group findings and experience in 2017, Porto(PT)

Ana Sottomayor

A Sottomayor[1], *M Perez-Duque*[1], *MM Santiago*[1]
[1]Public Health Unit, Group of Primary Care Centres of West Porto, Porto, Portugal
Contact: anasottomayorr@gmail.com

West Porto Public Health(PH) Unit manages a multidisciplinary intervention group - Communitary Intervention Group(GIC) - that responds to critical life situations. It mainly covers mental and public health problems, often associated with ageing. We aimed to characterise the population of referred cases to GIC in 2017, know their geographical distribution and compare case ratio between parish. Data was provided by GIC and all cases from 2017 were included. We used GPS coordinates and QGIS to map the distribution of cases. Case number was compared between parish through the calculation of ratios (considering population size). 95% Confidence intervals (CI) were calculated by Byar's method to assess differences between parish.

A total of 88 cases were referred to GIC in 2017, mostly by the Police (37,1%). Mean age was 62,3 years(16-94) and 62,9% had > = 60 years. Majority (53,3%) were women. The main problem identified was unsanitary housing(23,6%) and elderly at risk(23,6%), followed by psychiatric alterations(15,7%). Considering elderly at risk, 38,1% was associated with unsanitary housing and 14,3% with psychiatric alterations. Parish ''Cedofeita, Santo Ildefonso, Sé, Miragaia, São Nicolau e Vitória''(CSSMS) had the highest number of cases (33,7%) and ''Lordelo do Ouro e Massarelos'' the highest case ratio (21,96; 95%CI:13,92-32,95). Visually most cases live in parish CSSMS or near social neighborhoods. Case ratios was not statistically different between parish.

The type of referred cases suggests a lack of support to elderly. Immediate attention from health services is needed since this situation leads to a misuse of healthcare services, without a sustained benefit, peaking with health deterioration. More investigation is needed, especially to clearly identify social and health determinants. This is particularly important considering the population ageing and the socioeconomic pressure it perpetuates in future generations, compromising their health.

Key messages:

- Health services must rethink elderly care.
- Promoting quality of life through aging is key to sustainability.

Smoking habits among 5th and 6th degree medical students

Cansu Erden Cengiz

C Erden Cengiz[1], *P Ay*[1], *M Aigbovbiosa*[1], *K Yıldırım*[1], *S Guder*[1]
[1]Public Health, Marmara University School of Medicine, Istanbul, Turkey
Contact: ccansuerden@gmail.com

Smoking is the most common cause of preventable mortality and morbidity worldwide. In the fight against tobacco physicians take active role. The objective of this study is to determine the rate and patterns of tobacco use among students of Marmara University School of Medicine (MUSM). This is a cross sectional study carried out in MUSM. The study population were all students studying in the 5th and 6th grades. Data were collected through questionnaires. The questionnaire form included sociodemographics, tobacco usepatterns, quitting attitudes and experiences. Among 410 students, 328 participated. Among all 56.1% were 5th year and 43.9% were 6th year students. The median age was 24 and 55.8% were female. 22.6% of the participants were current smoker. 33.8% of males and 13.7% of females are smoking (p:0,001). Common reasons for starting to smoke were the influence of close friends (11.3%), curosity (8.2%), stress (4.6%). Of the participants, 8.5% had smoked waterpipe. 28.4% of the current smokers still smoke waterpipe, 46.2% had tried to quit more than once and 13.5% wished to quit but had never tried to quit. 40.2% of the participants whose close friend smokes and %44.4 whose partner smokes are current smokers (p:0.001). %70 of current smokers tried at least one time electronic cigarette (p:0.001).

Approximately one fourt of the students are current smokers, higher in men. Those who smoked cigarettes had high affinity for waterpipe, electronic cigarettes. Electronic cigarette is fast rising trend daily. Starting smoking and quitting is influenced by close friends and partners.

Key messages:

- The primary goal should be to stop the smokers and prevent the start of the smokers.
- Information should be made on the harms of electronic cigarettes and the community should be informed.
